In the afternoon a visit was paid to the works of Messrs. Bergmann & Co. These works are most excellently arranged, and many interesting items were seen. The test-bed and large machine shop was first inspected, where a large number of turbine machines were in course of construction. The turbines themselves are made at another works, and are a combination of a Curtis turbine in the high-pressure portion, and a Rateau turbine in the low-pressure portion. All machines are most carefully ventilated, by air ducts and fans, and particularly the turbine machines, these being made, not in the usual way to force the hot air out of the top of the machine, but to blow it out of the bottom, the outlet being connected to a tunnel discharging outside the engine room: the air is sucked into the machine through a filter. The firm are building a 10,000 h.p. set for the Brussels Exhibition of 1910. In the switchboard department a number of sheet iron boards were seen. A large number of small motors were also in course of manufacture.

The party left Berlin and travelled to Cologne on Friday, July 17th, and on the Saturday morning visited Elberfeld and inspected the Elberfeld-Barmen tramway. The party were met at the station by the engineers of the company, and then inspected the tramway track which is being relaid, Thermit welding being used for the rail joints. A special demonstration of the welding was made. It was noticed that some four or five minutes after the metal has been run the rails are squeezed up through a distance of 5 mm., the usual distance of squeezing usually being much less than this. The party then proceeded to the Power Station which supplies current both to the trams and for lighting in the district. The station contains two horizontal engines by Sulzer Bros., of 1,000 kw. capacity, running at 93 r.p.m., driving each a direct-connected alternator of 1,000 kw. at 4,000 volts, and a direct-current dynamo of 1,000 kw. at 600 volts, so that if both machines are being used the full output cannot be obtained from either. The

Digitized by Google

station also contains a 3,000 kw. Brown Boveri turbo-alternator, and the two first steam turbines on the Continent, these being Parsons machines of 1,250 kw. driving alternators at 1,500 r.p.m.

This tour has been one of the most successful of the series organised by the Students' Section, and their thanks are due to the various firms and their staffs for the great kindness shown on all sides.

THE POST OFFICE AND WIRELESS TELEGRAPHY

IN the course of a speech made in Hull on Thursday on the occasion of the opening of the new General Post Office there, Mr. Sydney Buxton, the Postmaster-General, stated that they hoped to give really substantial reduction in telephone rates to France and elsewhere as soon as the new Channel cable was laid. The reduction in charges for trunk telephone calls at night had been fully justified, as there had been an increase of 68 per cent. in messages sent. After referring to the Bolt Head wireless station, Mr. Buxton said, according to *The Times*, that he had come to the conclusion that it was desirable that at any rate principal wireless stations for communication with ships should not be in private hands, but in the hands of the Government. In order that all interests concerned might be impartially considered, and that no private monopoly might be allowed to grow up, no licences for such stations had been given or promised for more than three years from the present time, and therefore in any case the Government would be able to take the service into its own hands then. But he thought it would be desirable to anticipate that date and take over the stations at once, if it were found possible, as he hoped it might be, to make any arrangement for that purpose which would be acceptable to the Marconi Company and other interests concerned.

Mr. Marconi has explained to a *Times* representative that while it was true that negotiations had been begun by the Post Office with a view to acquiring the Marconi land stations in this country for communication with ships, the offer made was so inadequate that it had not been accepted by the directors of the Marconi Company. Mr. Marconi added that while it is true that the licences have only three years to run, as stated by the Postmaster-General, it would perhaps have been better to explain that they were originally granted for eight years. As the service has been perfectly satisfactory from a public point of view, it seemed, he said, unfair to suggest that the licences to the Marconi shore stations might be terminated at the end of the period for which they were granted.

CITY OF LONDON ENGINEER'S ANNUAL REPORT

IN his annual report upon the work executed by the Public Health Department of the Corporation of London during 1908, Mr. Frank Sumner, the City Engineer, states that the lighting of most of the main thoroughfares by arc lamps was continued throughout the year. The number of the original type "open" electric lamps in lighting at the end of the year, at a cost of £26 each, was 398, being a decrease of two, accounted for by the substitution of the new and cheaper flame arc on the new rest in Aldersgate Street, and the abandonment of one lamp on the Blackfriars Bridge Approach, by the Royal Hotel, the latter being no longer required. In addition to this number, there were 34 "Oliver" flame arcs (mostly experimental) and 18 "Reason" enclosed arcs (experimental) in lighting during the year. These lamps were lighted on 23 days during the year when fog or unusual darkness occurred, at a total additional cost of £146 19s. 2d. The number of defective electric lamps reported during the year was 71. The returns of these defects are made daily by the police; and the City of London Electric Lighting Co. were fined for each failure, the amount deducted from their account in fines during the year being £15 18s. 7d. During the year the flame arc lamp on the footpath by the Royal Hotel, Blackfriars Bridge Approach, was removed, the light from the adjacent high-pressure gas lamp proving sufficient to light this part of the thoroughfare. Owing to a new rest being constructed in Aldersgate Street, at the western end of Falcon Street, the column lamp at the corner of the latter thoroughfare was removed on to the rest, and an "Oliver" flame arc lamp, costing £17 10s. per annum, was substituted for the "open" type of lamp, costing £26. The City of London Electric Lighting Co. substituted an "Oliver" flame arc lamp for an "open" type of lantern on the rest at the northern end of Blackfriars Bridge.

This portion of the report concludes with some particulars of the experimental arc lighting, full details of which were given in our last issue.

With regard to overhead wires, since the year 1899, when the Corporation took in hand the work of supervision, a total of about 25 miles of derelict wires have been removed by the inspector of overhead wires. The number of private owners of overhead wires is now 137, and the number of companies 23. Both have considerably added to their number of spans during the last twelve months, and these now total about 733,828 spans crossing public thoroughfares, as compared with 733,200 last year, and 260,000 in 1899. There has been a net increase of about 755¾ miles of National Telephone Co.'s wires, whilst other companies and private owners have added about 22 miles to their lines. The tendency of the National Telephone Co. is to take down their "open wires" and small cables, and substitute for them heavy cables, the larger and more recent containing as many as 400 wires, the number of wires thus increasing in a greater ratio than the spans. The report also mentions the fact that although the exchange telephone systems of the National Telephone Co. and the Post Office have been greatly extended, there is a continued addition in the number of private "direct" lines. The necessity of an immediate connection for business purposes is one cause of this increase, and there is nothing to prevent such lines being erected by firms having premises in more than one part of the City, or between one or more different firms, subject to licence from H.M. Postmaster-General. During the year no less than 5,602 notifications have been given of defective wires, and the City Engineer points out that, owing to the acids formed in the smoky City atmosphere, the corrosion of exposed metal proceeds far more rapidly than is generally supposed, and the galvanising applied as a protection to pole-stays and cable suspending wires does not last long.

During the year several long spans of wires and cables contravening the bye-law, which prohibits a span of more than 115 yards, have been removed, as have also a large number of cables crossing the roofs belonging to various companies that infringed the bye-laws by being less than 6 ft. in height above the roofs of the buildings. On the roofs of the buildings in the neighbourhood of the Stock Exchange being inspected, unmarked wires were found leading into stock-brokers' offices, which, on being followed up, were found to have been put in by a company owning a new instrument, being a writing machine and a telephone combined, called the "Telewriter." Although a number of these instruments had been installed in various offices, it was found that the company were able to make use of the General Post Office underground cables and the National Telephone Co.'s lines for the purpose of their connections, only one such private line being now in existence in the City. The Amalgamated Radio-Telegraph Co., Ltd., of Salisbury House, London Wall, in the month of May, for the purpose of intercepting their wireless messages, suspended a line across Finsbury Circus from the highest part of the roof of Salisbury House to the top of the flag-post of the "River Plate House" opposite, at a great height above the garden. This wire was put up by the company for experimental purposes only, and remained for about seven months, and has now been removed.

NATIONAL TELEPHONE CO.'S MEETING

THE annual general meeting of the National Telephone Co. was held in London on Thursday, when the report and accounts given in our issue for July 15th were adopted. Mr. George Franklin, the president of the company, who was in the chair, said that the increase in revenue, viz., £94,268, was less than in several preceding half-years, which was largely due to depression in trade, and to some extent to the necessity which the company is now under of making its capital expenditure coincide with the needs of the remainder of its licensed period. The chairman referred to the increase in rates, viz., £5,843, and also drew attention to an increase in the item of rent and maintenance of Post Office wires, viz., from £27,619 to £42,679. This was a result of the arrangement with the Postmaster-General to carry out certain works which the company had the use of, and for which they had to pay rent. On the question of capital expenditure, the company were still willing to spend capital for the Postmaster-General for the year 1912, and afterwards, provided that the full cost of it was borne by the Postmaster-General and no further burden was cast upon the shareholders. With regard to the adverse decision of the House of Lords upon the question of private wires, the company had provided, half-year by half-year, for the royalty which might be claimed ultimately, and in this way neither the accounts of the present half-year, nor those of future half-years, would be affected by this decision. Dealing with the possibility of an earlier purchase of the company's business than 1912, the chairman stated there had been certain pourparlers between the Post Office and the company, but the company were awaiting definitive proposals. The company expected to be compensated for the licensed period which they were asked to surrender for the benefit of the public interest. He observed from a recent question in Parliament that there is a strange misapprehension as to the position of the company in relation to its plant. This, however, would be found to be in accordance with the specifications required by the Government in 1905, when they entered into their agreement, and, as far as they could judge, the company's plant was never in a more efficient position than it was to-day, and certainly there never was a time when they were spending more upon their plant in maintenance than the company were doing to-day.

Electric Lighting of Railway Carriages.—In consequence of the part played by the gas-lighting equipments of the trains involved in some recent accidents, the Prussian railway authorities have decided to convert all their sleeping-cars now fitted for gas lighting (some 170 cars) to electric lighting.

Digitized by Google

LOCAL NOTES

ABERDEEN: *Tramway Accounts.*—The total revenue from the tramways for the year to March 31st, 1909, amounted to £71,680, against £71,930 for the previous twelve months, whilst the working expenses increased by £1,525, being £40,194. Interest and sinking fund charges, however, were less by £1,793, thus leaving the net balance £14,938, against £14,920 in the previous twelve months. This has been added to the renewal account, which now stands at £46,159. The units used for traction purposes were 1,959,932, and the mileage run 1,553,978, an increase in units of 4,074 and a decrease in miles of 12,141 compared with the previous twelve months.

AIRDRIE AND COATBRIDGE: *Embezzlement.*—The late manager of the Airdrie and Coatbridge Tramways Co., Mr. A. Delves, has been committed for trial on a charge of embezzling £200 of the company's funds.

ALTRINCHAM: *Telephone Exchange.*—On Saturday last, at 1.45 p.m., the National Telephone Co. transferred the subscribers connected to its Altrincham exchange to the central battery equipment installed in the new premises, which have been specially designed. The new equipment has been manufactured and installed by the Western Electric Co., of North Woolwich, and is of the No. 1 C.B. type, consisting of 11 subscribers' positions, giving accommodation for 1,100 lines, and three incoming junction positions. The ultimate capacity of the switchboard is 6,000 lines. There are no features embodied in the Altrincham equipment which call for special comment, it being of similar design to that installed at the company's Birmingham-Midland and Hillhead exchanges.

AYR: *Extension of Electric Lighting Area.*—The Council contemplate extending their electric lighting area to include Prestwick.

BATH (RURAL): *Electric Supply.*—The Bath City Council recently intimated their intention of applying for a provisional electric lighting Order for the Rural District of Bath, but the Rural District Council, who already have such an Order, have asked the City Council to purchase it.

BRIGHTON: *Price for Tramway Energy.*—The Electricity and Tramways Committees have been unable to agree as to the price which the latter should pay for electrical energy, and the matter is to be fought out in the Council Chamber. At present the price paid is 1·5d. per unit, and the Electricity Committee offer to reduce this to 1·4d. per unit, but the Tramways Committee claim a greater reduction. The tramways manager protested in his last annual report upon the very high price which the tramway undertaking had to pay for electrical energy.

EDINBURGH: *Electric Light Surplus.*—At the last meeting of the Electricity Committee the question of the disposal of the balance on the electrical undertaking for last year, viz., £2,071, was discussed. A resolution that the amount be applied to sinking fund purposes was rejected, it being agreed to recommend the Council to apply the money to the relief of rates.

EXETER: *Power Supply.*—A sub-committee has been appointed to consider and report upon the question of a special rate for electrical energy for power purposes, if taken at a time that the demand would not involve a serious increase in the generating plant.

FRANCE: *Telephone Communication.*—A British Consular report states that great progress is being made in telephonic communication in the Consular district of Nice, connection having been established between Nice and a great number of communes. Before long a telephone service will be available in every commune.

HESTON AND ISLEWORTH: *Premium Pupils.*—In future, in place of the departmental heads being allowed to take premium pupils, the vacancies as they occur will be put up for competition among those boys who at the elementary schools secured a scholarship, and have completed their course at the secondary school. This applies to the electricity undertaking and other departments of the Council.

LAUNCESTON (TAS.): *Tramways.*—Having broken off the negotiations with Messrs. J. G. White & Co., for the construction of tramways, the Council are considering the advisability of undertaking a scheme of their own at an estimated cost of from £55,000 to £60,000.

LONDON: *L.C.C.: Aldgate-Bow Tramways.*—The work of reconstructing the "G.B." surface-contact tramways in the Mile End Road for the conduit and overhead systems is nearly completed so far as the permanent way is concerned; and it is expected that the service between Aldgate and Bow Bridge will shortly be working.

Motor Generator Repairs.—The Highways Committee draw attention to the condition of certain motor generators erected in tramway sub-stations by the British Westinghouse Electric & Manufacturing Co., Ltd. It is pointed out that the windings of the machines in question have frequently failed, and in order to avoid the risk of dislocating the tramway traffic, it is necessary that arrangements should be made at once to rebuild the stators of the machines. The periods of maintenance under the contracts under which the motor generators were supplied have expired. As the result of negotiations, however, the company has agreed to carry out the work on the understanding that the Council pays for the material, while the company will supply at its own cost the labour required. This will result in about an equal division of the cost of the work between the Council and the company, the cost to the Council amounting to about £333 a machine. The number of machines involved is eleven, and the total cost to the Council will therefore amount to about £3,663. The Highways Committee recommend that this suggestion should be carried out.

Tramways.—The Highways Committee report with regard to the contracts placed with Messrs. Mountain & Gibson, Ltd.: The Council, on May 26th, 1908, October 20th, 1908, February 2nd, 1909, and March 16th, 1909, placed orders with this firm for (i) the supply and erection of sand-drying apparatus, (ii) the supply of six stores transport vehicles, (iii) the supply of four electrically operated car traversers, and (iv) the supply of a forging and annealing furnace for the central car repair depôt, respectively. A receiver of the company has been appointed on behalf of the debenture holders, and he has stated that he is not in a position at the present time to take over the contracts with the Council so as to bind himself and the debenture-holders absolutely; but that it is probable that the company may be transferred as a going concern, the transferees taking over the contracts not completed. The receiver is, however, willing to proceed with the delivery of the goods already made or in process of construction under the contracts in question, provided the Council will agree to treat each delivery as, and when made, as the subject of a separate contract, and to be paid for as such. This course is recommended.

At the meeting on Tuesday, the proposals for seeking Parliamentary powers next session for the construction of new tramways, given in our last issue, were passed.

Fulham: Street Lighting.—The Electricity Committee report that the experiment tried in the Fulham Palace Road of substituting for arc lamps metallic filament lamps attached to the tramway poles is successful. The illuminating effect is equal, if not superior, to arc lighting, while it is appreciably more economical, and there is the additional advantage that the new system removes the obstructions caused by the existing electric light standards. The total number of tramway poles to be fitted is 144, and the number of arc posts to be dispensed with is forty-eight, while the cost of the change is estimated at £507 5s. The annual saving is put down at £259. The electrical engineer is to be instructed to carry out the work.

Hammersmith: Electricity Accounts.—The electricity accounts for the year ended 31st March last show a gross profit of £44,474, and a net profit, after providing for interest, sinking fund, &c., of £4,904.

Woolwich: Mains Extensions.—The Finance Committee of the London County Council recommend sanction to a loan of £3,160, repayable in thirty years, except as to the £160, which is for switchboard extension, and is repayable in twenty years, for the extension of mains to Eltham. The work is already in hand.

MALDEN: *Electricity Supply.*—The Parliamentary Committee recommend the Council to consider the advisability of applying for a Provisional Order, and that Messrs. Talbot & Stevenson, consulting electrical engineers, be engaged to advise in this connection, and also in regard to taking a supply in bulk from the Wimbledon Council. The recommendation was rejected. It may be remembered that the County of London Electric Supply Co. have announced their intention of not proceeding with the Provisional Order for the district which they hold.

MIDDLESEX: *Tramways.*—The Board of Trade have confirmed the County of Middlesex Light Railways (Extension of Time) Order, 1909, reviving the powers granted, and extending the periods limited by the County of Middlesex Light Railways (Lands) Order, 1903, the County of Middlesex Light Railways Order, 1903, and the County of Middlesex (Waltham Cross and Enfield) Light Railways Order, 1906, for the compulsory purchase of certain lands, and extending the periods limited by the last-named Order of 1903 for the completion of certain of the light railways thereby authorised, and reviving the powers granted, and extending the period limited by the said Order of 1906 for the completion of part of the light railway thereby authorised.

MORECAMBE: *The Electrical Undertaking.*—An independent expert is to be called in by the Corporation in connection with proposals for the reconstruction of the electrical undertaking.

PLYMOUTH: *Tramway Accounts.*—The net profits on the Corporation tramways for the year to March 31st amounted to £108, a decrease of £706 compared with the previous twelve months.

PORTSMOUTH: *Tramway Accounts.*—After meeting capital charges there is a net profit shown by the municipal tramway accounts for the year to March 31st of £2,297.

PRESTON: *Purchase of Electrical Undertaking.*—The Streets and Buildings Committee of the Council, which have had under consideration the question of purchasing the undertaking of the National Electric Supply Co., have now reported that they cannot see their way to recommend this course to be taken.

Digitized by Google

ST. IVES (CORNWALL): *Electric Supply.*—Messrs. Foot & Milne, of London, have given notice of their intention to apply to the Board of Trade for an Electric Lighting Provisional Order for this district.

SOUTH AFRICA: *Germiston Electric Supply.*—The Council are in negotiation with the Victoria Falls Power Co. in regard to a supply of electricity in bulk.

SOUTH SHIELDS: *Tramway Energy.*—The Town Council have confirmed the settlement arrived at between the Tramways and Electricity Committees with regard to the dispute as to the account for current for tramway purposes referred to on page 655 of our issue for July 15th.

STOCKTON-ON-TEES: *Electricity Accounts.*—The accounts of the electricity undertaking for the year to March 31st shows a total revenue of £8,174 and expenditure of £4,291. After meeting interest and sinking fund charges, there is a balance of £626, which has been placed to reserve account.

SUTTON: *Increased Charge for Electric Light.*—In regard to the proposed increase of charge for current by the South Metropolitan Electric Lighting & Tramways Co., in consequence of the use of metal filament lamps, the Town Clerk has been instructed to write to the company that it appeared to the Council that the Board of Trade could be approached with reference to the reasonableness of the charges for current, but suggesting, in the first place, a friendly conference with the company upon the matter.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BRAY.—A communication has been received from the Local Government Board concerning the application of the Council for sanction to a loan of £2,600 for the extension of the electric light works. The letter stated that, as regards the sum of £1,162, recoupment to revenue account of cost of extensions defrayed from revenue, these extensions appeared to have been carried out in the years 1904, 1905, and 1906, and the Board could not now with propriety sanction a loan in respect of these works. With regard to the item relating to a switchboard, the Board were of opinion that the cost of providing a new switchboard must be regarded as a maintenance charge, and, as such, must be defrayed out of revenue. The Board were prepared to sanction a loan of £1,000 for gas plant, disconnecting boxes, and contingencies. The Local Government Board is to be written to again on the matter.

BURY.—The Corporation invite tenders for three water-tube boilers, each capable of evaporating 25,000 lbs. of water per hour. Particulars from Mr. S. J. Watson, and tenders to the Town Clerk by August 16th.

DERBY.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £7,300 for the purposes of the electrical undertaking. There was no opposition. Of the sum asked for, £5,000 is in respect of mains, £500 for services, £900 for meters, and £500 for transformers and chambers. It was stated at the inquiry that there had been a considerable increase in the power demand, and that an additional 600 h.p. were waiting to be connected.

L.C.C.—The Highways Committee recommend expenditures of £43,000 and £1,530 for the provision of high- and low-tension cables and feeder pillars respectively for the tramway works purposed to be put in hand during the year 1909-10. It is proposed to invite tenders immediately, and permission is asked to open and deal with these during the summer recess.

The Highways Committee report that, in connection with the operation of motor generators in the tramways sub-stations experiments have been made during the last few months with the use of choke-coils when the machines commence running, with the result that they have been found to be very beneficial in preventing breakdowns at the moment of switching on machines. They therefore suggest that choke-coils should be fixed to twenty-five additional generators, at a cost of £1,500.

MANCHESTER.—Tenders are invited for three five-wire balancers. Particulars from Mr. F. E. Hughes, Secretary to the Electricity Department, Town Hall, and tenders by August 4th.

WALTHAMSTOW.—An expenditure of £6,828 is contemplated upon converting plant, transformer sub-station, high-tension cable, and distributing cables. The last-mentioned amount would cover the laying of distributing cables in thirteen roads.

WOOLWICH.—Mains are to be extended from Weigall Road to opposite Cambridge Road at an estimated cost of £278. £300 is to be spent in extending distribution mains to a number of houses in the borough, which are being fitted with electrical installations during construction.

Miscellaneous

AUSTRALIA.—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, by November 10th, for the supply, delivery, and erection of a branching metallic multiple magneto switchboard at the Petersham Telephone Exchange. Tender forms, specification, &c., may be obtained, and preliminary deposits paid, at the Commonwealth Offices in London, 72 Victoria Street, S.W. A copy of the specification, &c., may be seen by British firms interested on application at the Commercial Intelligence Branch of the Board of Trade, E.C.

HUDDERSFIELD.—Tenders are invited for the erection of telephone lines from the Central Police Station to the Mold Green, Deighton, and Lockwood Police Stations. Particulars from the Town Clerk, and tenders by August 4th.

LONDON: *London County Council: Tramways.*—The Highways Committee recommend an expenditure of £54,750 for the construction of the authorised extension of the Harrow Road tramways to Edgware Road, a distance of 1·14 miles in length. The lines will be upon the overhead system, and it is probable that an agreement will be entered into with the Metropolitan Electric Tramways, Ltd., for a lease of the line, the Council retaining the right to run cars upon it. The expenditure of a further sum of £3,800 for the provision of electric cars on this line is also recommended.

An expenditure of £1,250 is recommended upon the equipment of a tramways permanent way depôt at Battersea.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—Enlargement of fire-station, Rosebery Avenue (£1,900). W. E. Riley, architect, L.C.C. Spring Gardens, S.W.

N.E.—Skating Rink, Hoe Street, Walthamstow. Builders, Good Bros., Hoe Street, Walthamstow, N.E.

S.E.—Adaptation of mission hall, Francis Street, Woolwich, for library. J. R. Dixon, surveyor, Town Hall, Wellington Street, Woolwich.

S.W.—Mission church, corner of Kempson Road and Musgrave Crescent, Fulham. C. G. F. Rees, estate agent, Great Stanmore, Middlesex.

W.C.—Buildings at junction of Kingsway and Kemble Street for L. & C. Hardtmuth, 12, Golden Lane, E.C.

PROVINCES.

BIRMINGHAM.—Skating Rink, John Bright Street. Architect, H. Lloyd, 38 Bennet Hill, Birmingham.

BRIDLINGTON.—Enlargement at High School for Girls (£5,987). Builder, T. A. Moore, Bridge Street, Bridlington.

CARDIFF.—School extensions. Architect, E. W. Corbett, Estate Office, Castle Street, Cardiff.

DEWSBURY.—Tenders are invited for the wiring of the Nurses' Home at the Dewsbury District Infirmary. Particulars from the architects, Messrs. Kirk, Sons & Ridgway, Dewsbury.

GILLINGHAM (KENT).—Additions to schools (£2,224). Surveyor, J. L. Redfern, Council Offices, Gardiner Street, Gillingham.

HARROW.—School (£13,336); also enlargement of Vaughan Road School (£8,121). Builders, H. Knight & Son, Tottenham.

NORTHAMPTON.—Town and county school, Billing Road (£10,679). Architects, Norman & McKewan, 4 Wood Hill, Northampton.

RICHMOND.—Enlargement of Holy Trinity School. The Managers.

SUTTON COLDFIELD.—Skating rink (£6,000). Architect, A. G. Latham, 5A Temple Row, Birmingham.

SWANSEA.—Additions at Union Workhouse, and alterations to Union Offices, for the Guardians.

UXBRIDGE.—A committee has been appointed by the Board of Guardians to report upon the use of electricity for lighting the workhouse.

WOLVERHAMPTON.—School. Architect, F. Fleeming, Bank Chambers, Wolverhampton.

TENDERS RECEIVED AND ACCEPTED

KEIGHLEY.—The tender of Messrs. McPhail & Simpson, Ltd., for the supply of three superheaters and steam piping in connection therewith has been accepted at £304, subject to the consent of the Local Government Board for the necessary loan.

LONDON: *L.C.C.*—The tender of Messrs. Cammell, Laird & Co., Ltd., for 2,250 forged steel driving wheel tyres at 20s. 10d. per tyre, and 100 special tyres for old type wheel centres at 26s. per tyre, has been accepted.

Digitized by Google

The tender of Messrs. Hurst, Nelson & Co., Ltd., for the supply of 260 destination indicator boxes for electric cars at £799 10s. has been accepted.

The tender of Messrs. W. T. Henley's Telegraph Works Co., Ltd., for the supply of cables for tramways in Southwark Street has been accepted at £780. The tender of Messrs. Henley for the supply of cables required in connection with the reconstruction of the Highgate Hill tramways has also been accepted at £1,900, and a tender by Messrs. Reed Bros. for the ducts at £450.

The Highways Committee ask permission, during the summer recess, to open and deal with any tenders that may be received for the manufacture, supply, and delivery of (i) stoneware ducts, (ii) sub-station switchgear, and (iii) motor generators, and for the work of (iv) laying stoneware ducts in connection with the electrification of further portions of the Council's tramways.

A truck, steel underframe, and other fittings, required for an experimental tramcar of a special pattern for use on routes with steep gradients, is to be obtained from Messrs. Hurst, Nelson & Co., Ltd., at £247.

Six specially constructed conduit cleaning machines are to be obtained at a cost of £300. It is estimated that a saving of £2,500 per annum will be effected by their use.

Contracts are to be placed with Messrs. G. Hayward & Co., Ltd., for the supply of ten travelling platforms for painting electric cars at the Holloway car-shed, and forty-one similar platforms for the Norwood car-shed; and with Messrs. Buck & Hickman, Ltd., for the supply of 2,645 lengths of mild steel rails in connection therewith.

Fulham.—The Council have placed an order, through the architect, with Higgins & Griffiths, at £57 10s., for special electric light fittings for the new central library.

Stepney.—The following tenders were received by Stepney Borough Council for the supply of 300 yards 1·0 sq. in. rubber-covered and fireproof cable :—W. Geipel & Co., £315; British Insulated & Helsby Cables, Ltd., £397; Henley's Telegraph Works Co., Ltd., £402; W. T. Glover & Co., £414; Baxter & Gaunter (accepted), £270; Indiarubber, Guttapercha & Telegraph Works Co., Ltd., £419.

Woolwich.—The Council have placed an order with C. A. Parsons & Co., for the renewal of a turbine commutator at £98.

MIDDLESEX.—The County Council have received the following tenders for the completion of the Harrow Road (Wembley) tramway, *i.e.*, from the Swan Inn, Sudbury, to join tramway No. 9 (Order, 1903) :—Thomas Adams, £28,397 12s. 4d.; Clift Ford, £28,611 6s. 1d.; Herbert Holloway, £27,439 9s. 5d.; Dick, Kerr & Co., £28,611 6s. 1d.; George Law, £28,860; Mowlem & Co., £29,852; William Manders, £33,104 19s. 11d.; Underwood Bros., £27,764 5s. 5d.; Charles Wall, £27,280; Wimpey & Co. (accepted), £27,132.

COMPANIES' MEETINGS AND REPORTS

MADRAS ELECTRIC SUPPLY CORPORATION.—In their report for 1908, the directors regret that the contractors have not yet completed their work, although it was anticipated that everything on the direct current side would have been finished by February, 1908, and on the alternating current side for the tramway supply by January 1st last. The buildings and equipment of the main generating station, the sub-station at Mylapore, and the tramway sub-station, are now, however, practically finished. The construction of the main generating station had been so far completed on April 3rd last that the company commenced the supply of electricity to the public from the permanent plant, and it is hoped shortly to supply current to the tramways company, who have entered into a contract to purchase a minimum of one million units of current per annum. The supply to the public commenced with an equivalent of 5,200 8-c.p. lamps connected to the mains. Many applications from other consumers have since been received, and some are already connected. With reference to the company's investment in 4½ per cent. preferred ordinary shares in the Madras Electric Tramways (1904), Ltd., it is satisfactory to note that the tramways are doing well, and this company has recently received a dividend at the rate of 5 per cent. per annum (including ½ per cent. out of surplus profits) on these shares. At the meeting last week, the report and accounts were adopted.

EAST LONDON RAILWAY CO.—In their half-yearly report, the directors state that the electrification of the South London section of the London, Brighton and South Coast Railway is approaching completion, but no official date has yet been announced when it will be opened. No data are available as to the comparative cost of working the single-phase system or the third rail continuous-current system, or of the facilities which they offer respectively to the travelling public. Consequently the directors for the present are unable to make any suggestions of a practical nature on the important question of electrification. At the meeting on Tuesday, the report and accounts were adopted.

UNITED RIVER PLATE TELEPHONE CO.—At the meeting last week the report and accounts given in our issue for July 15th were adopted. The chairman stated that much progress had been made during the year in placing the wires underground, and three new common battery exchanges had been opened.

METROPOLITAN RAILWAY CO.—The total receipts for the half-year ending June 30th, 1909, amounted to £379,487, and the expenses to £193,243. Compared with the corresponding half-year of 1908, the receipts show an increase of £22,700, and the expenses a decrease of £6,537. The expenditure is at the rate of 56·25 per cent. of the total traffic receipts, as compared with 60·36 per cent. in the corresponding period. The net revenue account, after providing for the interest upon the debenture stocks and other fixed charges and for electrical depreciation, shows a balance of £137,075, which permits of the payment of the dividends upon the preference stocks, and leave a balance of £32,564. The directors recommend a dividend upon the ordinary stock, for the past half-year, at the rate of £1 per cent. per annum, and to carry forward the balance of £3,904. The report refers to the Bill of the North-West London Railway Co., which was considered by a Committee of the House of Commons in May last, when the company took an active part in opposing it, and the Committee, after eight days' hearing, decided not to allow the Bill to proceed. The installation of automatic signalling on the Inner Circle is now practically completed, and has resulted in greatly improved punctuality in the running of the trains.

CROMPTON & CO.—At the annual meeting on Monday the report and accounts given in our last issue were adopted. Mr. John Trotter, who presided, said that the disappointing result of the year's working was due to over-production and slackness of trade. He deplored the fact that the Victoria Falls & Power Co. was obtaining its plant from Germany. There seemed no immediate prospect of any considerable improvement.

CITY & SOUTH LONDON RAILWAY CO.—At the annual meeting on Tuesday, the report and accounts given in our issue for July 15th were adopted. Mr. C. B. Stuart Wortley, K.C., M.P., stated the decreases in local bookings on the north of the river seemed to show that the limit of the London County Council tramway competition had not yet been reached, but at Euston and King's Cross the bookings continued slowly to increase. The competition of the tramways and motor omnibuses has become so severe that the question of a general reduction of fares was under consideration.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 to £60 10s.

METAL FILAMENT LAMPS.—Messrs. G. M. Boddy & Co. inform us that in consequence of the increased demand for 16-c.p. and 32-c.p. 110-volt lamps, they have had to increase the accommodation at their London offices. They also state that they continue to get excellent reports of the life of their lamps. A 240-volt 50-c.p. lamp at Partick actually burnt over 9,000 hours without blackening, and even at that advanced age we understand that its death was due to an accident, and not to "natural causes."

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Before Mr. Justice Neville, in the Chancery Division of the High Court, on Tuesday, an application was allowed postponing until after the Long Vacation the petition of Messrs. Pritchetts & Gold, Ltd., for the compulsory winding up of the London Electrobus Co., Ltd. It was stated that negotiations are proceeding between the parties with a view to a settlement.

In the Chancery Division of the High Court on Friday, a receiver and manager was appointed to the Reno Electric Stairways Co., Ltd., until October 31st, 1909.

Mr. E. W. Whittaker, of 3 Portland Street, Southampton, has been appointed trustee in the bankruptcy of W. T. Harris, electrical engineer, 460 and 464 Commercial Road, Portsmouth.

A first and final dividend of 3s. 1d. in the £ was paid in the bankruptcy of George Sutcliffe, electrical engineer, 22 Church Street, Abertillery, Mon., at the Official Receiver's Office, 144 Commercial Street, Newport, Mon., on Wednesday.

A meeting of creditors of the Eldon Electric Co., Ltd., will be held at the offices of Messrs. Dickinson, Miller & Turnbull, 46 Grainger Street West, Newcastle-on-Tyne, on August 5th, at 11 a.m.

Creditors of the Santoni Arc Lamp & Engineering Co., Ltd., are requested to send particulars of their claims to Mr. W. MacIntosh Whyte, 11, Queen Victoria Street, London, or Mr. G. E. Corfield, Balfour House, Finsbury Pavement, London, not later than August 20th.

A first dividend of 2s. in the £ will be paid in the bankruptcy of Arnold Roberts, electrical engineer, 21, North Parade, Bradford, on July 31st, at the offices of J. H. Haley, 29, Tyrrel Street, Bradford.

Creditors of the Electrical Works & Development Co., Ltd., are requested to send particulars of their claims to the liquidator, Mr. R. A. Boughton, 52 Gracechurch Street, London, not later than August 31st.

DISSOLUTION OF PARTNERSHIPS.—Messrs. J. S. Enright & F. Thompson, electrical engineers and commission agents, of

Digitized by Google

68 and 68A Lincoln's Inn Fields, London, have dissolved partnership. Debts by F. Thompson.

PARTNERSHIPS.—Mr. Jens Orten-Böving has taken Mr. Douglas Spencer and Mr. P. R. Cobb into partnership. The style of the firm will henceforth be Jens Orten-Böving & Co. The address of the firm will in future be 9½ Union Court, Old Broad Street, London, E.C. Telegrams: "Jenorten, London." Telephone: London Wall 6480.

Messrs. G. D. Smith and F. W. Bridges, carrying on business as exhibition organisers at 119 to 125 Finsbury Pavement, London, E.C., under the style of Smith & Bridges and the Trade Exhibitions Co. and the Trade Exhibitions Stand Fitting Co., have dissolved partnership. Debts by F. W. Bridges.

"EFESCA" LAMPS.—Messrs. Falk, Stadelmann & Co., Ltd. (Veritas Lamp Works, 83, 85, and 87 Farringdon Road, E.C.), inform us that they have now large stocks of 16-c.p. low-voltage and 32-c.p. high-voltage "Efesca" tungsten lamps, for which new sizes a considerable demand is being experienced. They have also a complete range of the various other candle-powers in voltages from 25 to 260, and also all high candle-power lamps in 100, 200, 300, and 400-c.p. sizes.

CHANGE OF ADDRESS.—The address of the North-East Coast Institution of Engineers and Shipbuilders will, in future, be Bolbec Hall, Westgate Road, Newcastle-upon-Tyne.

ITALIAN CUSTOMS DUTIES.—The Board of Trade are in receipt of an Order of the Italian Ministry of Finance, dated July 5th, providing that mercury vapour electric lamps shall be assimilated for Customs purposes to electric arc lamps, dutiable under No. 241 of the Tariff, at the rate of 60 lire per 100 kilogs.

PLANT FOR SALE.—The Salford Corporation have a 120-kw. direct-coupled steam dynamo for sale. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by August 9th.

The Stockport Tramways Committee desire to dispose of about 120 tons of old tramway rails, points, crossings, &c. Particulars from the Borough Surveyor, to whom tenders by August 12th.

MISCELLANEOUS CITY NOTES

MEXICO TRAMWAYS CO.—A quarterly dividend of 1½ per cent. has been declared.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—A dividend of 5 per cent. per annum, together with an additional dividend of 1 per cent. per annum for the half-year to June 30th, has been declared upon the five per cent. non-cumulative preference shares.

ANGLO-AMERICAN TELEGRAPH CO.—After placing £5,000 to renewals fund, interim dividends of 15s. per cent. and £1 10s. per cent. have been declared upon the ordinary and preferred shares respectively. There will be a balance of £24,414 to be carried forward.

LONDON ELECTRIC WIRE CO. & SMITHS.—An interim dividend at the rate of 5 per cent. per annum is recommended for the half-year to June 30th.

KENSINGTON & KNIGHTSBRIDGE ELECTRIC LIGHTING CO.—An interim dividend of 8 per cent. per annum has been declared upon the ordinary shares for the half-year to June 30th.

IMPERIAL TRAMWAYS CO.—It is announced that no interim dividend will be paid for the first half-year.

MATHER & PLATT.—An interim dividend of 5 per cent., free of tax, is declared upon the ordinary shares for the half-year ended June 30th, being at the rate of 10 per cent. per annum.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO.—A circular has been issued stating that the profits for the first six months of the current year amounts to £47,759, which, after including the balance brought forward from last year, and deducting interest on loans, debentures, &c., represents a net sum of £41,704. Out of this the directors have decided to pay an interim dividend on the preference shares of 2½ per cent., absorbing £17,187. The balance, namely, £24,516, though subject to deductions for depreciation, and a sum to be carried forward, would, in the ordinary state of business, permit the declaration of a small interim dividend on the ordinary shares. In view, however, of the critical position of the coal trade and the possible stoppage of, and damage to other trades which may follow therefrom, the directors do not think it prudent to deal with the balance before the end of the company's financial year.

MONTREAL HEAT, LIGHT, & POWER CO.—The Bank of Montreal has been instructed to announce that the directors have declared a dividend of 1¾ per cent., being at the rate of 7 per cent. per annum, for the quarter ending 31st instant.

CENTRAL LONDON RAILWAY CO.—The directors declare a dividend for the half-year ended June 30th, 1909, on the undivided ordinary stock at the rate of 3 per cent. per annum, on the preferred ordinary stock 4 per cent. per annum, and on the deferred ordinary 2 per cent. per annum.

BRISTOL TRAMWAYS & CARRIAGE CO.—An interim dividend at the rate of 6 per cent. per annum for the half-year ended June 30th has been declared.

LIVERPOOL OVERHEAD RAILWAY CO.—A dividend at the rate of 5 per cent. per annum upon the 1892 preference shares, for the half-year ended June 30th, is announced, carrying forward £4,696.

LIVERPOOL & DISTRICT LIGHTING CO.—An interim dividend at the rate of 4 per cent. per annum, less tax, is announced.

BROMPTON & KENSINGTON ELECTRIC SUPPLY CO.—An interim dividend of 9 per cent. per annum (4s. 6d. per share) upon the ordinary shares is declared for the past half-year.

COUNTY OF LONDON ELECTRIC SUPPLY CO.—An interim dividend for the June half-year, at the rate of 4 per cent. per annum, less tax, is declared upon the ordinary shares.

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY CO.—An interim dividend upon the 4½ and 6 per cent. preference shares has been declared for the June half-year, and an interim dividend on the ordinary shares at the rate of 5 per cent. per annum, less tax.

PARLIAMENTARY INTELLIGENCE

HOLYWOOD TRAMWAYS.—This Bill, which seeks an extension of time for the construction of tramways authorised in 1904, was before a Select Committee of the House of Lords on Thursday. The Belfast and County Down Railway Co. applied for, but were refused, a *locus*, and there was no further opposition. The extended period allowed is three years.

LONDON ELECTRIC SUPPLY BILL.—Mr. H. J. Tennant, Parliamentary Secretary to the Board of Trade, has a motion on the paper in the House of Commons that the London Electric Supply Bill shall be referred to a Select Committee of five members, three being nominated by the House and two by the Committee of Selection.

GATESHEAD & DISTRICT TRAMWAYS BILL.—This Bill was before the Unopposed Committee of the House of Commons on Monday, and was ordered to be reported for third reading. The Committee struck out a clause giving the company power to adopt the trackless trolley system for the reason that the Corporation had no power of purchase. An agreed clause was in the Bill to the effect that the Corporation would have to give its consent to the adoption of the trackless trolley system, and that when this was asked for the question of purchase would be settled. The Committee did not view the clause with favour, however, and, as mentioned above, struck it out.

WEST KENT ELECTRIC POWER BILL.—This Bill was before the Unopposed Committee of the House of Commons on Monday, and was ordered to be reported for third reading.

PROGRESS OF ELECTRICAL BILLS.—The Edgware and Hampstead Railway Bill is now unopposed.

The Central London Railway Bill was read a third time and passed in the House of Lords on Monday.

The Holywood Tramways Bill was read a third time and passed in the House of Lords on Tuesday.

The Torquay and Paignton Tramways Bill was read a second time in the House of Commons on Tuesday.

APPOINTMENTS AND PERSONAL NOTES

On the recommendation of the Tynemouth Electricity Committee, the salary of the Electrical Engineer is to be reduced from £300 to £250 per annum. This is as the result of an arrangement with the Newcastle Electric Supply Co., under which the Corporation will not run their generating plant for two years, but take a supply in bulk from the company. Consequently, the staff at the works has been reduced. Should a credit balance be shown by the accounts to March, 1910, the question of an increase of the salary of the Chief Engineer will be taken up.

Dr. T. C. Baillie, M.A., at present head of the physics and electrical engineering at the Sunderland Technical College, has been appointed Principal of the Croydon Polytechnic, in succession to Dr. Beckit Burnie, who has been appointed to the Brighton Municipal Technical College. The salary is £300 per annum, rising to £350.

Woolwich Borough Council received 106 applications for the position of two charge engineers in the electricity department, at a salary of £90 per annum, rising by annual increments on approved service of £10 to £140 per annum. Messrs. G. Bartholomew, Engineer-in-charge, Messrs. Dorman & Long, Middlesbrough, and Mr. C. P. H. Bowmaker, Engineer-in-charge of the Torquay Electricity Works, were appointed.

Fatality at the Stuart Street Works, Manchester.—An inquest was held on Monday morning as to the death of John Davies, an employee of the Manchester Corporation Electricity Department, who was killed by electric shock while engaged in moving some transformers on the gallery of the Stuart Street generating station. It appears that, although warned of the presence of live terminals and spark-gaps in the gallery, the deceased had gone inside the rail guarding these, and had received a shock from a stud at a pressure of 3,750 volts, which caused instant death. Evidence was given to the effect that there was no necessity to go inside the rails to move the transformers. The jury returned a verdict of accidental death.

THE ELECTRICAL INDUSTRY IN BERLIN, 1908

A BRITISH Consular report upon the trade and commerce of Berlin during 1908 deals at length with the electrical industry. The report states that the year 1908 brought with it a satisfactory amount of employment for the electrical works situated within the Berlin Consular district, which are among the largest of their kind in Germany, a fact that would seem to prove that an otherwise unfavourable market is not prejudicial to the use of electricity. Important contracts were concluded with Government and municipal authorities, whose activity is, as a rule, not dependent upon market considerations, and who, indeed, prefer to order in times of depression when industrial concerns are not making large demands upon the money market. However, towards the close of the year, the gradually increasing depression also began to affect this industry, more especially in regard to the larger types of machinery, and the submission to the Reichstag of proposals for the taxation of electricity only increased the general reserve observed by possible customers. The value of the turnover of the manufacturing concerns, as well as the number of electrical fittings and accessories manufactured, steadily increased, and good progress was made in the construction and sale of heating appliances similar to those extensively used in the United States. Business in cables was satisfactory, but the value decreased in conformity with the abatement in the prices of raw materials; high-tension cables were especially in demand, and the newly introduced enamelled wire found increasing favour.

In the manufacture of lamps keen competition continued, but metal filament lamps commanded extensive sales, and large orders were received and carried out for the electrical equipment of blast furnaces and steel works. Turbo-dynamos are being introduced on an ever-increasing scale in iron foundries and other important works throughout the country, while the electrically driven reversible rolling mills have, it is said, fulfilled all expectations. A number of electric hauling machines for main shafts with a hoisting capacity of 81,000 tons per day (day shift) were constructed and supplied principally to mines having water pumping works, the textile and paper-making industries taking an increased number of small and middle-sized motors.

The electrification of railways made further progress in 1908, during which year the Prussian Government ordered a fairly large number of accumulator cars intended primarily for augmenting the service on certain lines and for coping with the suburban traffic of medium-sized towns. On the line from Basle to Zell (12½ miles), which the Baden Government converted into an electric railway, an alternating current system has been adopted. In Berlin and the suburbs the expansion of the electric underground and elevated railways has proceeded apace, while of the 2,330 miles of tram lines in Germany at the end of 1908, 90 per cent. were driven by electricity, 2·5 per cent. by steam, 3 per cent. by horses, and the remainder by all three systems combined. Numerous orders for the erection of central electric power stations abroad were placed with German firms in the course of the year, steam turbines being in almost every case preferred to ordinary reciprocating engines such as were formerly employed for plant of this kind, while good contracts were obtained for a number of turbo-generators up to a capacity of 7,500 kilowatts and for five converters each of 9,000 h.p. and 70,000 volts.

The total consumption of electrical energy in Berlin during 1908 is put at 155,115,135 Board of Trade units, compared with 142,921,816 units in 1907, and 128,103,848 units in 1906. The figures for all the large towns in Germany have increased to a similar extent.

In the course of the year two establishments known as "Elektrotreuhandbanken" (electric trustee banks) were established under the auspices of the great German electric companies, this new description of bank having for its object the providing of financial means for the erection, extension, and improvement of electric works by making advances upon guarantees and stocks deposited, bonds being issued on the security of the latter for the purpose of obtaining the requisite capital. The principal object of these "trustee" banks is to advance to large consumers in the electrical industry the money they may require for beginning and carrying out costly works. As already stated, the capital needed for the loans is to be obtained by mortgage bonds, secured in the first place by the stocks in hand, and secondly by the share capital which is to be invested in trustee stocks. As the shares, however, will most probably be retained by the electric works concerned, the entire business resolves itself into a transaction enabling these companies to raise the funds they need in order to assist and open larger credits to their customers, the formation of separate banks evidently having been decided upon as the mostly likely method of facilitating the placing of bonds. These facilities for obtaining cash advances are to be extended principally to municipalities and other public bodies, so that the bonds will be to all intents perfectly secure while at the same time these authorities will be encouraged to proceed with any plans for the erection of new or the extension of old electrical plant which they may have under consideration without the necessity of issuing new loans for that purpose.

TAX ON ELECTRIC LAMPS IN GERMANY

AS we announced in our issue of July 15th, the German Finance Bill, including, as one of its provisions, a tax on illuminating apparatus, was passed by the Reichstag on July 10th, and by the Bundesrat on July 12th. The tax on electric lamps, arc-lamp carbons, and incandescent mantles will come into force on October 1st next, and is expected to bring in a revenue of 20 million marks (approximately £1,000,000) per annum. The methods by which the tax will be administered will be published in August. Carbon and metal filament lamps, Nernst glowers, mantles for gas, spirit, and petroleum burners, arc-lamp carbons, and mercury-vapour and similar lamps, come under the tax, when intended for use inland only.

The amounts of the tax are as follows :—

(*a*) On electric incandescent lamps or glowers :—

	Carbon filament lamps.	Metal filament lamps, Nernst glowers, etc.
(1) Up to 15 watts	5 pf. (0·6*d.*)	10 pf. (1·2*d.*)
(2) From over 15 up to 25 watts	10 ,, (1·2*d.*)	20 ,, (2·4*d.*)
(3) ,, ,, 25 ,, 60 ,, ...	20 ,, (2·4*d.*)	40 ,, (4·8*d.*)
(4) ,, ,, 60 ,, 100 ,, ...	30 ,, (3·6*d.*)	60 ,, (7·2*d.*)
(5) ,, ,, 100 ,, 200 ,, ...	50 ,, (6*d.*)	1 mark (1/-)
(6) For lamps of higher consumption, for every further 100 watts	25 ,, (3*d.*)	40 pf. (4·8*d.*)

(*b*) On incandescent mantles for gas and similar lamps :—

10 pf. (1·2*d.*) per piece.

(*c*) On arc-lamp carbons :—

(1) Plain carbons...	60 pf. per kg.	(3·27*d.* per lb.)
(2) Impregnated carbons	1 mk. ,,	(5·45*d.* ,,)

(*d*) On mercury-vapour and similar lamps :—

Up to 100 watts, 1 mk. (1/-) per lamp; and for lamps of higher consumption, 1 mk. for every further 100 watts.

It is expected that the tax will be imposed by means of revenue labels or stamps, which will be affixed to the packing of the article by the manufacturer before it leaves his works, as proposed in the original Government Bill (see ELECTRICAL ENGINEERING, November 19th, 1908, Vol. IV., p. 677). On the other hand, the Bundesrat is empowered to determine the amount due from the manufacturer by means of an examination of his books, and it is hoped that this will be done generally in the case of both arc-lamp carbons and incandescent lamps. Imported articles subject to the tax must be circulated in the country only in packing with the stamp affixed. Exported articles will not, of course, be taxed; but, nevertheless, the manufacturer must inform the revenue officials of the number of articles leaving the works for export. The tax paid on articles which have been returned to the manufacturer as faulty will be refunded. A section in the Act states that directly the law comes into force manufacturers can demand from their customers an additional sum over that due under the contracts to cover the amount of the tax if no other arrangement has been come to.

Electric Railway from Rome to the Sea-coast.—According to *The Times*, the Communal authorities of Rome have made a contract with a Belgian firm for the construction of an electric railway to run from the Porta San Paolo to the sea-shore a little beyond Ostia, with two or three stations on the way. The railway is to be completed before the end of 1911. It is to be a double line, capable of carrying fairly frequent trains, which will do the whole journey in half an hour. The line will be the property of the Belgian company for forty-five years, during which time the Commune of Rome is to receive 12 per cent. of the gross profits, and at the end of that period it is to be handed over to the Commune. The contractors will also undertake to make a road by the side of the line for ordinary traffic, and to establish hotels and bathing establishments on the site of the new watering-place.

Electrical Apparatus at the Exhibition of the British Medical Association, Belfast.—Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster), have an interesting display of electromedical apparatus at the annual exhibition of the British Medical Association, at Belfast, which included their latest Röntgen-ray apparatus for instantaneous radiography and the production of unidirectional high-tension current without the aid of induction coils and interrupters. Both these functions are fulfilled by the new outfit with the rotary high-tension rectifier, referred to on page 677 of our last issue. A cheaper outfit, with a 16-in. spark coil and Wehnelt interrupter, is also shown, and various tube stands, in which ample protection is afforded both to patient and operator. Another novelty is a clinical temperature recorder. The outfit comprises a platinum spiral in a quartz glass tube, known as the "resistance thermometer," which is inserted into a suitable part of the human body, a 4-volt accumulator battery, a regulating apparatus, and a recording milli-voltmeter. Messrs. Siemens Brothers & Co. also exhibit radium, radio-active substances with applicators for treatment, and radio-active earth for local application, &c.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 22nd, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

14,463/08. **Cut-out for Trolley Circuits.** W. Barraclough. In order to disconnect the trolley wire from the supply in case of breakage, the "up" and "down" trolley wires on each section are coupled together at the end furthest from the source of supply, so that feeding is from one end only, and an electromagnetic switch is provided, which is held on by a shunt coil connected to the near end of the conductor to which the feeder is not attached, so that a break in either overhead wire causes the switch to open and interrupt the feeder circuit. One claim, two figures.

20,447/08. **Cables with Copper and Aluminium Conductors.** C. J. Beaver and E. A. Claremont. Cables with conductors composed partly of copper strands and partly of aluminium strands. The aluminium strands are placed outside in cases where the insulating material is indiarubber, as it is found that the aluminium has less deteriorating action on the indiarubber than copper. Two claims, one figure.

22,551/08. **Electric Heating and Cooking Apparatus.** E. Coiseur. Cooking and heating apparatus, in which the resistances take the form of elongated exhausted crystal tubes, containing metallised carbon filaments of such proportions that they are not brought beyond a dull red heat. One claim, three figures.

23,726/08. **Metal Filament Lamps.** British Thomson-Houston Co. and H. H. Needham. The filaments are made by a squirting process from tungsten in a powdered form, with a special binding material composed of an amalgam of cadmium, bismuth, and mercury in certain specified proportions, which are found to enable very fine filaments suitable for high voltage lamps to be squirted. Four claims, no figures.

24,211/08. **Metal Filaments.** Soc. Française d'Incandescence par le Gas (System Auer). This patent covers a method of elimination of the hydrogen occluded in metal filaments and their supports by heating to at least a red heat in an inert gas before introduction into the bulb, and also the removal of further residual gas by a second exhaustion of the bulb after a period of rest. Two claims, no figures.

26,796/08. **Cable Connectors.** J. Stratton and E. A. Claremont.—Mechanical connectors for stranded cables, consisting of a metal tube with the outer surface tapped at each end and split in half longitudinally. Two outer shells fit over the ends of the tube and the interiors of these respectively are tapped to correspond to each end of the tube and the outer surfaces of which are threaded; one thread being in the reverse direction and a nut which fits over the shells threaded internally at each end corresponding to the threads of the shells. Two claims, seven figures.

28,378/08. **Wireless Telegraphy.** G. Eisenstein. Wireless telegraph installations for the simultaneous mutual transmission and reception of messages, each consisting of a double station with separate sending and receiving plant at some distance apart, but connected by a wire. The transmitting station is provided with a higher mast than the receiving station, and is operated from the receiving station by means of the connecting wire, which is in the signalling box circuit. Two claims, one figure.

4,122/09. **Arc Lamps.** Körting. With the object principally of preventing humming and chattering in the mechanism of alternating-current arc lamps of a particular type, one or both of the armatures of the lamp magnet has upon it rings or windings of conducting material, which have a damping effect. Two claims, two figures.

9,516/09. **Arc Lamps.** H. P. Bleckly and W. Brown. The object of this invention is to avoid sticking of the feeding mechanism in a certain class of arc lamp, when there is not sufficient rush of current after feeding to enable the series core to withdraw the near tooth of the click from the ratchet wheel. A subsidiary cut-out coil is provided to break the circuit as the shunt current increases, owing to undue lengthening of the arc. Seven claims, four figures. The type of lamp in question (Abbey) was described in the supplement to Electrical Engineering of October 29th, 1908.

Opposition to Grant of Patents

25,854/08. **Metal Filaments.** Siemens & Halske Akt.-Ges. Opposition to the grant of this patent has been entered. The specification describes a process of making ductile filaments by coating the tungsten particles with a ductile metal, and was abstracted in Electrical Engineering, June 3rd, 1909, page 519.

2,216/09. **Production of Long Arcs.** Centralstelle für Wissenschaftlich-Technische Untersuchungen Ges. Opposition to the grant of this patent, which relates to the production of long arcs such as those used in the fixation of atmospheric nitrogen, has been entered.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Dynamos, Motors, and Transformers: British Thomson-Houston Co. and Garton [Regulation of motors] 14,700/08; Conrad [Transformer for vapour apparatus] 7,630/09.

Electric Ignition: Deniéport [Distributors] 18,812/08.

Heating and Cooking: Cooper and Sharp [Resistances] 6,106/09.

Incandescent Lamps: Marietti [Soldering of filaments to electrodes] 14,483/08.

Instruments and Meters: Lux [Bolometric measuring instruments] 21,586/08; Guggenheimer and Gossen [Alternating-current instruments] 5,413/09.

Storage Batteries: Bimeler, 16,529/08.

Switchgear, Fuses, and Fittings: Timar and Von Dreger [Motor-starter] 14,513/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*), [Electromagnetically operated switches] 16,[illegible]/08; Bayliss [Lamp-holders, &c.] 20,877/08; Davey [Flash signalling key] 22,345/08; Thursfield [Universal joints for fittings] 25,279/08.

Telephony and Telegraphy: Siemens Bros. & Co. (*Siemens & Halske A.-G.*), [Telephone exchanges] 1,270/09, [Telephone installations] 6,878/09, [Heat coils] 8,108/09, [Switch plugs], 9,592/09.

Traction: Blackall and Jacobs [Signalling] 27,436/08; Sassenberg [Tramway points] 1,040/09; Johnson & Steele Brown [Tramcar lifeguards] 3,280/09; Siemens Brothers & Co. (*Siemens & Halske A.-G.*) [Point and signal locking device] 3,567/09; Bennett, Estes and Evans [Trolleys] 5,018/09.

Miscellaneous: Berry [Suction-gas producers] 14,405/08; Ravenshaw, Middleton and Townsend [Magnetic clutches] 14,530/08; Cruse [Superheaters] 20,148-9/08; Cooper [Smoke-consuming forced draught apparatus] 20,555/08; Buchanan and Wilson [Speed reducing gear] 25,255/08; A. G. Stahlwerke Weissenfels *vorm.* Göppinger & Co. [Electric chain welders] 2,642/09; Siemens Bros. Dynamo Works (*Siemens Schuckertwerke Ges.*) [Driving of looms] 10,269/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: Siemens Schuckertwerke-Ges., 15,605/08; Jaburg, 15,880-1/09.

Storage Batteries: Marseille and Gouin [Supporting active material in alkaline accumulators] 15,373/09.

Switchgear, Fuses, and Fittings: Lamme [Controllers for induction motors] 14,579/09.

Miscellaneous: Felten & Guilleaume-Lahmeyerwerke A.-G. [Petrol electric apparatus] 15,282/09.

Amendment Made

5,459/09. **Maximum Current Indicator.** McClelland. This specification has been amended by the inclusion of the name of Ferranti, Ltd., as joint inventors.

Expiring and Expired Patents

The following Patent expires during the current week after a life of fourteen years:—

14,627/95. **Electric Fire Alarms.** A. C. Brown and G. R. Neilson. The calling apparatus contains a rapid electrically worked make and break apparatus, which actuates a telephone at the receiving station. The call signal is sent automatically when the glass is broken.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: C. D. Budd [Conduits] 7,898/02; A. D. Shuter [Splicing cables] 7,938/02.

Dynamos, Motors, and Transformers: British Thomson-Houston Co. (*Moody*) [Cooling transformers] 6,693/00.

Switchgear, Fuses, and Fittings: H. Pieper [Switches] 7,827/03.

Telephony and Telegraphy: R. Hutchinson and J. H. Wilson [Microphone and telephone for the use of the deaf] 7,063/99.

Traction: H. W. Falk [Cast welded rail joints] 8,152/98; W. H. Travers [Permanent way] 8,033/02; A. J. Boult (*Miller, Miller, Price, Failing and Council*) [Railway signals] 8,066/02.

Miscellaneous: Otis Elevator Co. [Electric lifts] 8,190/02; Siemens Brothers & Co. and F. Hird [Synchronous control apparatus] 8,362/02; A. Tuerk [Electric clocks] 8,389/02.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

Engineers and managers of electric supply companies are being asked by Board of Trade auditors to sign a certificate to the effect that no undue preference is being given to consumers in respect of charges for electric supply. (Page 696.)

The "Telectrograph," an apparatus for photo-telegraphy, devised by Mr. T. Thorne Baker, embodies a number of improvements in this interesting branch of electrical work. The half-tone illustration to be sent is photographed on to lead foil, the surface of which is afterwards pressed flush. The foil is wrapped round a cylinder, and a contact which travels over the surface in the usual way causes a series of impulses to be sent through the line. These impulses are electrolytically recorded on a prepared paper sheet wrapped round the receiving drum. We understand that this apparatus is in practical use between London and Manchester for transmitting photographs for the *Daily Mirror*. A wireless system of photo-telegraphy on the same principles has also been devised. (Page 697.)

Among the Papers read at the Liverpool meeting of the Institution of Mechanical Engineers was one by Mr. H. W. Wilson on electric driving in textile factories. (Page 699.)

Mr. A. H. Seabrook has revised the tariff and system of charging at Marylebone. (Page 701.)

At a special meeting of the Institution of Electrical Engineers on Thursday, resolutions were passed to give effect to the Council's decision to make the necessary alterations in the Institution's new building, and to rebuild the lecture theatre so that it shall be quite suitable for the requirements of the Institution. The new theatre will be even larger than that of the Institution of Civil Engineers, in which the meetings are held at present. (Page 701.)

A correspondent sends us figures showing the economy obtained in his works by the substitution of electric motors for a gas engine. (Page 702.)

On Thursday last, Col. Sir Edward Raban presented the certificates to the successful students of the

Digitized by Google

Crystal Palace Co.'s School of Engineering, and the workshops and drawing-offices were open to inspection. (Page 702.)

An analysis of the telegraph returns of various countries of the world yields some interesting figures showing the volume of telegraphic business. In Great Britain, for example, over 90 million telegrams are dealt with in a year, as compared with 62 million for France, and 54 million for Germany. (Page 702.)

An article by Mr. C. Hughes describes a recent modification of the "lamp flashing" system of clearing a local connection when a subscriber's line is required for a trunk call, which is now used in the most modern central battery exchanges of the National Telephone Co. (Page 703.)

After a lengthy discussion, the Brighton Corporation have fixed the charge of tramway energy at 1·4d. per unit.—The Devonport & District Tramways Co. were summoned last week for discontinuing a service of cars upon lines leased by the Corporation. The magistrates have reserved their decision.—The Dover Corporation have informed the Board of Trade that they do not consider tramcar speed-indicators necessary.—In answer to a communication from the Local Government Board *re* a loan for public lighting, the Finchley Council object to the Board's suggestion that gas is preferable, and hint that such a suggestion is exceeding their function.—The cost of street lighting at Islington is to be reduced by £3,700 per annum.—Salford tramways show net profits for 1908-9 of £17,264, a decrease of nearly £10,000 compared with the previous year. (Page 704.)

York Corporation require 18 double-deck electric tramcars and one watering cart, and cables are required at Grimsby. A loan of £18,922 has been sanctioned to the Middlesbrough Corporation. Loans of £1,250 and £5,750 are sought by the Longton & Carlisle Councils respectively. (Page 706.)

Dividends are announced by several of the London tube railway companies, and also by a number of London electric supply companies. The net revenue of the Great Northern and City Railway Co. for the June half-year was insufficient to meet the Company's fixed charges by £3,209. (Page 707.)

The lead works of Messrs. Blackett & Wilson, Ltd., of Hebburn-on-Tyne, has recently been converted to electric driving, and the sheet lead rolling mill is the first mill of its kind to be electrically driven in this country. (Page 709.)

The following books are reviewed in this issue:—"Electricity in Factories and Workshops," by A. P. Haslam; "Lecture Notes on the Theory of Electrical Measurements," by W. A. Antony; "Electrical Laboratory Course," by R. D. Archibald and R. Rankin; "Ein Neues Schnellbahn System," by A. Scherl; "Der Schutz der Hochspannungsanlagen gegen Blitz und Uberspannung," by H. Zipp; "Die Elektrizität in der Landwirtschaft," by W. Fuhrmann; and "The Influence of Metallic Filament Lamps on the Electrical Industry and on Street Lighting." (Page 711.)

Improved apparatus has been devised for taking instantaneous radiographs. An equipment for veterinary work, capable of taking radiographs with an exposure of only 1/10 of a second, comprises a 14-in. spark coil, taking 90 amperes at 220 volts on the primary, and delivering 100 milli-amperes to the Röntgen tube, the target of which has to be especially designed to withstand the high intensity of the cathode rays. (Page 712.)

A compact form of enclosed motor-starter, with some special features, is described on page 712.

Among the specifications published by the Patent Office was one by S. Marietti for a method of fusing metal filaments to their supports or leading-in wires in the open atmosphere. The wire is flattened and rolled into a tube at the end, and this is fused round the filament with an arc, a jet of air being used to protect the filament from the hot gases. Automatic speed regulation of motors by means of resistances in the shunt field circuits controlled by centrifugal governors is the subject of a specification by the British Thomson-Houston Co. G. Cooper and F. Sharp have one relating to the construction of metal strip resistances for heating and cooking apparatus, and an arrangement for driving looms, comprising a spring mounted motor and a belt-tightening device, is described in a specification by Siemens Bros. Dynamo Works, Ltd. In consequence of opposition, the grant of a patent to the firm of Robert Bosch for magneto armatures with ends and spindles of non-magnetic steel has been refused. (Page 714.)

AUDIT OF ELECTRIC LIGHTING COMPANIES' ACCOUNTS

A POINT of interest and some importance has arisen in connection with the Board of Trade audit of the accounts of electric lighting companies. It appears that engineers and managers of electric lighting companies are being asked to sign a certificate to the effect that no preference is being given to any consumers contrary to the provisions of Sections 19 and 20 of the Electric Lighting Act of 1882, and, further, that no supply is being given outside the area authorised in the Provisional Order contrary to Section 4 of the Electric Lighting (Clauses) Act. The latter point is of minor importance, and does not enter into consideration here. The main point is as to preferential charging. Sections 19 and 20 of the Electric Lighting Act, 1882, read as follows:—

19. *Obligation on Undertakers to Supply Electricity.*—Where a supply of electricity is provided in any part of an area for private purposes, then, except in so far as is otherwise provided by the terms of the licence, order, or special Act authorising such supply, every company or person within that part of the area shall, on application, be entitled to a supply on the same terms on which any other company or person, in such part of the area is entitled under similar circumstances to a corresponding supply.

20. *Charges for Electricity.*—The undertakers shall not, in making any agreements for a supply of electricity, show any undue preference to any local authority, company, or person, but, save as aforesaid, they may make such charges for the supply of electricity as may be agreed upon, not exceeding the limits of price imposed by or in pursuance of the licence, order, or special Act authorising them to supply electricity.

Section 6 of the Electric Lighting (Clauses) Act prescribes that the accounts shall be audited by some competent and impartial person appointed by the Board of Trade, to whom all the requisite information for the purpose of the audit shall be afforded. The section also prescribes that the Board of Trade may make and vary regulations as to the time at and the mode in which the audit shall be conducted.

Before discussing the certificates referred to above, reference may be made to a circular sent to the secretaries of electric supply companies throughout the United Kingdom in December, 1907, in which it was suggested that the auditor elected to act in the ordinary way on behalf of the shareholders might act at the same time as the official Board of Trade auditor. This, it was suggested, would reduce the company's expenses, as the cost of the Board of Trade audit has to be borne by the company. The proposition, however, was not, we believe, taken up with avidity by the companies, and in many cases separate Board of Trade auditors are appointed. It will be seen that the companies who have not agreed to the appointment of their auditor in

Digitized by Google

this dual capacity may have saved themselves some trouble and annoyance.

The demand by Board of Trade auditors that engineers and managers of company undertakings should sign a certificate declaring that they have not broken the law during the year in respect to preferential charging raises a very controversial point once again, viz., the legal definition of "undue preference." This is an exceedingly wide term, and although many engineers might be content to seek refuge in it, and sign the certificate in question, others have adopted the more statesmanlike attitude that the question does not arise at all on a question of audit, and that the Board of Trade auditor is exceeding his powers in demanding such a certificate. In many quarters, therefore, the request has been simply refused, and it is certainly doubtful whether the Board of Trade have power to compel the certificate to be signed. For any companies who may have adopted the suggestion of the Board of Trade that the shareholders' audit should also be utilised for the Board of Trade audit, some difficulty may arise, as the auditor might not wish to sign the accounts on behalf of the shareholders, and refuse to do so on behalf of the Board of Trade. But, in those cases where there are distinct and separate audits, the accounts of the company signed by the shareholders' auditor can be placed before the annual meeting and passed, the dividends, if any, distributed, and the progress of the company's undertaking in no way impeded by an objection on the part of the Board of Trade auditor on a purely technical matter. Under the Electric Lighting (Acts) Amendment Bill, when passed, the Board of Trade will have the power to report such a refusal to Parliament, but the subsequent procedure is not defined.

PARLIAMENTARY INTELLIGENCE

PROGRESS OF ELECTRICAL BILLS.—The London County Council Tramways and Improvements Bill was read a third time and passed in the House of Lords on Wednesday last week. The Holywood Tramways Bill was read a third time and passed in the House of Lords last week.

The South-Western and Isle of Wight Junction Railway Bill was read a third time in the House of Commons on Thursday.

The Bury Corporation Bill was read a third time in the House of Commons on Tuesday.

In the House of Commons on Monday, the Gateshead & District Tramways Bill and the West Kent Electric Power Bill were read a third time.

COLINTON TRAMWAYS.—A public inquiry under the Private Legislation Procedure (Scotland) Act was held in Edinburgh last week, concerning the Colinton tramways. The total length of electric tramway proposed is about two miles, and it is proposed to incorporate a company for continuing the existing line in Edinburgh to Craiglockhart past the side of the proposed cavalry barracks at Redford, on to Colinton, linking on to the junction at Slateford Road with the authorised line which is intended to be formed up to that point by the city of Edinburgh. There was some opposition, but eventually the preamble was found proved. The War Office will contribute towards the construction of the tramways, in return for which they are to have certain rights over the lines in connection with the construction of the proposed cavalry barracks. The estimated cost of construction is £21,000.

Wireless Telegraphy.—On the 9th July, the necessary material for the wireless station was landed at Kingston, Jamaica, and Mr. Marchant, representing the Lepel Wireless Syndicate, Ltd., is now in the island to superintend the erection of the station, which will have a range of 300 miles by night and 200 miles by day. Great interest is being manifested in Jamaica in the new station, and some of the steamship companies trading in the Caribbean are having their steamers fitted so as to be able to get into touch with the island as soon as possible. Most of the vessels in the West Indies are fitted with the De Forest system.

According to the *New York Herald*, experiments have been made recently with a small dirigible balloon which was sent out a distance of one mile and a quarter over the ocean from Sandy Hook, and its movements controlled by Hertzian waves by manipulation of a keyboard on the beach.

THE THORNE BAKER SYSTEM OF PHOTO-TELEGRAPHY

As the result of experimental work extending over a period of two years, Mr. T. Thorne Baker, Manager of the *Daily Mirror* photo-telegraphic department, has made a number of improvements on the existing methods of photo-telegraphy, or the electrical transmission of half-tone and other illustrations, and has embodied all the new features in an apparatus to which he has given the name of the "Telectrograph." A complete set of this apparatus can be seen at work in the *Daily Mirror* Pavilion at the Exhibition at Shepherd's Bush, and another set is, we understand, being used daily for the transmission of photographs over a telephone line from Manchester to London for insertion in the "north-country" edition of the *Daily Mirror*. Illustrations sent on this system are not often published in the London edition, as the original photographs can be sent up by train in time for this edition. Whereas the time elapsing between the dispatch of the photograph and its reception in the engraving department, when sent by rail, is about five to six hours, the corresponding time when electric transmission is employed is said to be only one hour, the actual transmission taking six to seven minutes. Arrangements are now being made for the practical use of the system between London and Paris.

The three most important features of the Thorne Baker system, and the subjects of the various patents covering the system, are the flush-surface transmission negative, the electrolytic receiver, and the method of obtaining clear and accurate transmission of the electric impulses. Each of these features will be fully dealt with in the following description of the system.

The illustration or photograph to be transmitted is photographed through a single-line screen with 75 rules to the inch, on to a fairly thick sheet of lead foil which has been given a thin coating of fish-glue sensitised with bichromate of potash. After developing and fixing, the light portions of the illustration are represented by the films of fish-glue, and the dark portions by the bare lead, the fish-glue not exposed to the light being washed away in the usual way. As the photograph is taken through a single-line screen, the lead surfaces exposed are divided up into series of broken lines of varying width. This variation in width is due to an optical phenomenon, the widest parts of the lines corresponding to the darkest portions of the illustration. In order to give this negative a flush surface, it is placed between two steel plates and subjected to hydraulic pressure, so that a perfectly flat surface of gelatine with the image and shading inlaid, as it were, in lead is obtained. The lead foil is then wrapped round the drum of the transmitting apparatus. This drum is driven electrically at a speed of one revolution every two seconds, or 30 revs. per min., and the contact, shown at *B* in the diagram of Fig. 1, is moved along in a direction parallel to the axis of the drum by means of a nut on an extension of the shaft of the drum, the shaft being threaded 75 lines to the inch. The pointer thus travels vertically down the picture 75 times every inch, crossing the horizontal lead lines (also 75 to the inch), and making and breaking circuit intermittently, the periods of contact being determined by the width of the lines. As shown at *J* in Fig. 1, a variable capacity condenser is placed across the pointer and the drum to prevent sparking.

At the receiving end is a similar drum and pointer. This drum is rotated nearly synchronously with the transmitting drum, and the pointer *M* always occupies a position on the paper wrapped round the drum corresponding to that of the pointer *B* on the drum *A*. The receiving paper sheet is treated with certain chemicals so that the passage of the current, which is very minute (about $\frac{1}{2}$ milli-ampere), causes a permanent black dis-

Digitized by Google

coloration by an electrolytic action. Certain deliquescent salts are also added in order to keep the paper moist and conductive by constant absorption of atmospheric moisture. The operation of the apparatus will now be clear from an inspection of Fig. 1, as with the switches in the positions indicated there is a complete circuit, including a 30-volt battery. When contact is made between lead and pointer at *B*, a black mark is made on the paper at *M*, and in this way the whole picture is reproduced on the receiving drum.

The two drums are run by continuous-current motors

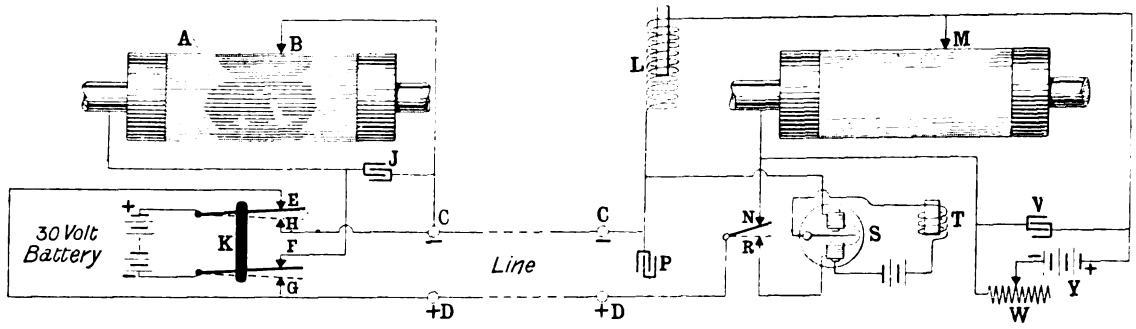

Fig. 1.—Diagram of Connections of Thorne Baker System of Photo-telegraphy.

which have slip-rings connected to two points in the armature windings. Contact is made in each case between the slip-rings and a sensitive frequency-meter of the resonating tongue pattern, which allows of very accurate speed adjustment. The speeds are such that the receiving drum rotates at a speed about 2 per cent. higher than that of the transmitting drum in order that a revolution of the former may be completed just before that of the latter, and the next revolution commenced simultaneously by both drums. The distortion consequent upon this difference in speed is distributed over the whole vertical length of the picture, and is not noticeable. Simultaneous starting is effected as follows: When the receiving drum has completed a revolution, it is stopped automatically, and the contact at *N* is broken, while that at *R* is closed. Immediately after this the transmitting drum completes the revolution, and a cam on the drum moves the switch *K* into the downward direction, so that a current impulse in the opposite direction to that of the normal is sent along the line. This, as the contact at *R* is closed, operates the relay *S*, which, in turn, causes the magnet *T* to be energised to close the contact *N*, and to release the receiving drum, which thus starts the next revolution simultaneously with the transmitting drum.

Lastly, we have the methods of ensuring clear and accurate transmission of the impulses to describe. The pressing of the lead negative, so that a flush surface is obtained, effectually prevents the chattering of the pointer, and enables a higher speed to be obtained than with previous systems, but there is still the difficulty of the inductance and capacity of the line to be overcome. Unless corrected, the effect of these is to fill up the gaps between the impulses, but if properly controlled, the impulses can be transmitted clear and accurate to the receiving apparatus. A variable capacity, *P*, is shunted across the line at the receiving end, and a variable inductance, *L*, is inserted in series in the receiving circuit. These are adjusted to suit the line constants.

By means of the battery *Y*, a constant current is kept flowing between the pointer *M* and the drum in a direction opposite to that of the working current. This current produces no electrolytic action, but tends to balance or counteract the oscillatory currents produced in the cable. A variable resistance, *W*, enables the operator to adjust the value of this current. As in the case of the transmitter, a capacity, *V*, is connected between the drum and the pointer to prevent sparking. It may be mentioned that although the speed was given as 30 revs. per min., we are informed that successful transmissions have been made at four times that speed. With regard to the density of the screen, 75 lines per inch is about the limit for the negative, but this is closer than is necessary for newspaper work, the screen of the *Daily Mirror* blocks being only 55 to the inch.

The accompanying photograph is a portrait of Mr. Thorne Baker himself, exactly as received on the prepared paper sheet of the "Telectrograph" receiver. This was transmitted over an artificial line of 4,000 ohms resistance, with a small experimental equipment with small drums, the actual size being 4¼ in. by 2⅝ in. With large drums, enabling a large reduction to be made, we are informed that very much better results can be obtained.

Mr. Thorne Baker has also developed a system of wireless photo-telegraphy on the same principles, with which, we are informed, the above drum speed of 30 revs. per min. is easily obtained. In this system, the impulses generated by the transmitting apparatus

Fig. 2.—Portrait of Mr. T. Thorne Baker, as received over an Artificial Line with the "Telectrograph."

operate the spark coil of an ordinary wireless set. At the receiver end, the relay in series with the coherer performs the decohering, and also operates a second relay, the local circuit of which contains the 30-volt battery necessary for the electrolytic recording of the impulses. A complete equipment for wireless photo-telegraphy is also on view in the *Daily Mirror* Pavilion at the Exhibition.

Electric Traction on the London, Brighton & South Coast Railway.—The work of equipping the suburban section of the London, Brighton & South Coast Railway from Victoria to London Bridge through Peckham Rye, &c., is now sufficiently advanced for the running of experimental trains during this month and September and the commencement of a full service on October 1st.

Digitized by Google

ELECTRICAL DRIVING IN TEXTILE FACTORIES

AMONG the Papers read at the annual meeting of the Institution of Mechanical Engineers at Liverpool. last week, was one by Mr. H. W. Wilson, on "The Electrical Operation of Textile Factories." At the outset, the author pointed out the necessity to recognise the difference of conditions in every case, which made it difficult to lay down a list of advantages which will apply with equal force to all cases. Stated briefly, however, the main advantage claimed by the advocates of the electric drive and generally admitted by the owners of electrically-driven textile factories is that electrical driving permits of an improvement in the quantity and quality of the output of practically all textile machines. The importance of this point can hardly be exaggerated. If it is once admitted that the claim of the electric drive's advocates in this respect is substantially true, the question of capital cost of equipment and running cost sink into relative insignificance.

To amplify the claims put forward by those in favour of electrical driving, they may in tabular form be stated as follows :— (1) The mill- and engine-house can be placed each in its most convenient position without regard to their relative situations. (2) The internal arrangements of the mill as regards shafting, gearing, belt and rope drives, &c., are much simplified, and the cost reduced. The flexibility as to extensions is, of course, obvious. (3) The grouping of the machines is much less arbitrary than in an ordinary mill, as the motors and light shafting required can be placed where most convenient. (4) The reduction of the chance of a breakdown which would stop the whole mill. (5) The ease with which sections of the machinery can be either stopped or run overtime (where conditions permit) without waste of power. (6) The reduction in the maintenance and depreciation charges. (7) The reduction in the capital cost per loom or per spindle of the whole factory when once a given size is exceeded. This is partly due to reduction in the weight and cost of the buildings. (8) The possibility of obtaining records of the work done in the different sections of the factory, otherwise impossible, and the keeping of a constant check upon them. (9) The greater steadiness of drive which can be obtained with a consequent permissible higher average speed and increased output.

This last claim is by far the most important one. It has been proved in many cases that electrically-driven spindles can be run at a higher average speed, on the same counts, than mechanically-driven ones, with a corresponding higher production, owing to the fact that the electrically-driven spindles run more steadily. Except in cases where a varying speed in arranged for to suit special conditions, an absolutely constant speed is most desirable. Slight variations in speed above that corresponding to the maximum safe tension breaks the threads.

In an electrically-driven factory properly laid out, the speed of every machine should correspond directly with the speed of the prime mover, and, given satisfactory regulation on the engine, every producing machine can be speeded up to its safe maximum and kept there. With even the best rope transmissions it has been found in a number of cases that the speed of the machines closest to the driving point is steadier and higher than that of the machines furthest away. In one fairly well-known case in Lancashire, with two mills under the same management and of about the same size and working under the same general conditions, the results obtained from the electrically-driven factory have been superior to those from the mechanically-driven one—to such a marked extent that the output of the electrically-driven mill fetched a better price than that from the other factory, to the extent of about 2½ per cent. It is difficult to get statistics concerning the improvement in output and quality, but it may be taken as a conservative estimate that the increase in production is on the average at least 5 per cent.

Considering Lancashire practice, it may be advisable to point out that the cotton spinners and weavers state their costs at so much per pound of yarn or cloth produced. In the case of a spinning mill on most classes of counts, it may be taken that the margin over the price of raw cotton, out of which the manufacturer has to pay all his costs and make his profit, is something like 3d. to 3¾d. per lb.

Assuming a price of 4d. per lb., therefore, the selling price of the yarn would be, say, 7½d. A considerable portion of this 3½d. is made up of the piecework price per lb. paid to the operatives, and it would not be easy to get any modification of this price. What may be taken as the standing charges of the mill—that is, the amount required to cover rent, rates, taxes, insurance, salaries, day labour, and cost of power—is but a comparatively small percentage of the cost of the finished article, and it would therefore take a considerable increase in output to make any considerable difference in the total costs per pound. Assuming, however, that these fixed charges amount to 12 per cent. of the total costs, which is a fairly average figure, then an increase in output of 5 per cent. would mean a reduction in cost per lb. on the whole output of 0·6 per cent. In a modern spinning mill the total power costs do not amount to more than 2½ per cent. to 3 per cent. of the total expenses, and an increase of 10 per cent. in the cost of power would only mean an addition of 0·25 per cent. to the cost per lb. of production. It will be seen, therefore, that even allowing for a considerable increase in the cost of power, which personally the author does not admit, there is a margin of 0·35 per cent. extra profit on the whole turnover, which means a considerable amount in a year.

Admitting for the sake of argument the approximate correctness of these figures, the opponent of the electric drive would advance the objection of increased capital cost caused by the installation of an electrical transmission system, but it may be said that in a new spinning factory below 80,000 mill spindles the mechanical transmission system is the cheaper, between 80,000 and 100,000 the costs are about equal, and above 100,000 the electrical system is the cheaper.

In the case of an old factory requiring re-equipment, it frequently happens that owing to the inconvenient arrangement of the existing buildings the electric drive offers distinct advantages both as regards initial capital outlay and efficiency. Cases have come before the author where the conversion has resulted in a reduction of 20 per cent. of the power consumption.

The intermediate case, however, of a fairly modern factory with a good mechanical transmission system requiring extensions above the capacity of the engine is a very interesting and promising one. Under such circumstances as these the use of the exhaust steam turbine has many advantages, and this almost of necessity involves either wholly or partially the electrical driving of the factory.

To take a concrete case now under consideration. A spinning mill mechanically driven but electrically lighted has a main engine of the compound vertical type developing 1,000 i.h.p. with a steam consumption of about 13 lb. per i.h.p.-hour. The lighting dynamos are driven by the main engine, and in the winter when fully loaded require a trifle over 100 h.p. It is required to make some extensions in the factory involving an additional load of about 200 h.p. It was first suggested that a generating set of 150 kw. should be installed at once, and later on a second set of the same capacity when other extensions became necessary. The first set would supply the lighting and also about 100 h.p. of motors in the preparation section, and thus relieve the main engine.

A small set such as this would use at least 16 lb. of steam per i.h.p.-hour, and it has since been suggested that an exhaust steam turbine might be a better solution of the difficulty. As plenty of condensing water is available the question was investigated, and it has been found possible to alter slightly the valve-setting of the main engine, obtain about 850 i.h.p. from it non-condensing and 500 i.h.p. from an exhaust steam turbine utilising the steam from the engine. In this manner it would be possible to obtain some 1,350 i.h.p. for a steam consumption of about 10·5 lb. per i.h.p.-hour. The saving in fuel over the other arrangement suggested is approximately 30 per cent.

There are, however, several features in this case which require to be specially met, and the most important and obvious of these is the fact that the load on the turbine generator is to be a variable one, at all events as far as regards the lighting. This is a feature of difficulty, inasmuch as the load on the main engine is fairly constant and the amount of steam passed by it fairly regular. In order to meet the conditions, it is necessary either to use a portion of the steam from the main engine for other purposes at times of light load on the turbine, or else to make such an arrangement as will permit of the variation in load affecting both engine and turbine in the same proportions, and thus automatically regulating the supply of steam to the combined machines. The simplest method of doing this is to rope-drive a small generator of, say, 100 kw. capacity from the engine, and to run this generator in parallel with the turbo-generator. This involves again the driving of a larger portion of the mill electrically than was originally intended, but the large fuel economy justifies this apart altogether from every other consideration.

A question which is frequently argued with great vigour is the advisability or otherwise of a textile factory taking its supply of power from an outside source. This means, of course, the price at which it pays a manufacturing concern to buy energy rather than to produce it itself. The result of the author's observations is that a Lancashire factory of, say, 1,500 i.h.p. capacity can produce energy at, say, 0·2d. per i.h.p.-hour, or

Digitized by Google

0·3d. per kw.-hour, allowing for interest and depreciation. This is on a basis of being able to purchase good slack with a calorific value of 11,000 B.Th.U. at 8s. per ton delivered. It has been found generally practicable to induce fairly large factories to purchase power at about 0·4d. per unit net, the power being metered on the low-tension side of the mill switchboard before reaching the motors.

The main differences of opinion among engineers designing the lay-out of electrically-equipped mills arise over the questions of group or individual driving. The larger and the fewer the motors in a mill the smaller is the capital outlay; but at the same time the less the special advantages of electrical driving are felt. The more nearly the ideal of a motor to every machine can be approached the better the actual results, but the higher the capital outlay and generally the running cost. The author's personal feeling is in favour of the individual driving of ring spinning-frames, and the group driving of all other machines, but keeping the groups fairly small.

A point needing attention is the heating effect of the motors. In a ring spinning-room, for example, with a large number of small motors directly coupled to single machines, the total amount of heat given off from the motors may be sufficient to raise the room temperature considerably. It is now the best practice to build these motors with hollow frames, and to bring cooling air from some external source round the frames, thus preventing the discharge of heat to the room.

The Paper concludes with some tables of the horse-power required by various classes of machines in textile factories.

DISCUSSION.

The discussion was opened by Mr. Mark Sutton (Rio de Janeiro), who said that his firm had already installed two mills with electrical driving, one with individual drive, especially for machines that consumed something like 5 h.p., but his difficulty up to the present was with regard to employing a motor of 5 h.p. to do the work of 5 h.p. Now, in the majority of cases, the makers advised putting in a motor of, say, 8 h.p., to drive spindle frames for instance, whereas, according to the tests, one only required from 4 to 5 h.p. In the first mill they installed group driving. In thinking over the matter, he arranged a plan for driving the machines with a motor working more or less at its most efficient power, and this had given excellent results. The motors had been running now about seven months, and they had had no trouble whatever with them, and they had done very well. He claimed certain advantages with those motors through not having to stop them. They were started up in the morning, and the belts shifted off the loose pulley on to the fast pulley. They were driven by belts 6 ft. from centre to centre, but there was very little slip.

Mr. A. Saxon (Manchester) remarked that 4d. per lb. was mentioned in the Paper, but to-day it was at least 6½d., so that if there was a 50 per cent. error in one item alone, it affected the other part of the argument. He was a believer in electrical driving, but not a believer in applying electricity indiscriminately. With regard to comparison in the Paper of two mills, one electrically driven, the author did not explain that one mill was built in about 1855, and the other mill about 1905, but went on to make a comparison of the electrical driving of one mill and the mechanical driving of the other, and showed an increase of 2½ per cent. in production. He should think there would be. He understood the mills mentioned were situated at Pendlebury. The author had avoided names in his Paper, but if they were to have comparisons, let them be of the best and most up-to-date steam and electrically-driven mills, and then the comparison would be made on fair lines. The author had referred to the Bannerman Mills, Manchester. Now, his firm had had to do with the old engines at that mill for perhaps as far back as forty years, and if the mill people had had some new engines installed, there would have been considerable improvement in their working. The Manchester Association of Engineers recently visited two cotton mills where his firm's engines were installed, and the Moscrop recorders on those engines would show that electrical driving could not possibly have improved on them. He had the opportunity recently of going through the Stuart Street Power Station of the Manchester Corporation, from where the Bannerman Mills were obtaining their supply of energy, and he noticed that there was a speed recorder installed in the station. He inquired the purpose of the recorder, and was informed that it was installed in consequence of complaints being received of the turning from the mill people, and that was the very mill that the author referred to.

Mr. F. A. Cortez Leigh said that he had been rather amused by Mr. Saxon's remarks, as he happened to be the electrical adviser for Mr. Macara, of the Bannerman Mills Co., and therefore knew the actual conditions of the case. It was quite true that in connection with these mills a comparison was made between the electrical drive and the mechanical drive, but this comparison was made with an up-to-date steam engine, and after Mr. Macara had considered very carefully all the points a decision was come to in favour of the electrical drive; it was so much cheaper, and more reliable. He (Mr. Leigh) came on the scene after Mr. Macara had compared the prices for both the engines, boilers, &c., and also the electrical drive. As for the power, the question was considered from the point of view of generating their own current, or taking this from the Corporation mains, and the mill people decided on the latter course, and which they were doing at the present time.

The Author, in reply, said that he was very much interested in what Mr. Sutton had said, particularly about the individual drive. With regard to the question of the power developed by motors, he thought it might possibly be a fact that cotton mill textile machinists as a whole were inclined, when they had estimated the power required by a number of machines, to take this as one figure, and they probably say that a group of forty ring spinning frames would take 200 or 240 h.p., and they did that simply because they knew that a certain percentage of those frames would be stopped, and the average thus obtained would, of course, be not quite correct for the power that an individual frame would require when it was running at full load. Mr. Saxon was quite correct with regard to the addresses of the mills referred to in the Paper, but with regard to his statement that one mill was built in 1855, that was only correct as far as the building itself was concerned, but this mill was re-equipped about twelve or thirteen years ago. With regard to the question of the price of cotton, that was such a variable quantity that it was difficult to tie one's self down to any particular figure, but he had taken 4d. to 5d. as being a fair average price year in and year out, and the rise in price at the present time was really in favour of his argument instead of against it.

CRYSTAL PALACE SCHOOL OF ENGINEERING

On Thursday last, the workshops and drawing offices of the above Institution, which was founded as long ago as 1872, were open to inspection on the occasion of the presentation of the certificates to successful students of the past term. Courses of lectures in civil, mechanical, and electrical engineering are given at the schools, and the students are also taught pattern-making and do practical work in the fitting and smith's shop. Some examples of the work done in the pattern shop, and a collection of the term's work in the different drawing offices were on view on Thursday, and reflected great credit on both staff and students. Mr. Maurice Wilson, the vice-principal, read the reports of the examiners, who, according to the usual custom, were three engineers not associated with the school. Mr. R. F. Housman, A.M.I.M.E., Mr. Wood Hill, M.I.C.E., and Mr. Percy Speedy, A.M.I.E.E., were the examiners in the three departments for the past term, and all submitted most favourable reports. Colonel Sir Edward Raban, K.C.B., Director of Works to the Admiralty, then addressed the students, congratulating them on the reports of the examiners. After advising the students to study men and to learn to have a right appreciation of the men both above and below them, he emphasised the importance of business aptitude, accuracy, and clearness of expression in speech and writing, without which engineering skill availed little. Colonel Raban also referred to the preparation of reports on engineering schemes, pointing out that the question of cost should be constantly before the engineer, who always had to sacrifice engineering perfection in order that the scheme might be practicable from a commercial standpoint. An engineer should, he said, always be prepared to meet emergencies. Finally, he urged the students to aid in the advance of the nation by becoming good citizens and taking an intelligent interest in public works. After Colonel Raban had presented the certificates to the students, the Principal (Mr. J. W. Wilson) spoke a few words of encouragement to those leaving the school, and the proceedings terminated with a vote of thanks to Colonel Raban.

The "Electron."—The July issue of this magazine, the official organ of the Siemens' Stafford Institute, is the first number of the second volume, and contains a tribute to Mr. J. F. Crowley, who has resigned the editorship of the magazine. Among the articles is a fully illustrated description of the power installation in the weaving shed at the jute spinning mills of Messrs. W. Blutchen & Sons, of Vetschau, and Mr. S. K. Ferrier gives some interesting notes on weaving, intended for those interested in the application of electric driving to this industry, but not familiar with the processes involved. This number also includes the first instalment of an article by Dr. M. Kloss on the starting torque of squirrel-cage induction motors, in which the various relations are deduced with the aid of the Heyland diagram. The origin of Siemens is sketched by Mr. F. E. Read, who concludes with a useful summary of the organisation of Messrs. Siemens-Schuckert and Messrs. Siemens & Halske, and C. W. Miller describes the growth of the Siemens Cottage Estate at Stafford. Some notes on the athletic sections of the Institute conclude this number. An interesting feature of the magazine is that portion of the editorial section containing notes on the work and progress of present and past members of the Siemens staff both at home and abroad.

NEW TARIFFS IN MARYLEBONE

MR. A. H. SEABROOK, the general manager of the St. Marylebone Electricity Department, submitted a report to the Electric Supply Committee towards the end of last month, relating to the charges made for electrical energy, and this, after being approved by the Committee, was discussed and passed by the Council at their meeting on July 29th. The report recommended that, as an alternative to the present maximum demand system at 8d. and 1d., the consumer should be charged a rental for his maximum demand, plus 1d. per unit consumed.

For large consumers (from 50 kw. maximum demand or power required, and upwards) the charges are as follows :—

Power required.	Minimum Fixed Annual Charge.
200 kw.	£900 0 0
175 kw.	853 2 6
150 kw.	787 10 0
125 kw.	703 2 6
100 kw.	600 0 0
75 kw.	487 10 0
50 kw.	350 0 0

Additional kw.'s *pro rata* per kw. or part thereof per annum; and 1d. per unit for all units consumed.

Terms: Ten years' contract and exclusive use of electricity for lighting and power (motors), the "kw. charge" being payable annually in advance.

For medium-size consumers (between 50 and 20 kw. maximum demand) the charges are :—

Power required.	Minimum Fixed Annual Charge.
45 kw.	£336 5 0
40 kw.	300 0 0
35 kw.	271 5 0
30 kw.	240 0 0
25 kw.	209 7 6
20 kw.	180 0 0

Additional kw.'s *pro rata* per kw. or part thereof per annum; and 1d. per unit for all units consumed.

Terms: Five years' contract and exclusive use of electricity for lighting and power (motors), the "kw. charge" being payable annually in advance as before.

With regard to these two classes of consumers, Mr. Seabrook states that the above are minimum terms, and that it is not an inflexible tariff. For instance, if it is inconvenient for a consumer to pay annually in advance, or to enter into a long period contract, the charge per kw. will be accordingly increased, taking into consideration the directions in which the consumer cannot meet the conditions.

For small consumers (below 20 kw. maximum demand) the charges are, for lighting only :—

Power required.	Minimum Fixed Annual Charge.
18 kw.	£166 10 0
15 kw.	150 0 0
12 kw.	126 0 0
10 kw.	110 0 0
8 kw.	92 8 0

Additional kw.'s *pro rata* per kw. or part thereof per annum; and 1d. per unit for all units consumed.

7 kw.	£82 5 0
6 kw.	72 0 0
5 kw.	62 10 0
4 kw.	51 0 0

Additional ¼ kw.'s *pro rata* per kw. per annum; and 1d. per unit for all units consumed.

3½ kw.	£45 1 3
3 kw.	39 0 0
2½ kw.	32 16 3
2 kw.	26 10 0

Additional 1-10th kw.'s *pro rata* per kw. per annum; and 1d. per unit for all units consumed.

1¾ kw.	£24 10 0
1 kw.	14 0 0
¾ kw.	10 10 0
½ kw.	7 0 0
¼ kw.	3 10 0
1-10th kw.	1 8 0

Additional 1-20th kw.'s *pro rata* per kw. per annum; and 1d. per unit for all units consumed.

The charges for all units consumed to be paid weekly, monthly, or quarterly, as may be required. The annual charge would be paid annually in advance and be based on the consumer's "power required" for the previous year. In the case of new consumers, whose "power required" is not ascertained, the "annual charge" for the first year is to be assessed by the general manager, and he is to have power during any year to re-assess the annual charge for that year as circumstances may warrant.

No alternative to the existing 2d. and 1d. maximum demand system for small consumers using motors, *i.e.*, factories, &c., is to be given at present, but the following scale of charges for heating, cooking, and other uses, is to be adopted :—

Power required.	Fixed Annual Charge.
¼ kw.	£0 5 0
½ kw.	0 10 0
¾ kw.	0 15 0
1 kw.	1 0 0
2 kw.	1 10 0
3 kw.	1 15 0
4 kw.	2 0 0
5 kw. and upwards	2 2 0

And 1d. for all units consumed, payable weekly, monthly, or quarterly, as the Council may require.

In his concluding remarks, Mr. Seabrook points out that under the new tariff only one integrating meter and one "maximum demand" indicator are required, duplicate wiring for heating circuits being rendered unnecessary, as the "maximum power required" for heating can be estimated. The tariff is to be taken into use at once in the case of large and medium consumers; but in the case of small consumers from December 31st next.

Mr. Seabrook suggests that this tariff be named the "telephone system" of charging, as it is analogous to the ordinary message rate system used by the Post Office and the National Telephone Co. It will be seen that the system is similar to that adopted by practically all the electric power companies; some of these charge a fixed annual rental per kw. of maximum demand (plus a charge per unit), but others decrease the charge per kw. as the maximum load increases, just as Mr. Seabrook proposes to do.

THE INSTITUTION OF ELECTRICAL ENGINEERS' NEW BUILDING

AT a special general meeting of members, associate members, and associates of the Institution of Electrical Engineers on Thursday, the following two resolutions were passed :—

(1) "That the action of the Council in borrowing the sum of £26.000 from the Economic Life Assurance Society on the security of the leasehold property of the Institution on the Thames Embankment on the terms of the indenture of mortgage dated June 1st, 1909, a copy of which is now produced to the meeting, be and is hereby authorised and confirmed."

(2) "That an expenditure of a sum not exceeding £20,000 on structural alterations, furniture, and fittings in connection with the Institution building be sanctioned and approved, and that the Council be authorised to make such financial arrangements (including the borrowing of money on the security of the Institution building, and of the Institution property in Tothill Street), as the Council may consider necessary for the above purpose."

Before putting these resolutions, Mr. W. M. Mordey, the President, made the following statement :—

We have now reached a very important stage in connection with our new building on the Victoria Embankment. On June 30th last year, at a special general meeting, authority was given for the purchase of the property for a sum of £50,000. This purchase was duly completed on June 1st this year, the purchase money being provided as follows :—From the accumulated funds of the Institution, £24.000; from a mortgage on the building, £26,000; total, £50,000.

Ever since the meeting of June 30th last year, the Council have been engaged on the consideration of various schemes for adapting the building to the purposes of the Institution, and they have finally decided that it will be in the best interests of the Institution to enlarge and improve the entrance hall, and to rebuild the theatre completely. Plans prepared by our architect, Mr. Percy Adams, have been considered, and finally specifications have been issued, and tenders obtained for the work. The result is that an expenditure estimated at £18,000 is necessary to cover these alterations in the building, and the equipment and furnishing of the large library on the first floor, and of the parts of the building to be occupied by the institution, including also the cost of a lift, and various other matters necessary to adapt the whole of the other parts of the building to the requirements of our tenants, the Colleges of Physicians and Surgeons. The new theatre will be a very handsome one, appreciably larger than that of the Institution of Civil Engineers, in which we have for so long had the great

Digitized by Google

privilege of holding our meetings. The modified entrance hall will provide a very attractive and convenient means of access to the theatre, library, offices, and public rooms.

The funds of the Institution would be sufficient for the purpose of the required expenditure if we sold the Tothill Street site, at the price we gave for it, viz., £17,500, a price which we are advised is a low one. It is believed that when the time is more favourable we shall be able to dispose of the site at a profit.

Meantime we have arranged for a mortgage on the Tothill Street property, of £11,500, and have securities available amounting to £4,000, a total of £15,500. As already explained, the estimated expenditure is about £18,000, and, adding £2,000 for contingencies and margin, we require a total of £20,000.

We are therefore short to the extent of about £4,500. The sale of Tothill Street at cost price would, after paying off the mortgage, yield £6,000. To meet this expenditure of £4,500, and to justify the Council in putting before the members a recommendation to proceed with the proposed alterations, the past and present members of the Council have guaranteed the difference between the assets and the requirements, on the understanding that if they are called upon to make any payments under this guarantee, they are to be repaid out of the funds of the Institution when available, either as a result of the sale of the Tothill Street property, or from contributions to the Building Fund, or otherwise.

ELECTRIC MOTORS v. GAS ENGINES

A CORRESPONDENT has written to us with reference to the article entitled "Selling Gas Engines" on page 666 of last week's ELECTRICAL ENGINEERING, relating his experiences of the relative costs of gas engines and electric motors for driving a small works.

Our correspondent, who is a brass founder in Aberdeen, writes:—

"Although I am not an electrician, I take your paper regularly, and I find it to my advantage to do so, rather strangely in a greater degree than from any other trade paper I have ever had.

"In the hope, therefore, that it may interest you a little, I send you my experience of the relative costs of using gas engines and motors; nor does the saving shown in the case of the motors by any means indicate the full measure of my gain by the change."

He then speaks of the advantages both to his business and his own health experienced by the elimination of noise and smell since the adoption of the electric drive, and proceeds to give the following figures for the comparative cost of gas and current:—

Gas Engine.

	£	s.	d.
For year 1899	21	11	2
,, ,, 1900	25	3	5
,, ,, 1901	25	8	7
,, ,, 1902	25	18	2
,, ,, 1903	24	4	2

Electric Motors.

,, ,, 1904	11	13	8
,, ,, 1905	10	13	11
,, ,, 1906	10	13	11
,, ,, 1907	12	5	10
,, ,, 1908	10	16	4

Gas and current were both taken from the Corporation mains; for the year 1907 the figure includes current used for electric welding, and that for 1908 a small office radiator. The extra expenses for waste, oil, repairs, and attention for the gas engine were considerable, and the engine was eventually sold for old iron. The two motors, out of which more work is obtained than was from the gas engine, "seem better than ever, in spite of careless usage, with only a trifling expense for new brushes."

Telegraph Traffic.—There are no interruptions to submarine cables to report. The land lines between Bagdad and Bassorah, and between Hanekin and Teheran, have been restored to working order. Interruptions have, of course, occurred to telegraphs in Spain due to the various riots, but these, no doubt, will soon be put right. The Dakar-Covakry, Tangier-Cadiz, and Tourane-Amoy cables have been down since May 12th and 19th and June 17th last respectively, and have not yet been restored to working order. Restrictions on telegrams to Central and some parts of South America still exist, and it is probable that this state of affairs will continue for some time.

TELEGRAPHS OF THE WORLD

IN view of the prominence recently given to telegraphic matters, and the important part this means of communication plays in our daily life, an examination has been made of official returns for the year 1907, and the following approximate statement has been prepared of the receipts and the number of all kinds of telegraph messages dealt with. The figures so far are only available for the countries mentioned, but when it is considered that such countries as the United States of North America, Canada, Brazil, Portugal, Central and South America, West Indies, parts of Africa, China, &c., &c., are not included, some idea may be obtained of the enormous use made of the telegraph systems of the world. Revenue obtained by telegraph and cable companies would also not be included in the receipt figures.

Country.	Receipts. £	Number of telegrams dealt with.
Argentine Republic	382,159	7,082,682
Austria	582,325	19,633,094
Belgium	227,372	7,839,328
British India	928,679	14,851,286
Bosnia and Herzegovina	22,290	679,946
Bulgaria	52,521	1,700,223
Cape of Good Hope	220,539	2,683,406
Chili	256,920	2,207,769
Commonwealth of Australia and New Zealand	997,446	22,763,581
Denmark	92,511	2,985,884
Dutch India	84,141	966,750
Egypt	118,564	5,948,388
France, Corsica, and Algeria	1,653,169	62,049,366
French Indo-China	22,609	1,194,030
Germany	1,751,992	54,678,383
Great Britain	3,125,654	90,133,000
Greece	76,914	1,607,867
Holland	191,071	6,352,049
Hungary	280,864	10,708,236
Iceland	1,201	19,516
Italy	764,742	16,137,187
Japan and Corea	763,380	29,410,045
Luxemburg	3,592	209,225
Natal	44,163	549,470
New Caledonia	2,568	32,968
Norway	252,416	2,762,100
Orange River Colony	21,306	429,683
Portuguese Colonies, Angola, Mozambique, India	9,333	240,899
Roumania	153,236	3,192,664
Russia	3,874,619	30,025,482
Servia	23,016	830,317
Spain	357,489	5,606,279
Sweden	127,483	3,918,801
Switzerland	146,353	5,106,173
Tunis	22,169	984,776
Total	£17,615,206	415,528,848

The number of telegrams includes in many cases those sent on Government services for which no payment is made, and the receipts contain revenue from all sources, such as charges for registered addresses, &c. From these figures it may be assumed that the value and volume of the world's telegraphic business are about double the figures above given.

Associated Municipal Electrical Engineers (Greater London).—Mr. Albert Gay, Chief Electrical Engineer to the Islington Borough Council, has been appointed President for the year 1909–10.

Mining Institute of Scotland.—The annual excursion of the Mining Institute of Scotland will be made to Lochgelly on Saturday, August 14th. The members will assemble at the Lochgelly Works office at 11 a.m., and will inspect, among other things, the electric power station and sub-station.

Automatic Signalling on the Metropolitan Railway.—It is announced in the *Railway Gazette* that, having found great advantages to accrue from the adoption of automatic signalling on the Inner Circle, the Metropolitan Railway now has it in contemplation to instal this system of signalling also on the Extension Line from Baker Street as far as Neasden, as the train service on that section is now so heavy as to necessitate a quicker method of signalling than the existing manual system.

Theft of Electrical Energy in America.—An employee of the Edison Electric Illuminating Co., of Boston, U.S.A., has been arrested on the charge of unlawfully diverting current for the benefit of certain customers. An elaborate scheme, in the operation of which, it is expected, many other employees are concerned, has been brought to light.

Digitized by Google

THE "LAMP FLASHING" CIRCUIT ON C.B. TELEPHONE EXCHANGES

Method of Clearing a Local Connection when a Subscriber's Line is required for a Trunk Call

By Charles Hughes

In Electrical Engineering of March 18th, a description was given of the National Telephone Co.'s new central battery exchange at Manchester, and mention was made of an innovation in the method of operating the "lamp flashing" circuits on the trunk junction positions. The present article is the outcome of a suggestion made by the Editor that a more detailed description of the system would interest many of his readers.

Before attempting to describe the circuit itself, it will be advisable to run through the operating of a trunk call from the Post Office trunk exchange to the National Telephone Co.'s exchange. The Post Office operator asks for the required number on an order wire; in the case of a trunk exchange where the junctions are not multipled over the trunk sections, she herself assigns the junction to be used, or where the junctions are multipled over the trunk sections, the junction to be used is assigned by the National operator. The National operator then taps the bush of the required subscriber's multiple jack with the tip of the junction plug to determine whether the line is engaged. If disengaged, the plug is inserted in the jack and the subscriber is rung up by the National operator. If the required subscriber is already engaged on a *trunk* connection, the operator on testing will receive a special engaged test, due to a special tone which is, in all cases where the trunk junctions occupy more than one position, connected to the third conductor of the trunk junction cords (see Fig. 2). The operator hearing this special tone informs the Post Office operator, either verbally, or by means of the busy-back signal, that the required number is already engaged on a trunk connection.

In the event of the number being engaged only on a local connection, the subscriber is to be offered the trunk call. The operator then inserts the plug into the subscriber's jack, throws the listening key into the speaking position, and asks the subscriber if he will accept the call, and if, as usually happens, the subscriber agrees, it is necessary to interrupt the local connection before the trunk connection is made. It is to give the local operator the signal for this purpose that the "lamp flashing" circuit is used, its function being to flash the supervisory lamp in the cord circuit on the "A" position where the subscriber is connected. The "A" operator, on receipt of this signal, takes down the connection, and the trunk junction operator is informed by the lighting of a lamp in connection with the "lamp flashing" cord at her keyboard that the connection has been cleared, and that the trunk connection can be made.

In the original arrangements for connecting the "lamp flashing" circuits to the subscriber's line, the operator had to remove the junction plug from the multiple jack, and insert the "lamp flashing" plug. On receipt of the lamp signal indicating that

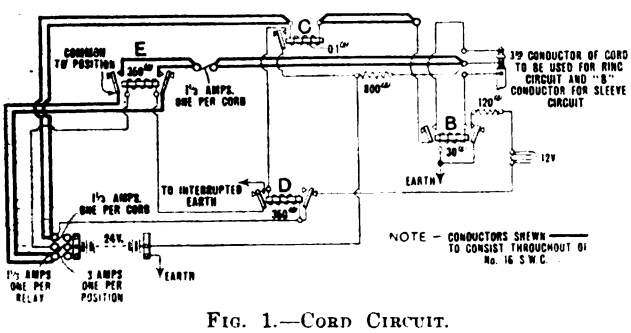

Fig. 1.—Cord Circuit.

the connection had been cleared, she had to withdraw the flashing plug and again insert the junction plug.

This has now been simplified by the insertion of a break jack in each of the trunk junctions at the company's exchange. The insertion of a flashing plug into this jack cuts off the junction circuit, and connects the flashing circuit through the junction cord on to the subscriber's line. The withdrawal of the flashing plug on receipt of the clearing signal leaves the subscriber connected through to the Post Office exchange.

The most stringent conditions under which the flashing circuit (see Fig. 1) has to work are when the exchange battery is at 30 volts, due to charging, and when the required subscriber's line is very short, or, as it is termed, a "zero loop," and he remains at the instrument with his receiver off the hook. Under these conditions, the current passing through the supervisory relay, where the connection is set up, is 220 milliamperes, and as this relay is adjusted to release at 3 milliamperes, it is necessary to reduce the current to this latter figure to allow the relay to fall back and light the supervisory lamp.

A skeleton circuit, showing the actual conditions, when the junction plug is connected to an engaged line, is shown in Fig. 2. Immediately the flashing plug is inserted into the break jack *J*, a current flows through the lamp and relay *A* of the junction and relay *B* of the flashing circuit (Fig. 1). This circuit is in parallel with the third conductor of the local cord and the subscriber's cut-off relay *G*.

Relay *B*, actuating, closes the tip circuit of the cord, which completes a path through relay *C*, and the repeating coil of

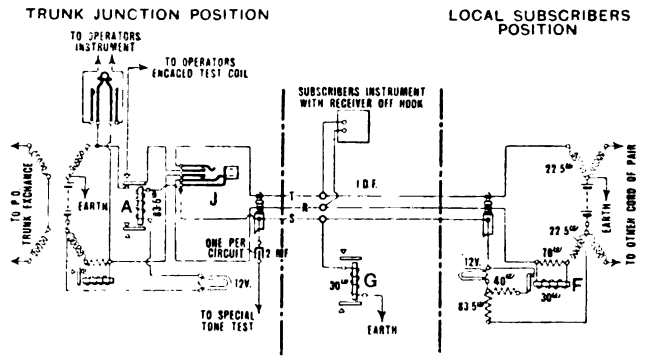

Fig. 2.—Theory Diagram.

the local cord circuit to earth. The closing of this relay operates relay *D*, which disconnects the clearing lamp circuit and brings relay *E* into circuit. This latter relay is operated intermittently by means of an earth connection through one of the interrupters on the exchange ringing machine; this interrupter is designed to operate the relay for 0·6 second, and to break the circuit for 0·9 second.

It will be seen that, although the current flowing through relay *C* to the tip of the cord, and through the repeating coil of the local cord circuit, practically short-circuits the subscriber's loop, there is still sufficient current flowing through the 800-ohm spool, and the supervisory relay *F* to operate the latter, the operating current being 16 m.a. The operation of relay *E* for 0·6 seconds at 0·9 seconds intervals short-circuits relay *F*, and causes it to release and flash the supervisory lamp, relay *F* again operating through the 800-ohm spool and shunting the lamp, when relay *E* falls back.

Immediately the flashing signal is received, the local plug is withdrawn, and this breaks the path to earth through the relay *C* and the repeating coil; the current flowing round the subscriber's loop is not sufficient to retain this relay, which releases and cuts relays *D* and *E* out of circuit. The armature of relay *D* completes the circuit of the flashing cord clearing lamp, and the junction operator withdraws the plug, leaving the subscriber through to the Post Office exchange.

It should be noted that, should the subscriber replace his receiver, either before or after the "lamp flashing" plug is connected to the line, it will not affect the operation of the circuit, also that, on the withdrawal of the local plug the cut-off relay *G* is still operated in parallel with relay *B*, thus preventing the calling lamp from lighting.

The description given applies to all local connections to or from the required subscriber, with the exception of in-coming calls from a distant central battery exchange. The insertion of the flashing plug in this case would not flash the lamp in connection with the C.B. junction plug in the subscriber's multiple jack, but would flash the supervisory lamp in connection with the plug inserted in the junction jack at the distant exchange. The operator withdrawing this plug would give the clear to the C.B. junction operator, who would clear the connection, and give the clear on the flashing cord.

It is, of course, necessary in dealing with such small

Digitized by Google

currents to keep the resistance of the flashing leads as low as possible, and for this reason the leads are made up of two No. 16 S.W.G. wires in parallel. For the same reason, all the flashing cords are reduced to as short a length as possible (4 ft.), and the third conductor of the cord, which is usually connected to the sleeve of the plug, and which is about half the resistance of either of the other coductors, is connected to the ring of the plug.

The tip connection of the cord is taken through the contacts of the relay *B* to prevent the 1½ ampere fuse being blown should the tip of the plug by any means touch the frame of the board, which is permanently connected to earth.

LOCAL NOTES

BRAZIL: *Electric Tramways.*—A British Consular report states that during the year 1908 the electrification of the tramways in Porto Alegre, formerly worked by mules, was completed, the contract for the work having been given to a British firm. The tramways were previously owned by two companies, but the municipality having agreed to give a practically new concession for a term of forty years on condition that change to electric traction was made, an amalgamation was effected, and the two were constituted into a new company called the *Companhia Força e Luz Porto Alegrense*. The capital required was all raised locally, viz., £165,625, in debentures, and a further £62,500 by unsecured loan. An offer made by a London syndicate, the Anglo-South American Public Works Co., Ltd., to purchase the concession and property has been accepted by the requisite majority of the shareholders in general meeting, and as soon as the necessary formalities are completed the transfer will take place. Since the electrification the traffic has steadily increased.

Electric Lighting.—During the year, also, the municipality completed the installation of an electric lighting system principally for the public illumination of the suburbs and parts of the city not lighted by gas. A very limited number of private consumers is also supplied where gas cannot be obtained, but the installation is not large enough to supply electric lighting in a general way.

Water-Power Transmission Plants.—A British Consular report states that although the State of Sao Paulo has been referred to as the cradle of the utilisation of hydraulic power in Brazil for generating electricity, that at present turned to account is but insignificant in comparison with the immense undeveloped resources which the State possesses in the numerous large waterfalls, mostly State property, and to a large extent still unexplored. The principal hydro-electric installations constructed in the State are that of the Sao Paulo Tramway, Light & Power at Parnahyba, with a capacity of 8,000 horse-power, and those of various other companies, viz. :—At Jundiahy, generating 1,000 kilowatts; Sorocaba, generating 1,000 kilowatts; Rio Claro, generating 580 kilowatts; Mococa, generating 500 kilowatts; Piracicaba, generating 450 kilowatts. The important hydro-electric station in course of construction by the Santos Dock Co. at the Itatinga Falls, near to Santos, which should be completed in a year's time, will transmit electrical energy for working the cranes on the quay at Santos and the supply of light and power to that city.

BRIGHTON: *Charge for Tramway Energy.*—After a lengthy debate, the Council have adopted a recommendation of the Electricity Committee that the charge for tramway energy shall be 1·4d. per unit. An amendment that the price should be 1·35d. was rejected. Hitherto the Tramways Committee have paid 1·5d. per unit.

BULAWAYO: *Public Lighting Dispute.*—*South Africa* states that the award of the arbitrator in the case of the municipality of Bulawayo and the Bulawayo Waterworks Co. is in favour of the former. The Waterworks Co. are thereby ordered to install, as originally requested by the municipality, 50 c.p. Osram lamps for the street lighting of Bulawayo by December 31st next. The effect of the change, it is said, will be a saving per year to the town of nearly £2,000.

BURNLEY: *Cost of Service Lines.*—The Electricity Committee have decided to alter their practice as regards the payment of the cost of laying service lines. In future all persons requiring a supply of electricity are to be charged the cost of laying cable in excess of 60 ft., and the cost of laying cable on private ground.

CHINA: *Electric Traction and Lighting.*—A British Consular report dealing with the trade of Tientsin for the year 1907-8 states that during the last two or three years the system of tramways worked by the "Compagnie de Tramways et d'Eclairage electriques de Tientsin," a Belgian company, has been considerably extended. Originally designed only to make a circuit round the Chinese city along the boulevards formed by the demolition of the old city walls, with an extension along the Chinese Bund, the system was carried across the river to the Austrian concession by a bridge opened in November, 1906; and in May, 1907, an agreement was concluded for running the line through the main street of the Japanese concession, thus providing a direct route between the foreign settlements and the Chinese city, apart from the route through the Russian, Italian, and Austrian concessions on the other side of the river. There are between eight and nine miles open to traffic, nearly all double track. The electric lighting business of this company has also greatly developed in recent years, the receipts having increased from £4,680 in 1907 to £6,240 in 1908.

DEVONPORT: ***Summonses re Tramway Service.***—The summonses issued by the Corporation against Devonport and District Tramways Co., Ltd., for suspending its service of cars upon certain of the leased lines were heard before the Devonport magistrates last week. The Town Clerk stated that the object of the summonses was not to exact money from the company, but to compel them to carry out the terms of their agreement, viz., to run a reasonable service upon the lines leased to them by the Corporation. If the company would run the same service which they ran previous to the discontinuance, or a reasonable service which might be agreed upon, the Corporation would consent to a nominal penalty. This course was not assented to by the company, and the hearing of the summonses was proceeded with. The Town Clerk said the Corporation would therefore ask for the maximum penalty of £5 per day in respect of certain days in January, February, March, and April, as the company had wilfully and deliberately committed a breach of the agreement with the Corporation. For the company it was claimed that the agreement in question had become an unreasonable one, the company having to pay a rent of £3,900 per annum for the lines in question, and also to take all the energy they needed from the Corporation at 1·66d. per unit. This meant that the requirements of the agreement could only be complied with under a very serious financial loss to the company, and therefore, taking all things into consideration, the agreement was not in the public interest. The magistrates will consider their decision.

DOVER: *Tramcar Speed Indicators.*—The Tramways Committee have received a letter from the Board of Trade inquiring whether any, and if so what, steps have been taken in the matter of the fitting of speed indicators on the Council's tramcars. The general manager states that from inquiries he had made he understands that no satisfactory type of indicator has yet been produced. Consequently the Town Clerk has been instructed to reply that the subject is under consideration, but that until it is satisfactorily proved that an accurate indicator can be produced, the committee deem it inadvisable to incur any expenditure in the matter, and further that as the Dover system is such a small one and the stopping places are so numerous, in the opinion of the committee the provision of such indicators is unnecessary, and would serve to distract the driver's attention from their work.

EDINBURGH: *Electric Lighting Surplus.*—The question of the manner in which the surplus upon the electric lighting undertaking for last year shall be allotted has been postponed for the present.

FINCHLEY: *Public Lighting.*—The Local Government Board have communicated with the Council concerning the recent application for sanction to a loan of £2,200, for the purposes of street lighting by electricity, asking if the Council has had before it the comparative cost of street lighting by gas and by electricity. The Council have replied that this point has always been considered by them. Their letter continues to the following effect:—"As regards the question of the illuminant to be used for the streets, the Council consider they are the best judges of the matter, and do not feel that they can submit to any outside pressure to force upon them an illuminant of which they do not approve, and which they consider for the present purpose is not so satisfactory as the one which they propose. They respectfully submit that the point which the Board is called upon to decide is whether a loan should be granted for the necessary sum to enable arc lighting to be installed, and not as to whether gas or electricity should be used."

FRINTON-ON-SEA: *New Generating Plant.*—The Frinton-on-Sea Electric Light & Power Co., Ltd., have recently added a 150-h.p. suction gas engine plant to their generating station.

GLOUCESTER: *Extension of Area.*—The Corporation have given notice of their intention to apply for a Provisional Order authorising them to supply electricity in certain portions of the Rural District contiguous to the city boundaries.

Electrical Students.—On the recommendation of the Electricity Committee, two sons of Gloucester residents are to be allowed to spend part of their technical college vacation as unsalaried assistants in the power station.

GRIMSBY: *Street Lighting.*—A statement is to be prepared for the information of the Electricity Committee giving the relative cost of gas and electricity for street lighting candle-power for candle-power.

HULL: *Preferential Charging.*—At the last meeting of the Electric Lighting Committee, Councillor Costello alleged that in offering power users a discount of 2½ per cent. they were giving

Digitized by Google

"preference" to these consumers at the expense of the lighting consumers, who had really formed the foundation of the electricity undertaking. He therefore moved a resolution to the effect that a similar discount be allowed to the lighting consumers, but there was no seconder, and the matter dropped.

ILFORD: *Electricity Accounts.*—For the year ending March 31st the income of the electricity undertaking was £28,721, leaving a gross balance of £10,678, or £1,000 more than in the previous year. After deducting payment of interest and instalments of loan, there was a surplus of £1 1s. 11d., as against a loss of £375 last year.

JAPAN: *Electrical Imports.*—The imports of electrical machinery, *i.e.*, dynamos and motors, into Japan during 1908 amounted to £209,200, compared with £180,900 for the previous year. Great Britain's share of this, however, declined from £55,000 to £37,700; America advanced from £101,000 to £141,000; Germany from £22,300 to £30,000; whilst from other sources the imports decreased from £2,600 to £500. The imports of other electrical goods amounted to £170,600, compared with £78,600 in 1907. Telephones, which have a separate classification, amounted to £11,500, against £10,700.

Yokohama Harbour Works.—In connection with the new harbour works at Yokohama, a 50-ton fixed electric crane is being erected, whilst, in addition, there will be 30 electric travelling cranes and 32 electric capstans. A power-house containing four 250-kw. generating sets is being erected.

LONDON: *Islington: Street Lighting.*—At the meeting of the Council on July 30th a long report was received from the special committee appointed to inquire into the position of the electricity undertaking with special reference to arc lighting. They pointed out that the price charged by the other Metropolitan Borough Councils varied from 1·11d. per unit in the case of Hackney to 2·34d. in the case of Hampstead, the average price for the whole of the units supplied for public lighting being 1·58d. In no less than six cases the price is fixed as 1½d. or under. It had been estimated by the present Borough Treasurer that the total cost, including capital charges, of the production of current for public lighting in Islington amounts to approximately 1·75d. per unit. After a discussion it was resolved to fix the figure for public lighting at £12,100 per annum, which will be a reduction of £3,700 compared with the present cost.

Westminster: Street Lighting.—The Works Committee of the City Council report having received a communication from the St. James's and Pall Mall Electric Light Co., Ltd., stating that a certain number of the sixty-six arc lamps in the parish of St. James need replacing, they having been in continuous use for thirteen years. The Company proposed that the lamps that are past repair should be eliminated and spare lamps obtained for renewing the eighteen lamps in Regent Street, between Oxford Circus and the Quadrant, and that duplex Excello flame arc lamps fitted with dioptric inner globes be used. The cost of the alteration will amount to £292 10s., or £16 5s. per lamp, and the company asked the Council to defray half this cost. The proposed new lamps would consume 460 watts, and give a mean hemispherical candle power of about 1,600 with a maximum of about 2,400. Subject to the company guaranteeing a minimum candle power of 1,400, the Committee approve of the proposal, provided the company's contract for public lighting, which expires on November 10th, 1910, is strictly adhered to in all other respects.

London County Council: Tramways.—The reconstructed Aldgate-Bow route was inspected last week on behalf of the Board of Trade by Lieut.-Colonel von Donop, and the line was opened to the public on Monday.

MEXICO: *Power Company's Plant.*—The London office of the Mexican Light & Power Company, Ltd., has received cable advice from Mexico to the effect that the unprecedented drought which prevailed during the first half of the year is now being followed by a very heavy rainfall, which enables the company not only to operate its entire load by water power, but also to store water in both the Laguna and the Los Reyes reservoirs to meet the requirements of the dry season of next year.

PETERBOROUGH: *Electricity Accounts.*—After meeting interest and sinking fund charges, the accounts of the Corporaporation electricity undertaking for 1908-9 show a profit of £89.

SALFORD: *Tramway Accounts.*—The municipal tramway accounts for the year to March 31st show a decrease in the gross receipts of £1,553 14s.; the average receipts per car mile are much less than the figure for the previous year, due principally to the general trade depression, the concessions with regard to fares, and to the lengthening of many of the stages. The reduction in receipts per car mile amounts to 0·60d., which represents a loss in earnings of approximately £14,463, and taking into account the mileage run during the year the net profits amount to £17,264, compared with £28,206 for the previous year. The General Manager points out that it was anticipated that corresponding additional traffic would result from the granting of the concessions mentioned above, but this has not proved to be a fact, and at the conclusion of the trial period in August next it will be necessary for the committee to review these concessions, and most probably revert to many of the conditions previously existing, otherwise it will be impossible to continue to make a similar grant in relief of the rates as in past years, and at the same time adequately provide for the requisite renewals required to the permanent way and the other branches of the department. The number of passengers carried was 45,975,584, compared with 45,771,611 in the previous year; the car mileage being 5,785,469 against 5,486,150. Of the net profits of £17,264, the sum of £17,000 has been contributed to the relief of rates and the balance carried to depreciation and renewals fund. The receipts per car mile were 9·84d., and the expenses 6·428d.

SPAIN: *Electric Tramways.*—A British Consular report states that very little was done during 1908 towards the extension of tramway lines in Barcelona, the three companies, two Belgian and one German, owning the entire system rather paying their attention to the improvement of the permanent way and of the rolling stock. There have been several concessions applied for regarding small extensions of the German lines, and one of considerable importance granted to a Spanish company for a line from Barcelona, crossing the neighbouring hills to the north of the city, and continuing through the valley beyond as far as the towns of Rubi and Sabadell, a total distance of some 15 miles; but up to the present the promoters have not been able to secure sufficient capital. A Belgian syndicate which some years ago bought up the British company controlling what may be termed the metropolitan lines, has now amalgamated with the company which works the suburban lines to Sarria and Sans, the combined capital being about £1,000,000. The existing tramways in Corunna are worked by mules and run very indifferently, working expenses being very heavy. It is proposed to convert the whole system (four miles) into an electric tramway, and to extend the existing line some five miles on the road to Betanzos, so as to open up communications with the many villas and estates to the west of the town. Negotiations with a Belgian syndicate have fallen through, and correspondence is now going on with British and other groups with a view to the speedy settlement of this scheme.

Electrical Machinery Markets.—Commercial Intelligence points out that electrical machinery is being imported in the Spanish district of Gijon in increasing quantities, mainly from Germany. Two German firms have established themselves at Gijon with considerable staffs of German employés. The local British Vice-Consul finds that no serious effort has yet been made by British manufacturers of electrical machinery to enter this market.

Electricity Supply.—A British Consular report states that the lighting of Corunna is undertaken by two companies, La Société d'éclairage de la Corogne et Vigo and the Sociedad Co-operativa Electrica, both of which make use of a stream near Puentedeume, near Ferrol, for the purpose of generation. Great competition existed between these two companies by which the consumer benefited, but they have now come to an arrangement and work together. The lamps and fittings employed all come from Germany, and are supplied by agencies in Madrid. The Compañia Barcelonesa de Electricidad, a German concern, have during the past year considerably increased their buildings and the machinery in their power station. Their total horse-power is now about 25,000, and the total capital invested some £800,000. They supply about two-thirds of the electric light and power in this city, the remaining third being supplied by a Spanish company.

SOUTHAMPTON: *Wiring Scheme.*—Mr. H. F. Street, the Borough Electrical Engineer, recommends the Council to invest £2,000 of the electricity reserve fund in free wiring. With this amount it would be possible to instal about 2,600 lamps at a cost of 15s. per lamp, which was above the average of the cost of installation in Southampton. The revenue on this from sales of electricity at ordinary rates would be no less than £600, to which would be added the extra cost for free wiring, which, say at 1d. per unit, would amount to not less than £200. This scheme had the support of all the principal wiring contractors of the town, who saw in the proposal a considerable increase of business coming to them. The matter has been referred to the Parliamentary Committee.

SURREY: *Overhead Wires.* It has been reported to the County Council that a clause for the protection of the Council had been inserted in the Hindhead and District Electric Lighting Order, and though the placing of overhead wires had not entirely been prohibited, the erection of them would be subject to the consent of the Board of Trade and the local authority, and the Board had intimated that they would not in any case give their decision without affording the County Council an opportunity of being heard.

SUTTON: *M.A.B. and Metal Filament Lamps.*—At the meeting of the Metropolitan Asylums Board on Saturday it was reported that the South Metropolitan Electric Tramways & Lighting Co., Ltd., had agreed to the installation of auto-transformers and metallic lamps at the Children's Infirmary, Carshalton, and the Downs School, Sutton, under an agreement which will extend to December 31st, 1918, the company undertaking not to raise their price of current for lighting purposes above 2½d. per unit.

TYLDESLEY: *Provisional Order Transfer.*—The Council have decided to accept £480 as consideration money on the completion of the transfer of their electric lighting order to the Lancashire Electric Power Co.

Digitized by Google

UNITED STATES: *Electric Traction.*—A British Consular report, dealing with the districts of Portland and Oregon, states that during 1908 large extensions of electric lines and rebuilding of many of the older lines have been in progress during the year. Many new lines are projected, both for passengers and goods, some of these being in districts remote from trunk railways. Heavier rails and rolling stock are now used than formerly.

WAIPORI (N.Z.): *Electricity Accounts.*—The annual report of Mr. E. E. Stark, City Electrical Engineer, states that in February, 1909, tenders were received, and have since been accepted, for the duplication of the present plant, embracing water-wheels, governors, generators, exciter, Tirrill regulators, step-up transformers, step-down transfomers, pipe line, and three-core underground cables, amounting to £13,000. Mr. Stark estimates that this will be a more economical arrangement than putting down steam plant. A new battery has been installed at the converter station for equalising the tramway load, and a milling booster has also been added to the plant. The total revenue for the year covered by the accounts was £19,775, and the expenditure £9,412. After meeting capital charges, bank overdraft, &c., there is a net profit of £854. Since September the Council have accepted applications for power supply amounting to 672 h.p. from thirty consumers, with the proviso that the Corporation has the right to require the non-use of power during peak load hours.

WEST ASHFORD.—Mr. Mark Parker, of Dover, has notified his intention of applying for a provisional electric lighting order.

WEST BROMWICH: *Council and Tramways Co.*—The Highways Committee have presented a report stating that in December, 1905, it was decided to enter into an agreement with the South Staffordshire Tramways (Lessee) Company, Ltd., whereby in return for concessions in the matter of having a less frequent service than stipulated by the original lease, the company would take a minimum supply of 900,000 units of electrical energy per annum instead of 300,000 at the prices fixed by the lease. The company, however, had refused to execute the agreement, and in a recent letter declined to continue negotiations. In view of this the committee had instructed the Town Clerk to write to the tramways company requiring the agreement to be sealed within fourteen days, or in default take proceedings to compel them to comply with the terms of the original lease. The report was adopted.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Miscellaneous

HOLLAND.—According to the *Board of Trade Journal*, there are very good openings for electric motors, especially of the smaller kind of from 2 to 5 h.p. and over, as electric motors manufactured in Holland are not considered to be of very efficient workmanship.

SERVIA.—The *Board of Trade Journal*, quoting from a report in the *Bulletin Commercial* (Brussels) draws attention to the good openings in that country for electric lighting and kindred appliances, and to the necessity not only for supplying articles of good quality at reasonable cost, but also for developing the market on the spot by means of personal visits. The establishment in Servia of a depôt where electrical material could be seen by persons interested would, according to this report, be the most effective way of increasing business.

SOUTH AFRICA.—A proposal is before the Krugersdorp Council for the construction of an electric tramway between Krugersdorp and Randfontein.

YORK.—The Corporation invite tenders for 18 double-deck electric tramcars and one watering car. Particulars from the City Electrical Engineer, and tenders to the Town Clerk by August 27th.

Generating Stations, Sub-stations, Mains &c.

CARLISLE.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £5,750 for extensions to the electricity undertaking.

EDINBURGH.—The Corporation require a motor alternator (see our advertisement this week).

EPSOM.—The Local Government Board inquiry into the application of the Urban District Council to borrow £1,500 for the purpose of electric lighting was resumed last week. The Inspector pointed out that there had been a loss of £7,122 on the undertaking, and they had been going on from year to year with a steady loss of £900 per annum. In the course of further discussion the Inspector said that it appeared that the undertaking had been too ambitious altogether at first, and that the Council had been carrying on a system of lighting, and did not even know what it cost. There had been a loss on both the public and private lighting, and the position in regard to the former was that the price charged had never been worked out.

GRIMSBY.—Tenders are to be invited for cables.

LONDON: *London County Council.*—Tenders are invited by September 14th, for high-tension and low-tension cables, tramway feeder pillars, and stoneware ducts. (Full particulars in an advertisement on another page.)

LONGTON.—Sanction to a loan of £1,250 for mains extensions is to be sought.

MIDDLESBROUGH.—The Local Government Board have sanctioned the borrowing of £18,922 for mains, extensions, &c.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—School, East Ham (£13,229). Architect, R. L. Curtis, 11 and 12 Finsbury Square, E.C. Builder, W. J. Maddison, Clarkson Street, Canning Town.

N.E.—Additions to Eastern Hospital, The Grove, Homerton (£2,058). Builders, Pasterfield & English, 58 Sunnyhill Road, Streatham.

S.W.—Rebuilding shop premises, High Road, Streatham (£9,420). Architect, F. Bethell, 23 Queen Anne's Place, Bush Hill Park, Enfield.

W.C.—Rebuilding Post Office at junction of Museum Street and High Holborn.

PROVINCES.

ABERDARE.—New laboratories, Intermediate Schools (£3,093). Architects, D. Pugh-Jones, Cardiff.

BURSLEM.—Bakery (£3,200). Architect, R. Worcester, Balloon Street, Manchester.

BARNSTAPLE.—School (£4,000). E. G. Saunders, Borough Architect, Barnstaple.

HEREFORD.—Additions to Council School (£900). County Surveyor, G. H. Jack, Hereford.

ILFORD.—School, Salisbury Road. Architect, A. S. R. Ley, 54 and 55, Bishopsgate Street Without, London, E.C.

KING'S NORTON.—School. Architect, J. P. Osborne, 95, Colmore Row, Birmingham.

PENARTH.—New laboratories at Intermediate Schools (£4,169). Architect, D. Pugh-Jones, Cardiff.

RICHMOND (Dublin).—The Local Government Board inquiry into an application by the Richmond Asylum authorities for a loan of £4,500 for electric lighting was concluded last week. The Dublin Corporation are willing to enter into a contract for the supply of electricity at 3d. per unit for three years.

ROMFORD.—School (£7,994). Builders, J. S. Hammond & Sons, Romford.

WORCESTER.—St. Martin's new church (£8,868). Architect, G. H. Fellowes Prynne, 6, Queen Anne's Gate, Westminster.

WATFORD.—School, Cassiobury Park, for the Governors of the Watford Grammar School.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The *Australian Mining Standard* states that in connection with the Sydney Corporation's recent tenders for a two years' supply of motors, that of Messrs. Noyes Bros., of Melbourne, although not the lowest, was accepted. Messrs. Staerker & Fischer, of Melbourne, were the lowest tenderers under one section of the contracts, but their tender was not accepted owing to their motors being manufactured by a German firm, namely, the Allegemeine Elektricitäts Gesellschaft, of Berlin. Apparently this latter tender was rejected solely on this ground, and Messrs. Staerker & Fischer have written a long letter of complaint to the Corporation pointing out the unfairness of this, in view of the fact that no indication was made in the advertisement calling for the tenders, that only British goods were to be tendered for. They therefore ask that their expenses in the matter should be refunded to them.

The Western Australia Postmaster-General's Department has accepted the tender of the International Electric Co. of London for the supply of 30 miles of covered wire at £2 7s. 6d. per mile.

CHINA.—*Commercial Intelligence* states that the Eastern Trading Co., Ltd., has been appointed by Viceroy Tuan Fang to erect electric lighting plant for the city of Nanking. The main contractors are Messrs. Babcock & Wilcox, Ltd., and Messrs. Belliss & Morcom, Ltd. The contract was secured in the face of strong competition, 26 firms of various nationalities competing for the contract.

Digitized by Google

EASTBOURNE.—The Council have accepted the tender of Messrs. Lassen & Hjort at £155 for water-softening plant.

SALFORD.—The Council has accepted the tender of Messrs. Harland Bowden & Co., at £765, for re-wiring at the Royal Technical Institute.

GERMISTON (S.A.).—The Council have entered into a contract with the Victoria Falls and Transvaal Power Co. for a supply of electricity in bulk for three years.

ILFORD.—The Council have accepted the tender of the Brush Electrical Engineering Co., Ltd., for the supply of four tramcars at £561 each.

COMPANIES' MEETINGS AND REPORTS

SAO PAULO TRAMWAY, LIGHT & POWER CO.—The report for 1908 states that the gross earnings, $2,287,410, show an increase over the previous year of $175,887, while the net earnings, $1,504,359, show an increase of $108,486. The sum of 92,065 has been charged to the contingent account for renewals and replacements. To meet expenditures of this nature, and to provide for the reconstruction of tracks, which will become necessary in connection with the general plans of the city in the way of widening streets, reducing grade, &c., the directors have thought it well to set aside $300,000 from the earnings of the year, as a definite provision for renewals.

CHATHAM & DISTRICT LIGHT RAILWAYS CO.—The accounts for the half-year ended June 30th, 1909, show receipts amounting to £20,363, and expenses to £12,820. Rent of Rochester Corporation lines and interest on debentures absorbed £3,105, and after adding the balance brought forward there is a sum available of £4,669. A dividend of 5 per cent. per annum is recommended on the preference shares, and the balance of £1,730 carried forward.

DIRECT UNITED STATES CABLE CO.—The report for the June half-year shows a net profit of £35,915, including £4,506 brought forward. A final dividend of 4 per cent. per share is proposed, together with a bonus of 1s. per share, making 4½ per cent. for the year. At the meeting last week, the report and accounts were adopted.

MEXICO TRAMWAYS CO.—The report for 1908 shows a net revenue of 611,350 dollars. The sum of 371,350 dollars is carried forward after paying four quarterly dividends each at the rate of 4 per cent. per annum.

MEXICAN LIGHT & POWER CO.—The gross earnings for 1908 were 2,938,474 dollars, and the expenditure 1,080,570 dollars. The Board have written off the following sums:—For increased cost of construction due to the drought and other special conditions, 478,789 dollars; depreciation in transformers, meters, electric supplies, &c., acquired on the purchase of other companies, 100,000 dollars; bad and doubtful debts, 47,414 dollars. A dividend of 3½ per cent. has been paid for the year on the ordinary shares, and a balance of 910,823 dollars is carried forward.

ANGLO-AMERICAN TELEGRAPH CO.—The total receipts from January 1st to June 30th, 1909, including the balance brought forward, amounted to £211,759. The traffic receipts show an increase of £14,503. The working expenses of the half-year amounted to £72,345, being a decrease of £950. The directors have set aside the sum of £10,000 to the renewal fund, leaving a balance of £129,414. Quarterly interim dividends of 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, were paid on May 1st, 1909, absorbing £52,500, and second quarterly interim dividends, amounting to £52,500, will be paid on July 31st, 1909. The balance o f£24,414 is carried forward. At the meeting last week, the report and accounts were adopted.

CENTRAL LONDON RAILWAY CO.—The report for the half-year ending June 30th states that, compared with the corresponding period in 1908, there has been a decrease of £19,646 in the receipts, and of £258 in the working expenses. The balance carried to net revenue is £64,139. After providing for interest on the debenture stock, &c., there remains a balance of £84,093, and the directors recommend the declaration of the following dividends:—On the undivided ordinary stock 3 per cent. per annum for the half-year; on the preferred ordinary stock 4 per cent. per annum for the half-year; dividend on the deferred ordinary stock not being payable until the result of the working of the whole year is ascertained, the remaining balance of £44,750 14s. 2d. is carried forward to next half-year. The number of passengers carried during the half-year was 18,989,109, compared with 19,901,750 in the corresponding period of last year, which, however, included traffic to and from the Franco-British Exhibition. The Imperial International Exhibition, though yielding some additional traffic, has not, up to the present, repeated the remarkable results of last year. The rearrangement of fares has not been in force sufficiently long for the directors to express a decided opinion on the experiment. The meeting is to-day (Thursday).

DUBLIN UNITED TRAMWAYS CO.—For the half-year ended June 30th the amount available for distribution is £42,526, out of which it is recommended that dividends be paid for the half-year at the rate of 6 per cent. per annum on the preference shares, and at the rate of 6 per cent. per annum, free of income tax, on the ordinary shares, leaving £7,501 to be carried forward. At the meeting last week the report and accounts were adopted. Mr. W. M. Murphy, who presided, said the service of express cars to Dalkey had been much appreciated, and it was the intention of the company to apply to the Board of Trade for sanction to run these cars at higher speeds. In the course of his speech the Chairman drew attention to the very low receipts per car mile on the Dublin system, compared with the average of other towns, viz., 8½d., and in view of this, the fact that they had been able to maintain their moderately good results, whilst the majority of tramway undertakings were falling away, was very satisfactory.

METROPOLITAN RAILWAY CO.—At the half-yearly meeting on Wednesday last week, the report and accounts given in our last issue were adopted. Sir Charles McLaren, who presided, said there had been increases during the half-year from the traffic on practically all sections of the line, and there could be no doubt that the public were beginning to realise, in a way they had not done before, the advantages of electric traction on railways. It was common knowledge that the "White City" traffic was nothing like so great as last year, and they were keeping down expenses to the lowest point, in order to minimise the comparative loss as much as possible.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO.—The report for 1908 states that the hydroelectric plant at Rio das Lages is practically finished. The transmission lines have been completed, and an independent telephone line constructed during the year, connecting the power house at Rio das Lages with the terminal station at Rio de Janeiro. Three 800 kw. motor generators have been installed for the tramway service. The sub-foundations have also been completed for the gas engine units which will be installed as a reserve for the public street lighting. While the new electric tramways were opened late in the year it has been impossible to utilise the electric cars to their full advantage on account of the reconstruction. Close attention has been paid by the company to the development of its power business. Until January 1st, 1908, the various companies which are controlled by this company were operated as separate concerns, but from this date the operation of these companies was taken over by this company under operating contracts and leases, so that the earnings of the various companies appear for the first time in the financial statements of this company. The net revenue after deduction of operating expenses, maintenance, taxes, and other fixed charges in Rio de Janeiro was $2,730,434, from which must be deducted the fixed charges and interest on loans at head office, leaving a net surplus after the payment of all expenses and fixed charges for the year of $870,256. An opportunity being presented of acquiring about 75 per cent. of the shares of the Jardim Botanico Tramways Company, thus assuring a controlling interest of this company, the Board considered it wise to purchase these shares, as that company has a large and lucrative business in one of the best residential sections of the city.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—The report for the June half-year states that, after providing for debenture interest there is an available balance of £1,153, out of which the directors recommend the usual half-yearly dividend on the 5 per cent. preference shares, which will absorb £475; that £250 be allocated to Messrs. Dick Kerr & Co. further on account of the sum still due to them on account of electrical equipment, thus reducing that debt to £350, and that the balance of £428 be carried forward.

GREAT NORTHERN AND CITY RAILWAY CO.—The total receipts for the six months ending June 30th amounted to £40,802, and the expenditure to £21,040. The net revenue amounted to £19,761, which is insufficient to meet the company's fixed charges for the half-year. The sum of £3,209, which has been provided from outside sources, has enabled the company duly to meet these charges. The number of passengers carried during the six months, including season ticket-holders, was 6,041,755, as against 6,875,602 for the corresponding period last year. The decrease in the number of passengers carried and in the receipts earned during the half-year is mainly attributed to the competition of the London County Council tramways.

SINGAPORE ELECTRIC TRAMWAYS.—The report for 1908 shows an excess of revenue over expenditure of £24,294, against which has been charged debenture interest, depreciation, and royalty, amounting to £28,335, showing a loss for the year of £4,040. The severe depression in trade in Singapore which set in towards the end of the year 1907 showed no abatement during 1908, and as a consequence the tramway revenue shows a decrease of $20,176 as compared with 1907. The demand for energy for lighting and power purposes shows a satisfactory increase—the receipts from this source in 1908 being 94 per cent. higher than in 1907.

SOUTH AMERICAN LIGHT AND POWER CO.—The report for the year to March 31st states that the net profit for the year is £5,422. The directors recommend the payment of a dividend of 4 per cent., and also the payment of interest at the rate of 4 per cent. per annum on the £15,961, further capital expenditure incurred during the year by the railway company, which amounts to £274. The balance of £627 is carried forward.

Digitized by Google

LANCASHIRE ELECTRIC POWER CO.—The annual meeting was held in London on Thursday. Mr. H. F. Parshall, who presided, said that the reorganisation of the company was not completed till the end of 1908, so that the new directorate had only been in existence six months. Since the reorganisation steady progress had been made, and more satisfactory contracts had been entered into. The Board of Trade had sanctioned the transfer to the company of a considerable number of lighting orders held by local authorities. One of the most satisfactory developments was in connection with the supply of electric power to collieries. During the last six months the output had increased something like 30 per cent., while the total costs of production were actually less than those of the corresponding period of last year, the revenue increase being £1,500. This satisfactory increase was to be accounted for by the fact that the advantages of the company's supply were becoming better understood by the Lancashire manufacturers. During the year a Local Government Board inquiry was held at Radcliffe, in which district their power station was situated. The attitude taken up by the Local Government Board was to discourage the development of the Radcliffe Council's undertaking for the purposes of power generation, and a recommendation was made to the effect that the position of this company should be taken into consideration by Radcliffe. The directors had many times met the Radcliffe authorities with a view to arriving at a better understanding, but their efforts had so far met with no encouragement. For this reason it had appeared to the directors advisable to apply to the Board of Trade for a Provisional Order to supply electricity in the Radcliffe district, as there were most important customers in the district who were willing to deal with this company.

BLACKPOOL & FLEETWOOD TRAMROAD CO.—The report for the half-year ended June 30th states that, including the sum brought forward from last half-year, the balance, after providing for debenture interest, is £4,685, and the directors recommend a dividend at the rate of 4 per cent. per annum, writing off £750 to depreciation reserve and £500 to general reserve account, leaving a balance of £435 to be carried forward. The number of passengers carried during the half-year was 963,460.

MISCELLANEOUS CITY NOTES

OXFORD ELECTRIC CO.—A dividend at the rate of 5 per cent. per annum on the ordinary shares is announced.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—An interim dividend for the June half-year at the rate of 10 per cent. per annum, less tax, is announced.

METROPOLITAN DISTRICT RAILWAY CO.—A dividend of 5 per cent. per annum on the Four per Cent. Guaranteed Stock is announced, placing £10,000 to reserve for renewals. A year ago the dividend on this stock was 1¾ per cent.

W. T. HENLEY'S TELEGRAPH WORKS CO.—An interim dividend on the preference shares at the rate of 4½ per cent. per annum, less income tax, and on the ordinary shares at the rate of 10 per cent. per annum, free of income tax, for the half year ending June 30th last, has been declared.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY CO.—An interim dividend at the rate of 5 per cent. per annum on the ordinary shares of the West End undertaking has been declared.

CHARING CROSS, EUSTON, & HAMPSTEAD RAILWAY CO.—A dividend at the rate of ¾ per cent. per annum is announced.

BAKER STREET & WATERLOO RAILWAY CO.—A dividend at the rate of 3 per cent. per annum is announced upon the ordinary shares, except those held by the Underground Electric Railways Co. of London, upon which the dividend will be at the rate of 1½ per cent.

GREAT NORTHERN, PICCADILLY, & BROMPTON RAILWAY CO.—A dividend at the rate of one per cent. per annum is announced.

METROPOLITAN ELECTRIC SUPPLY CO.—An interim dividend of 5 per cent. (less tax) is announced upon the ordinary shares for the June half-year.

SOUTH METROPOLITAN ELECTRIC TRAMWAYS & LIGHTING CO. The question of the payment of a dividend on the preference shares has been deferred until the accounts for the whole year are in the directors' hands.

Engineering Units of Measurement, with Symbols and Abbreviations, British and Metric Equivalents. By J. Ramsay. (London: Simpkin, Marshall & Co.) 1s.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 5s. to £60 15s. (Last week, £60 to £60 10s.)

LARGE GAS ENGINES.—We are informed by the Key Engineering Co., Ltd. (4 Queen Victoria Street, E.C.), who have been for some time agents for the large gas engines manufactured by Messrs. Ehrhardt & Sehmer, of Saarbrucken, that in view of the increasing repeat orders for their engines in this country arrangements have been made for their manufacture in Great Britain by Messrs. Galloways, Ltd. In future the Key Engineering Co. will act as agents, both for Messrs. Galloways, Ltd., and for Messrs. Ehrhardt & Sehmer.

AGENTS.—Messrs. Davidson & Blackadder, of 50 Wellington Street, Glasgow, have been appointed agents for the St. Helens Cable & Rubber Co., Ltd., of Warrington, for the whole of Scotland. Mr. J. W. Logan will continue to represent the St. Helens Co. in the Scottish district as a member of Messrs. Davidson & Blackadder's staff.

ELECTRO-MECHANICAL BRAKE & ENGINEERING CO.—In order to thoroughly reorganise and develop their business, the directors of this company have secured the services of Mr. E. J. Chambers, J.P., M.I.Mech.E., as chairman and managing director. Mr. Chambers is a director of Messrs. Bull ers, Ltd., of Tipton, Hanley, and London, telegraph engineers, and also chairman of Messrs. H. & T. Danks (Netherton), Ltd., of Netherton and London, steam boilermakers.

PROMETHEUS HEATING APPARATUS.—Messrs. Simplex Conduits, Ltd., have entered into an agreement with the British Prometheus Co. whereby they have been appointed sole selling agents for their well-known apparatus, both on the Prometheus "strip" system and on the new silundum system. Special arrangements have been made in regard to facilitating delivery, and large stocks of standard types of electric kettles and other appliances, particularly electric irons, will be carried at the London showrooms and various provincial branches of Simplex Conduits, Ltd. The new department will be under the management of Mr. N. E. Beves, who has acted as London manager for the British Prometheus Co. for some years past.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the Eastern Electrical Syndicate, Ltd., will be held at the offices of the liquidator, Mr. W. H. Stentiford, 1 Broad Street Place, London, E.C., on Tuesday, September 14th, at 11 a.m., to receive an account of the winding-up.

Creditors of the Geneva Tramways Co. (1906), Ltd., are requested to send particulars of their claims to the liquidators, Messrs. A. G. Brand and John Sear, 286 Salisbury House, London, E.C., not later than September 1st.

A meeting of creditors and shareholders of the Uxbridge and District Electric Supply Co., Ltd., was held on Friday, when the liquidation was left in the Official Receiver's hands with a view to a continuance of the company's business. The Metropolitan Electric Supply Co., Ltd., hold £43,000 debentures in the company, and it was in respect of these that compulsory winding-up proceedings were taken. The failure of the company was attributed to want of working capital to fully develop the area of supply granted by their Provisional Orders. Originally, the General Electric Co., Ltd., and Messrs. Callender's Cable & Construction Co., Ltd., financed the company, but these debentures were transferred to the Metropolitan Electric Supply Co., Ltd.

RISE IN PRICE OF CABLE.—We are informed by Messrs. Callender's Cable & Construction Co. that owing to the continued high price of para rubber they are compelled to raise their prices for association grade cables, and therefore until further notice the prices for these cables given in their list dated May 1st, 1909, will be subject to discounts of 15 and 10 per cent. The prices of non-association cables are also increased, and net prices will be quoted on receipt of inquiries.

METAL FILAMENT LAMPS.—In further reference to our note last week under this heading, Messrs. G. M. Boddy & Co. inform us that there is also a very large demand for 32-c.p. 200-260-volt "Metalik" lamps, and it is in fact these and the 16-c.p. 110-volt lamps that are particularly in request. We learn also that the firm have now a 25-c.p. 200-260-volt metal filament lamp ready for the market.

APPOINTMENTS AND PERSONAL NOTES

An assistant lecturer and demonstrator in electrical engineering is required at the Birmingham University, salary £150 per annum. Applications to the Secretary, from whom further particulars may be obtained, by August 14th.

Mr. F. A. Fitzpayne has been appointed general manager of the Leith Corporation tramways in succession to the late Mr. J. Wilson. Mr. Fitzpayne has been on the staff at Leith for some years.

Dover Corporation have appointed Mr. Greenhouse second shift engineer at the electricity works at a salary of £80 per annum. Mr. Osborne, senior shift engineer, has been granted an increase of salary from £110 to £120 per annum.

Digitized by Google

AN ELECTRICALLY-DRIVEN LEAD WORKS

THE name of Messrs. Foster, Blackett & Wilson, Ltd., of the Tyne Lead Works, Hebburn-on-Tyne, has long been associated with the English manufacture of metallic lead products and the lead oxides of commercial use, and the operations of this firm have contributed very largely to the prominent position which Tyneside has held in lead manufacture. The firm are not lead smelters, but devote themselves entirely to the manufacture of lead products, the chief supply of raw material being obtained in the form of pig-lead from Spain, the ore from the mines there being smelted on the spot. At one time the pig-lead used to contain 20 to 80 ounces of silver per ton, which was separated out at the Tyne Lead Works by the Pattinsonian process. Nowadays, however, the silver is usually extracted in Spain. The Pattinsonian process is, however, still very largely worked for the purpose of refining the lead, when great purity is a necessity, such as for white lead making and for sheet lead suitable for chemical works. Chemical lead is made a specialty of by Messrs. Foster, Blackett & Wilson, who are one of the few firms who refine exclusively by the above process, which is admittedly the only one removing with any certainty many of the deleterious impurities. This Pattinsonian process is also interesting to electricians in connection with storage-battery manufacture, where great purity is essential. About a year ago this firm brought itself into line with modern works equipment by taking an electricity supply from the Hebburn undertaking of the Northern Counties' Electric Supply Co., Ltd., and the result of last year's operation has, by the establishment of economical running, fully justified the step taken.

The raw material is brought to the works by water, and a jetty is erected on the Tyne from which a haulage-way, some 200 yards long, and having an average gradient of 1 in 10, affords a path for the passage of trucks carrying lead pigs, oak bark, &c., up the bank, and refined lead, red lead, and white lead down again for sea shipment. The maximum load of each truck when full is six tons, and a uniform hauling speed of seven miles per hour is given by a wire rope passing over a 5-ft. drum at the top end of the track. This was formerly driven by a vertical double-acting steam engine having its cylinder below the crank-shaft. As two of the main objects in view were to obviate delay in conversion and to keep down capital cost, which, as a matter of fact, is unusually low for this class of change-over work, the original gear was used as much as possible throughout the works. In this particular case, the crank-shaft of the engine was taken out and a gear-wheel and countershaft put in, by means of which the drum is now driven by a 60-b.h.p. three-phase slip-ring motor of the British Westinghouse manufacture, running at 760 r.p.m. The boiler used with the former engine is now used as a water-tank.

At intervals on the haulage-way are turntables, from which branch roads lead into the various departments of the works, including the separating house, where the lead billets are refined. At the top end of this house is situated a group of machinery consisting of a cupola blast fan, a circular saw, a lathe for general mill-wrighting work, and a set of flue paddles, which are used in conjunction with the cupola. The cupola is needed for smelting down to pig-lead all the lead residues and slags which are formed during the various manufacturing processes, and which cannot be otherwise reduced. Any lead dust escaping with the fumes from the cupola is effectively felled by the water sprayed up by the flue paddles. Formerly this group of machinery was driven by a horizontal single-cylinder engine of a most ancient pattern. The piston and connecting rod have now been removed, the engine flywheel retained, and the plant driven by a belt from a 20-h.p. Westinghouse motor running at 760 r.p.m. It may be mentioned that the whole of the conversion was carried out without shutting the works down or causing any serious hitch in operation, the longest interval occurring in connection with the haulage gear, and the Christmas holiday was used for this purpose. This necessitated the foundation of practically every motor being made, and the motor fixed on it before the existing steam plant was touched.

The Pattinsonian plant consists of two or three series of pans, each series having 12 pans of 12 tons capacity. Each pan is heated by means of a furnace. The lead is melted in the charge pan, which is usually either the 6th, 7th, 8th, 9th, or 10th pan of the set, according to the quality of the lead, and then cooled down, being stirred continually until the purer lead separates out in the form of crystals, which are lifted out by perforated stirring ladles into the next pan down the series, while the impurer residue gradually works up the line of pots. This goes on throughout the series until the last, or "market pot," contains pure lead, while the impurer residues have worked up to the opposite end of the set. The pure lead can then be run into a mould 8 ft. square, in which a mass of metal weighing 8 tons is formed. Provision is made for lifting this metal by a jib crane, which swings the slab over to the bed of the lead rolling mill. This crane was formerly operated by a two-cylinder doubt-acting steam engine, the crank-shaft and cylinders of which were taken out, a plain countershaft and gear-wheel put in, and the drive effected by a 10-b.h.p. three-phase motor of the slip-ring type, running at 570 r.p.m., operated by a drum controller. The only special mill-wright work necessary was the provision of a bracket for the motor, and the lengthening of the brake-shaft.

The sheet-lead rolling mill, which is the next step in the process, is particularly interesting to electrical engineers, as it is one of the first electrically driven lead mills in the United Kingdom. The steel rolls are each about 20 in. diameter and 8 ft. 4 in. long, the bottom roll being positively driven, the top roll running loose, but giving pressure. In addition to this, there is a series of live rolls standing slightly above the bed of the mill on either side of the main rolls, to facilitate the passage of the lead billet through the mill, and beyond this there are the "dead" rolls for easing the work, the bed being some 120 ft. long. The motor drive is almost lost sight of in contrast to the large flywheel, 19 ft. diameter, and weighing 6½ tons, which was retained to equalise the load on the motor. Formerly this was driven by a two-cylinder horizontal engine of about 200 i.h.p. and 4 ft. 5 in. stroke, working on 60 lb. steam pressure. Upon conversion the crank was taken off and a gear-wheel put in its place. A countershaft carrying a pinion engaging in the gear-wheel is now belt-driven from a 90-b.h.p. slip-ring motor running at 570 r.p.m. By retaining the flywheel it was possible to use the same reversing gear as before, instead of installing a friction clutch which, to transmit such a horse-power, would have been a very expensive item. The reversal is therefore accomplished by the original gear, comprising two pinions keyed on the flywheel shaft, one of which engages direct on to a loose gear-wheel on the roll shaft, the other gearing on to an idler, which in its turn engages with another loose gear-wheel on the roll shaft. By means of a four-jaw double-headed clutch sliding on a feather key on the roll shaft, either one of the loose gear-wheels is engaged to the shaft, and these, of course, revolving in opposite directions, reverse the motion of the mill. When working on short sheets of lead, such reversals may occur as frequently as five times in a minute, which consideration precluded the use of a reversing motor. It has been found that the installation of electric drive has resulted in a bigger output of the mill owing to the more regular speed. In conjunction with this mill is a pair of rolling cutters at each side of the bed for trimming the edges of the sheets when necessary, and also a guillotine for shearing the sheets to length. Both these are operated from the main gearing of the mill. The largest sheets rolled are 8 ft. wide by 45 ft. long, and up to 1 in. thick, or 60 lb. per square foot, while the rolls can turn out sheets as light as 2½ lb. per square foot. For some chemical processes sheets have to be rolled with thick ends, which entails very accurate starting and stopping, and for this purpose the electrical drive is found very convenient. For loading the finished lead from the mill table, a 5-ton jib crane is provided, converted in a similar manner to the one above described, and fitted with a 10-h.p. motor; the motor and controller are on a special bracket swinging with the crane. The crane does not take a complete turn, so that collector rings are unnecessary, and the slewing is done by hand.

Adjacent to the lead rolling mill are two similar plants for turning out lead pipes. Each machine consists of a hydraulic press, which forces the solid lead out of a steel container through a die, a steel core being bedded in the container, the size of the core determining the inside diameter of the pipe. Pipes varying from 3/16 in. to 9 in. inside diameter can be made, a maximum hydraulic pressure of 3½ tons per square inch being exerted on a ram of 18 in. diameter. The flywheel of the three-throw plunger pump, originally steam driven, was removed, and replaced by a 6-ft. pulley, belt driven from a 30-h.p. motor running at 460 r.p.m. This motor is of the slip-ring type in order to obtain variable speed. This is necessary because the speeds at which the various sizes of pipes can be made vary considerably. It should here be explained that wherever slip-ring motors are installed it is for speed variation rather than for starting-up purposes. Where constant speed is allowed, squirrel-cage motors operated by oil-insulated auto-starters of the Westinghouse pattern are installed. The two

Digitized by Google

30-h.p. motors for the pipe presses and the 90-h.p. roll motor are so arranged as to be all in one railed-off enclosure. In addition to the quiet drive obtained, a great improvement in the class of pipe turned out has been found, particularly in the case of tinned lead pipes, owing to the even turning movement of the motor.

The firm do not confine themselves to the making of metallic or "blue" lead, their works for the production of white lead being among the most interesting of their class in the country. The stacks in which blue lead is converted to white lead by the old Dutch process consist of a series of brick chambers running from floor to ceiling. On the bottom of the stack there is first placed a layer of tan bark, upon which stand a number of pots containing acetic acid, and strips of lead are placed on the top of the pots. A flooring of deals is then laid over this series, or "heat," as it is called, and a second one commenced, and so on, until the chamber is full. After about 90 days the stack is opened out, and the metallic lead is now found to be largely corroded and changed to white carbonate with possibly a metallic core. These cores are separated from the white lead by means of corrugated copper rollers and a perforated screen, the blue lead being used over again, and the white lead levigated and ground to a fine pulp by four sets of three pairs of grindstones in series. After being washed by "dollies," the white lead is allowed to settle from the water in a series of settling tanks. It is subsequently dried and packed.

Perhaps nowhere else in the works have the economies of electrical drive been so strikingly demonstrated as in this section. For loading and unloading the stacks nine overhead jib cranes were formerly run by means of an endless rope drive, and a complexity of shafting and bevel wheels from a 50-b.h.p. gas engine running off town gas. For this cumbersome arrangement individual electric drives have been substituted, together with special switches throwing the motors on and off the mains. The motion is transmitted over an ingenious jockey pulley rope drive, utilising gear parts already on the crane, and the slewing, traversing, and hoisting are accomplished from the ground by friction gears. Five cranes now do the work of nine in a much more economical manner, and standing charges are saved by the firm inasmuch as the average rate of work is one crane-hour per day. The two sets of white-lead stones, known respectively as the "high" stones and the "low" stones, were driven by two steam engines, one indicating 120 h.p., the other being a beam engine, 45 years old, with a 5-ft. stroke and 20-ft. flywheel, running at 26 r.p.m. These are all now done away with, and 50-h.p. Westinghouse motors running at 570 r.p.m. drive with a 10 to 1 reduction through belt pulleys mounted upon a countershaft gearing on to the previously existing shafting. These are controlled by auto-starters, and drive the grinding stones, hoists for the blue and white lead from the ground floor to corrugated rollers, stirrers for the ground white lead, screw conveyers, &c. Some special work was required in connection with these motors, both being virtually mounted on pillars forming part of the foundation of the old steam engines.

A large proportion of the white lead is sold in the form of paste paint, for the production of which two Torrance mixing machines of large capacity are used. These are both driven from a single 50-h.p. squirrel-cage motor, geared to the existing line shaft, from which are also driven a one-ton hoist for raising the dry white lead to the machine hoppers, an oil pump, and a dust-extraction fan.

In the manufacture of red lead metallic lead is heated and oxidised in large drossing ovens in the presence of free air, and is thus converted to yellow oxide of lead (PbO) or litharge. This is then put through grinding stones, known as the "casing stones," and then into a washer. The lighter litharge floats over, and is collected and dried, any heavier metallic lead globules settling down and being sent back to the ovens. A 30-b.h.p. motor with spur drive operates this grinding plant, and as considerable overload may occur through careless use, a large faced ammeter with a red line at overload point is placed in view of the operator. This is found better than sensitive fuses or overload circuit-breakers, as these involve delay and injudicious fusing, since induction motors will stand short overloads. The litharge, after coming out of the settling tanks, is taken to a second set of ovens and again roasted, taking up more oxygen and becoming red lead, or Pb_3O_4. This is, after cooling, ground through another pair of stones, operated by the same motor, and finally taken out and dried. The whole of this red-lead plant was originally driven through bevel gearing from the beam engine, which drove the high white-lead grinding plant, so that the electrical drive does away with a lot of complicated gearing. Both the red-lead and white-lead packing-rooms contain Sturtevant fans, about 3 ft. in diameter, running at 900 r.p.m., which collect the lead dust caused by packing. Both these fans are driven by 5-h.p. motors.

A considerable portion of the works is below road level, and the main power cable for the works is brought in from the roadway and conducted on wall brackets for about 80 ft. to a transformer-house situated in front of the old boiler-house for the "high" white-lead stones. It is divided into three sections, the first containing the cable-dividing box and the high-tension fuses, the second being occupied by four 100-kw. single-phase Berry oil-cooled transformers converting from 5,600 primary volts to 600 volts between phases on the secondary, at a frequency of 40, and the third division being devoted to the low-tension fuses and meters. The supply then passes to the main switchboard, where it is divided into five sub-circuits feeding iron-clad distribution boards, which carry fuses for the sheet mill and pipe presses, the hauling engine and cupola, the "low" grinders and paint mill, the "high" grinders and the red-lead works, and the stack cranes respectively. Special care has been taken to protect the motors from dust, loose sheet-iron covers being in most cases fixed over the motors, which covers can be lifted by means of wire ropes passing over overhead pulleys, and are balanced by counterweights—an ingenious arrangement that we do not remember having seen elsewhere. The lighting of the works, which is exclusively by incandescents, is fed from a single-phase transformer converting to 110 volts, and, wherever possible, bare wire pole line construction for the lighting has been adopted out of doors. The whole of the wiring was installed by Messrs. Warren, Beattie & Co., of Middlesbrough, and is of 600-megohm cable, carried on porcelain insulators, mounted on cleats inside the buildings.

The sweeping nature of the change which has been effected can be gauged by the fact that three boilers for the beam engine, two for horizontal engines, one for the haulage engine, and one for the sheet-lead mill have been put out of action, together with a 50-b.h.p. gas engine. The output of every department has been increased: the pipe pressers report a better quality of output, and the red-lead grinding machinery gives better results, owing to the increased steadiness of the drive. The liability to overload in this plant, already referred to, used frequently to pull the steam engine up, and the willingness of the motor has now to be guarded against by the "danger" ammeter. Altogether the firm are very well satisfied with the changed conditions, and we have to put on record their courtesy in allowing us to examine their works.

Continental Bank for Financing Electrical Enterprises in Turkey.—According to an American Consular report, a combination of German, French, Swiss, and Belgian companies has been formed for the purpose of promoting the use of electricity in Turkey. Among the German companies interested are the Kontinentale Gesellschaft fur Elektrische Unternehmungen, the Elektrische Licht- und Kraftanlagen Akt.-Ges., and other firms standing in close relation to the Siemens group. The Allgemeine Elektrizitäts-Ges. group, and the Zurich Bank for Electrical Undertakings, have also joined. The French group includes the Société Générale of Paris, the Banque de Paris et des Pays Bas, the Banque Ottomane, A. Spitzer & Co., of Paris, and Josse Allard of Brussels. The new combination intends, through the Swiss Kreditanstalt, to form a trust company at Zurich. As a beginning, the shares of stock of the Constantinople tramway acquired by the combination will be deposited with the Swiss institution. The entire syndicate is under the leadership of the Deutsche Bank, at Berlin.

German Electrical Enterprise in China.—According to an American Consular report, a certain German firm has had considerable success in securing contracts for the erection of electric lighting plants in several cities in China. This firm, whose headquarters are in Berlin, has a branch house in Shanghai, and others in Tsingtau, Hankow, Tientsin, and the other large ports of the Far East, and a full stock of electric lighting supplies is kept at each branch house. An electric light plant was recently put up in Kirin by this firm. The plant consists of two boilers by Borsig, Tegel, Berlin, supplying steam at 150 lbs. pressure to two high-speed compound engines built by W. H. Allen & Sons, Bedford. The engines are coupled direct to 165-kw. alternators supplying three-phase current at 5,000 volts with a periodicity of 50, which is transformed down to 220 volts for consumers. The alternators were manufactured by the German firm itself. In February the same company also inaugurated the electric light at Soochow, a city of 40,000 inhabitants. In this plant there are three Krupp-Lancashire boilers, supplying steam at 150 lbs. to two Schickau engines coupled direct to German 175-kw. alternators, generating three-phase current at 2,200 volts, the area of distribution being less than in Kirin. Current in transformed down for consumers to 220 volts. The same German company has also secured the contract for lighting Mukden, Manchuria, a city of 180,000 people, and the initial installation will consist of one 350-kw. Belliss set.

REVIEWS OF BOOKS

Electricity in Factories and Workshops. By A. P. Haslam. 312 pp. 7¾ in. by 5¼ in. 70 illustrations. (London: Crosby Lockwood & Son.) 7s. 6d.

"The aim of this book is to place the possible user of electric power in a position to understand the real value of any proposal for the purchase, generation, or use of electric energy." So the author in his introduction; and his object should be attained. The book is divided into three sections dealing with: The Electric Motor and its Accessories; The Provision of Electric Energy; and The Application of Electric Power. It is prefaced by an Introduction which is, in itself, a clear and well-reasoned essay on the subject.

The first section is intended to instruct the non-technical power user in the type and characteristics of the plant he may require, and the illustrations and diagrams of motors and switches should prove helpful in this somewhat difficult matter.

The chapter on Motor Rating and Efficiency should be of assistance to the buyer of motors when deciding between competitive tenders.

The second section is a well-considered statement of the conditions governing the costs of power generation. The meaning of load factor is explained by reference to a simple diagram, and its effect on costs is deduced from a fully worked out power cost account for a gas-engine plant; by easy stages the reader is brought to understand the relative importance of each item which goes to the making up of the total costs. The author shows a clear appreciation of the power user's difficulties in estimating his power costs.

The relative costs of power production by means of steam, oil, "town" and producer gas plants are fully dealt with, and a valuable chapter on Power Station Tariffs enables a comparison to be made with the cost of a public supply. By explaining why a public supply can be given more cheaply in most cases, the doubts of many power users as to the reasonableness of the tariffs charged may be removed.

In the third section special attention is given to the driving of textile machinery, of printing machinery, and of engineering workshops. The collateral advantages of electric driving are well brought out in each case, the chapter on textile driving being especially full and including an estimate of the cost of equipment and running of a 1,600-h.p. spinning mill plant. Reference is also made to the most recent method of driving spinning frames by variable speed motors. A useful chapter is included on the installation of electric motors, and reference made to the new Home Office Rules. The statement made on p. 289 as to the provision of no-volt release switches and stopping devices is not quite correct, as this requirement has not been included in the Rules as issued.

The book is well printed and illustrated, and is notably up-to-date, and can be recommended, not only to those power users who are considering the use of electric power, but also to those electrical engineers who have to do with the public supply of electrical energy.

Lecture Notes on the Theory of Electrical Measurements. By William A. Anthony. Third Edition, revised by A. Ball. 118 pp. 7¼ in. by 4¾ in. 19 illustrations. (London: Chapman & Hall.) 4s. 6d.

This is an American book, written for American students, and will be of little service in connection with the methods of teaching employed in our own country. It is largely composed of short, incomplete sentences which give little information to the student, and we regret to find, in a work intended for educational purposes, that the terms power and energy are confused.

Electrical Laboratory Course. By R. D. Archibald and R. Rankin. 95 pp. 7¼ in. by 4¾ in. 44 illustrations. (London: Blackie & Son.) 1s. 6d.

This book is merely a collection of brief instructions for carrying out somewhat over fifty experiments in elementary electrical science, and does not pretend to be a text-book. The authors have presumed that the student is attending a lecture course which will enable him to understand the objects of the experiments, and give very little in the way of explanation. The book is offered as a substitute for the more usual loose instruction sheets which the student may paste in his note-book.

Ein Neues Schnellbahnsystem: Vorschläge zur Verbesserung des Personenverkehrs. By August Scherl. 122 pp. 11¼ in. by 14¼ in. 55 illustrations. (Berlin: August Scherl.)

Under the title of "A New High-speed Railway System: Proposals to improve Passenger Traffic," Mr. Scherl, who is a book-publisher and business organiser in Berlin, but not an engineer by profession, has issued a book of over 120 pages to bring forward a rather Utopian scheme for revolutionising high-speed passenger traffic. The book is illustrated by some fifty illustrations, including a number of pen-and-ink drawings in a very spirited style, showing the proposed trains, track, and stations. The first part of the book points out the need of higher speeds and more frequent trains, and claims that the electric mono-rail system has advantages over all others. In the second part, the proposed system is explained in detail. It consists in constructing a number of concentric elevated tracks in and around each important town with straight radial tracks to connect them and the different towns. The trains run on a single rail, and are kept in balance by means of a gyroscope on the Brennan principle. Speeds up to 125 miles per hour are to be attained. An elaborate system to facilitate the taking-up and putting-down of passengers, comprising electric lifts which rise up from the street level, and from which the passengers pass direct into the train, is also described. The third part deals briefly with the economical and social aspects of the scheme. No actual figures are given, however, and there is a complete absence of details of electrical equipment, not even the means of collecting the current for the cars being mentioned.

Der Schutz der Hochspannungsanlagen gegen Blitz und Überspannungen. By H. Zipp. (Bibliothek der gesamten Technik, Band 127.) 168 pp. 4½ ins. by 6¾ ins. 109 illustrations. [Hanover: Max Jänecke.] Price 3 marks.

The various causes of excess pressure in transmission lines and cable systems, the effects of earthing, the different forms of gap discharges, and the connections used, and the construction of electrolytic dischargers and water earth-resistances are dealt with in a thorough manner. Where opinions differ, as, for example, as to the advantages of earthing the neutral of three-phase systems, the arguments of both sides are carefully stated. In the author's opinion, earthing the neutral is advisable in all cases to permit the continuous draining of the static charges induced in the system.

Die Elektrizität in der Landwirtschaft. By W. Fuhrmann. (Bibliothek der gesamten Technik, Band 128.) 82 pp. 4½ ins. by 6¾ ins. 37 illustrations. [Hanover: Max Jänecke.] Price 1.80 marks.

Although this little handbook is intended primarily for the farmer, and not for the engineer, a considerable amount of valuable information as to the power necessary for different agricultural machines and the conditions of working is given. A large number of reproductions from photographs of actual installations are also included, and besides the electric driving of machines and ploughs, light railways for local transports, and the lighting of farm buildings are also dealt with. A couple of pages are devoted to the promotion of growth by electrification.

The Influence of Metallic Filament Lamps on the Electrical Industry and on Street Lighting. 11 pp. 7¼ in. by 4¾ in. (The Kilowatt Publishing Co.) Single copies, 3½d., post free; per dozen, 2s. 6d., carriage paid.

This booklet is a reprint from Electrical Engineering of the Paper which was read by Mr. E. E. Hoadley on the metal filament lamp situation at the recent Convention of the Incorporated Municipal Electrical Association and the report of the discussion. It will be found useful to central station engineers and others endeavouring to popularise electric lighting, and to members of electric lighting committees and public authorities, who have the question of street lighting before them.

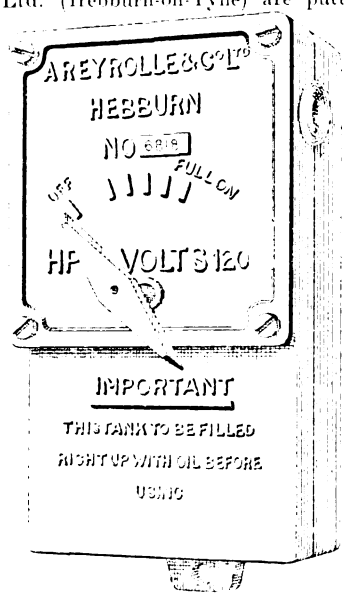
CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

PETROL-ELECTRIC AND ELECTRIC OMNIBUSES.—We have received from Messrs. W. A. Stevens, Ltd. (Victoria Works, St. Peter's Street, Maidstone), a catalogue describing the "Hallford-Stevens" petrol-electric and electric omnibuses and commercial vehicles. This petrol-electric system is specially adapted to omnibus work, as it is suitable for frequent starting and stopping without excessive wear on any part of the gear. The lower cost of maintenance of these vehicles has been shown by the omnibus which has been run in public service in London by Messrs. T. Tilling, Ltd., and has covered 50,000 miles in the last eighteen months. This omnibus was described in Electrical Engineering, Vol. III., p. 85, January 16th, 1908, and the Hallford-Stevens' accumulator omnibuses, of which several are running at Brighton, were described in our article in our issue of June 24th, p. 576, which also gave particulars of the Stevens' system of battery charging which is employed in connection with them.

IRON-CLAD SWITCHES AND FUSES.—A leaflet from the Sun Electrical Co., Ltd. (118 120 Charing Cross Road), describes a new form of iron-clad double-pole fuse-box, in which the cover is so interlocked that both poles cannot be opened simultaneously, as well as some simple patterns of iron-clad switches and single-pole fuse-boxes. A useful pressed brass sweating socket, which has several advantages over the ordinary cast socket, is also listed.

INSTANTANEOUS RADIOGRAPHY



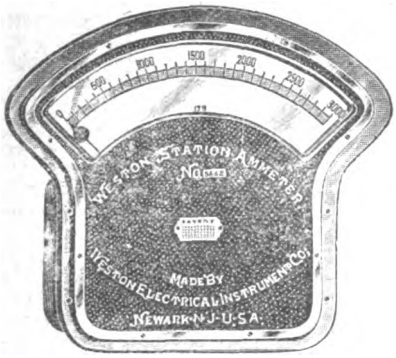
It has constantly been the endeavour of those who take photographs by means of the Rontgen rays to bring down the long exposure to a minimum. Exposures have already been reduced to such an extent as to obviate any possible risk of X-ray dermatitis to the patient, and now the object in limiting the time of exposure is to prevent any indistinctness caused by moving organs. Thus, at the beginning of last year, an exposure of at least twenty seconds was necessary to obtain a radiograph of the chest or heart, and it was then impossible to obtain an instantaneous photograph free from any blurring caused by breathing or by the beating of the heart. With the apparatus now in use, however, it is possible to take such photographs with an exposure of only $\frac{1}{5}$ second. An interesting equipment which has been specially designed for veterinary work was recently shown us by Messrs. Harry W. Cox & Co., Ltd., at 47 Gray's Inn Road, London, W.C. In veterinary work, as, for instance, when a photograph of a horse's hoof is required, we were informed that it is absolutely necessary that the time of exposure should be very short, and this apparatus is capable of taking photographs with $\frac{1}{10}$ second exposure or less.

The induction coil used in this set has a two-section winding, insulated on a new principle, which gives the high capacity between the turns necessary when a heavy discharge is required. The primary takes 90 amperes direct from a 220 volt circuit through a four-point electrolytic interrupter, which gives some 10,000 interruptions per minute. The secondary is designed for a 14-inch spark and a current of 100 milliamperes or more. The rectifier in the secondary circuit, necessary to prevent the flowing of a reverse current, is a triple tube rectifier of the pattern in which the cathode of each tube is enclosed in a narrow tubular space so as to prevent the formation of the dark space. The anode is an aluminium spiral in the body of the tube. The three tubes in this rectifier are connected together so that the degrees of vacuum and consequently the currents flowing through all shall be the same. A Muller "Mammoth" tube in which the target consists of a thick disc of a special alloy, having a melting point even higher than that of platinum, is employed. The target forms the end of a copper cylinder, which gives a large surface for heat radiation. The point on this disc on to which the cathode rays are focussed is raised instantaneously to a white heat, and it is essential that this concentration should be effected, as the Rontgen rays must be generated at a point in order that a sharp definition may be obtained. These tubes are, we are informed, the most intense that have yet been made. The primary circuit includes a timing device, comprising a falling weight arrangement and relay operated switches, with which the time of exposure may be accurately fixed.

Messrs. Harry W. Cox & Co. are shortly bringing out a mercury jet interrupter, which will be suitable for such heavy work as the above. It will have two rotating blades, shaped so as to give a gradual make and sudden break, and two troughs through which mercury will flow continually, and through which the blades are passed. By varying the depth of immersion of the blades in the trough, the current passed can be controlled, and by varying the speed, the interruptions per minute can be given any value up to 7,000. The upper part of the mercury chamber is filled with coal gas as in the previous patterns, this being found much more satisfactory than paraffin. Among the other objects of interest in this firm's showrooms is a couch and apparatus for taking stereoscopic radiographs of any part of the body, and instruments for localising the position of any foreign body or fracture by means of the negatives obtained with this apparatus. The apparatus for viewing these negatives and obtaining a stereoscopic effect can also be seen. An oscillator constructed under the patents of Dr. Horace Manders, and used for producing the continuous oscillations for destroying tissues without burning them, as described in Electrical Engineering, May 27th, 1909, page 495, is also on view. A sustained oscillatory discharge is obtained between zinc and aluminium electrodes, and the knife is connected to the secondary of a high-frequency transformer supplied from the above source. The sparks burn away the tissue without causing any bleeding, as the heat sears the blood-vessels. Another interesting piece of apparatus which we were shown working, is an ultra violet light generator, comprising two small iron electrodes fixed a fraction of an inch apart in a lead glass cup with a quartz cover. When connected to the secondary of an induction coil, a strong beam of ultra-violet rays is emitted through the quartz cover, the operator's hand being protected by the lead glass.

A SMALL ENCLOSED STARTER

The accompanying illustration shows a particularly compact form of motor starter which Messrs. Reyrolle & Co., Ltd. (Hebburn-on-Tyne) are putting on the market. An idea of its small size will be gained from the fact that the overall height of the particular starter illustrated is only about 9½ inches. The whole is fully enclosed and weather-proof. The resistances consist of wire immersed in oil, and the rating is such that a starter may safely be used a considerable number of times per hour. The contacts are placed in a strong magnetic field, which, by suppressing sparking, obviates any trouble due to burning and blackening. As made at present, these starters are provided with no-voltage release only, as it is found that in small sizes there is very little demand indeed for overload releases. The starters have been designed with a view to meeting the demand for small but thoroughly substantial apparatus, and the design is such that cheap and quick production is assured by reducing the number of parts to a minimum.



Small Fully-enclosed Motor Starter.

Brussels Exhibition.—The National Electrical Manufacturers' Association has circularised its members and others with regard to this exhibition. We have already pointed out that the Board of Trade are giving special facilities to British exhibitors, and it is estimated that they will pay £50 out of every £150 expended on British exhibits. Beyond the assistance which the Board of Trade can give, there are many details in which the National Electrical Manufacturers' Association believes it can be of assistance to those who anticipate exhibiting, among others the following:—(1) It is very desirable that an exhibitor should have some information regarding the positions available for his exhibit beyond that which can be obtained from a plan, and this can only be furnished by someone who has seen the buildings, &c. It is, therefore, suggested that joint action should be taken on the part of the members of this Association who are proposing to exhibit by arranging, for someone to report to them on this point. (2) In the case of firms who would be prepared to make a joint exhibit with others, this Association can arrange for such members to co-operate and obtain an arrangement of space, show-cases, &c., suitable for the exhibit. (3) As regards either the sending out of a representative to report or arranging for joint exhibits, this Association would not make any profit and would propose to share the actual costs among the exhibitors. It is thought that it will probably be wise for the exhibitors to appoint a representative to go over to Brussels and to act in conjunction with someone who can be appointed locally. In addition to the above points there are many others where joint action may cause a large saving to the exhibitors, and manufacturers interested are invited to communicate with the Secretary of the Association, Mr. F. B. O. Hawes, at Balfour House, Finsbury Pavement, London, E.C.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 29th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

14,483 08. **Fusing of Metal Filaments to Supports.** S. Marietti. The end of the support or leading-in wire is flattened out, and bent into tubular shape, and the filament is passed through this portion, which is bent at right-angles to the wire. An arc is struck from the tubular end of the support to an electrode, and the whole fused together, while a current of air is directed on to the joint and away from the filament to prevent the hot gases from oxidising the latter. The tubular formation protects the filament from oxidation, ensuring a highly conductive joint, and the use of the air current renders it unnecessary to carry out the fusing operation in a chamber filled with an inert gas. One claim, three figures.

14,700 08. **Speed Regulation of D.C. Motors.** British Thomson-Houston Co., and E. Garton. This specification describes means for keeping the speed constant with varying line pressure. A centrifugal governor driven from the motor shaft controls a contact which, by means of a relay, intermittently short-circuits a resistance in the shunt field circuit of the motor. In the attached drawing, the relay is shown differentially wound. At normal speeds, the resistance remains in the shunt field circuit, but should the speed rise, a coil of the relay is energised and an armature moves, causing the resistance to be short-circuited. When the speed has fallen, the contact is broken, and the resistance re-inserted. Two claims, one figure.

5,018 09. **Tramcar Trolley Head.** J. J. Bennet, L. B. Estes, and R. Evans. This trolley head comprises a fork mounted on a base portion provided with a sector-shaped recess. A sector-shaped lug, with a smaller angular dimension than the recess and attached to the fork, fits into the recess, and permits of a limited rotary movement of the fork, so that the wheel can follow a curve in the overhead trolley wire. Two claims, three figures.

5,415 09. **A.-C. Ammeter.** Dr. S. Guggenheimer and C. Gossen. The value of the current is indicated by a galvanometer operated by thermo-couples heated by the passage of the alternating current. The thermo-couples are placed in bridge connection with not more than two couples in each branch. For heavy currents, two arms of the bridge may be formed by a resistance in series with the main circuit, the two thermo-couple arms being connected in shunt across the resistance and the galvanometer between the junction of the two arms and the middle-point of the resistance, these two points being at equal potential as regards the A.-C. current. Three claims, four figures.

6,106 09. **Resistance Elements.** G. Cooper and F. C. Sharp. These resistance elements are particularly adapted for heating and cooking apparatus, and consist of a thin metal strip wound spirally on edge on a porcelain bobbin, the turns being insulated from each other by asbestos tape also wound spirally. The width of the tape may be less than the width of the metal strip, so that the radiation at the edges may be increased. Special arrangements for bringing out the two ends of the strip to terminals, and for making intermediate tappings, are described in the specification, as well as methods of winding bobbins to give equal heating effects on two or more different voltages. Four claims, seven figures.

10,269 09. **Electric Driving of Looms.** Siemens Bros. Dynamo Works, Ltd. *(Siemens Schuckertwerke-Ges.)*. This patent covers the combination of a flexibly mounted motor with belt driving, and any suitable arrangement for keeping the belt permanently strained notwithstanding the oscillations of the motor. When the motor is caused to oscillate in consequence of the jerks taking place in the loom, the belt is kept strained over the pulleys, and the motor is enabled to exert a comparatively uniform pull without losing grip of the belt or communicating jerks to the loom. The drawing attached to the specification shows a spring-mounted motor and a belt-tightening arrangement, consisting of a pulley fixed to an arm pivoted on the motor frame and controlled by a spring. One claim, one figure.

Grant of Patent Refused

7,125 08. **Shuttle Armatures.** Firm of Robert Bosch. In consequence of opposition, the grant of a patent on this application has been refused. It relates to shuttle armatures for small magneto-generators, in which each armature end or cover is constructed of non-magnetic steel in one piece with the corresponding spindle.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Peck [A.-C. distributing systems] 15,047/08, 13,762/09, and 13,763/09; Gray [Armoured cables] 15,054/08; Diesser [Insulating varnishes] 16,737/08.

Dynamos, Motors, and Transformers: Birkett [Controlling electrically-driven machinery] 15,268/08; Johnson-Lundell Electric Traction Co. and Price [Control of motors] 15,275/08; J. & T. M. Greeves, Ltd., and Eves [Electric driving of spinning frames] 16,144/08; Siemens Schuckertwerke-Ges. [Commutators] 11,904/09; Allgemeine Elektricitäts-Ges. [Brush-holders] 13,231/09.

Electric Ignition: Firm of Robert Bosch [Armatures for magnetos] 3,511/09.

Electrometallurgy and Electrochemistry: Allgemeine Elektricitäts-Ges. [Concentration of nitric oxide] 8,426/08; Felten & Guilleaume-Laymeyerwerke Akt.-Ges. [Ozone apparatus] 6,014/09.

Incandescent Lamps: Trenzen and Pope [Titanium filaments] 14,852 08, and [Metal filaments] 14,853/08; Whyte [Flash lamps] 3,252/09.

Instruments and Meters: Stoneham [Prepayment meter] 15,186 08.

Switchgear, Fuses, and Fittings: Rosenbusch [Time switches] 14,934 08; Thomas and Thomas [Fuses] 20,758 08; Lake *(Cutler-Hammer Manufacturing Co.)* [Multiple motor-starters] 3,517 09.

Telephony and Telegraphy: Murray [Tape transmitter for multiplex telegraph systems] 26,916/08; Siemens Bros. & Co. *(Siemens & Halske Akt.-Ges.)* [Fault indicator for telephone exchanges] 103,09; Bilton [Sheet-metal telephone cases] 9,999 09.

Traction: McComb [Automatic control of speed of vehicles] 15,485 08; Edmonds, and McKenzie & Holland [Signalling apparatus] 15,377/08; Kenworthy [Tramcar sanding pipe] 24,951 08.

Miscellaneous: Warn [Electric aural instrument] 8,210/08.

The following Specifications are open to Inspection at the Paten Office for Acceptance, but are not yet published for sale.

Dynamos, &c.: Moser [Self-regulating A.-C. booster] 8,345 09; Maxaner [Combined centrifugal fan and motor] 15,659/09.

Electric Ignition: Delage and Wood [Gas-burners] 16,341 09.

Switchgear, &c.: Felten & Guilleaume Laymeyerwerke Akt.-Ges. [A.-C. indicators] 8,191/09.

Traction: Durey [Brake] 14,648/09; Westinghouse Electric Co. [Braking apparatus] 15,725/09; Richardson and Cie. de Signaux Electriques pour Chemins de Fer [Block signalling] 15,862 09; Taylor [Signalling] 15,978/09; Ulrich [Brakes] 16,047/09.

Amendments

11,539 08. **Lamp-Reflector and Shade.** O. A. Mygatt. Application has been made for leave to amend the wording of this specification. For full particulars see the Official Journal of the Patent Office for July 28th, 1909, page 1225.

370 09. **Thermo-electric Pyrometers.** W. S. Peake. Leave has been granted to include the Cambridge Scientific Instrument Co., Ltd., as applicants for this patent. The specification has not yet been accepted and published.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, &c.: A. J. Boult *(H. B. Cobb)* [Apparatus for pressing lead covering on cables] 7,862/96; J. Radcliffe [Cable drying apparatus] 8,973/02.

Dynamos, &c.: J. Devonshire *(W. S. Moody)* [Oil cooled transformer] 7,881/96; A. J. Boult *(O. H. and A. F. Pieper)* [A.-C. commutator motor] 7,084/00; British Thomson-Houston Co. *(General Electric Co., U.S.A.)* [Variable-speed polyphase motors] 8,405 04, and [A.-C. commutator motors] 8,404 04.

Instruments and Meters: A. G. Brookes *(L. Sell)* [Prepayment meter] 7,953 99.

Switchgear, &c.: British Thomson-Houston Co. *(W. B. Potter)* [Series-parallel controllers] 7,785/01; C. Russ [Time switches] 8,394 04; W. P. Thompson *(C. Johnston)* [Lamp or motor controlling switch-device] 8,715 04.

Traction: F. E. Case [Multiple-unit control connections] 21,758 98.

Miscellaneous: H. H. Lake *(W. J. Dudley)* [Electric clocks] 7,051 00.

It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

Mr. G. W. Partridge writes us with reference to the article by Mr. W. J. U. Sowter on bonding and earthing, recently published in our columns. He upholds the principle of bonding, but points out that there is great difficulty in providing a good earth so as to cause the fuse or circuit-breaker to act when a failure of insulation occurs. A plate buried in the ground is not, in his opinion, a good enough earth for large installations. He suggests the use of a safety device consisting of two metal plates separated by a mica disc between the outer of the concentric system and the earth wire connected to the transformer at the end of the feeder. If the pressure across the plates rises above a certain amount owing to the failure of the transformer, the gap is bridged, and the outer of the system is used as a return path, causing a complete short circuit. Mr. Partridge concludes with a warning with regard to the use of series transformers. (Page 717.)

We are able to publish some correspondence relating to a remark in a recent discussion as to the steadiness of the supply for textile mill-driving from the electricity works of the Manchester Corporation. (Page 718.)

The following books are reviewed in this issue:—"Theory and Calculation on Transient Electric Phenomena and Oscillations," by C. P. Steinmetz; "The Commercial Engineer's Pocket-book," by F. H. Davies; and "Der Betrieb Elektrischer Licht- und Kraftanlagen," by H. Pohl. (Page 719.)

The arrangements being made for the supply of electricity in Paris are described. It is the intention eventually to erect two large stations, one in the north and one in the south of Paris. The undertakings of the original "secteurs," which are now absorbed by a new company, are being linked up. Some of the smaller generating stations are being shut down and new substations established. Continuous current at 110 volts on the three- and five-wire systems is distributed in the more central districts, and single- and two-phase alternating current in the more outlying parts. A great part of the supply will be from the St. Denis station for the present. (Page 719.)

Some notes are given on the electric rolling stock now in use on the Lancashire and Yorkshire Railway. The newest cars are controlled by a multiple-unit system, in

Digitized by Google

which the return current from one of the motors actuates contactors for the remaining motors.. (Page 720.)

THE reports of H.M. Inspectors of Mines for the various districts contain a number of references to electrical working in mines, including statistics relating to the number of electrical coal-cutters employed and the results of inquiries into various fatal and non-fatal accidents connected with electrical mining installations. (Page 721.)

AN improved lifeguard for tramcars, the invention of Messrs. W. R. Bruce and F. Coutts, of the Paisley District Tramways Co., has been in use in Paisley for several months. The feeler can trail to any extent without tripping the guard or damaging the gear, and it is claimed to have a remarkably easy action without being affected by wind. (Page 723.)

AN explosion of gas and coal-dust in a seam of the Ferniegair Colliery, Hamilton, Scotland, resulted in the death of three men who were engaged at the time in fitting an additional length of trailing cable to an electric coal-cutter with the aid of a plug and socket connector. This was being done without first disconnecting the cable from the supply. (Page 723.)

SOME experiments have recently been conducted in short-distance wireless telegraphy, using a motor-car ignition coil. (Page 724.)

A NUMBER of amendments will be moved on the third reading in the House of Commons of the Electric Lighting Acts (Amendment) Bill. For the most part these aim at restoring the Bill to the condition in which it left the House of Lords by re-inserting clauses and words struck out by Standing Committee C of the House of Commons. (Page 724.)

NEGOTIATIONS are nearly completed for the establishment of four trunk telephone lines between France and Spain, which, when linked up with the Paris system, will enable speech to be transmitted from London to Madrid. (Page 724.)

THE adoption of the railless system of electric traction is under consideration in Madras. Experimental trials of the system are about to commence at Hendon. (Page 725.)

WE give some particulars of the electrical equipment of the collieries and works of the Florence and Stafford Coal and Iron Companies. In the collieries of the former company, where continuous current is used, over 90 per cent. of the coal output is mined by electrical coal-cutters. An abstract of a Paper by J. Paul, in which the electric power system of the Lochgelly Iron and Coal Co., Fifeshire, is described, is also given. (Page 721.)

AN agreement has been entered into between the Electrical Contractors' Association and Messrs. Simplex Conduits, Ltd., whereby, in cases of goods sold direct to the public at list price, half the difference between the list and trade prices will be paid to a contractor responsible for the introduction if he can be traced, or to the funds of the Association if no such contractor can be found. The Association, on their part, promise to give preference to the company's goods, but reserve the right to enter into similar agreements with other firms. (Page 726.)

A PATENT taken out by the Allgemeine Elektricitäts Ges. covers a process for absorbing the oxides of nitrogen, produced by the action of the electric discharge, by passing the treated air through apparatus containing oxides of zinc or copper, which give off the oxides of nitrogen on being heated. Among the other specifications published by the Patent Office on Thursday were two by C. Frenzen and F. R. Pope. The first describes the manufacture of titanium filaments, and the second is for a squirting process, in which the filament composition is squirted in a liquid state into a bath of alcohol, which hardens it immediately. The stopping up of the dies is said to be avoided by this process. Three specifications by J. S. Peck relate to the automatic switching gear for transformer distribution stations, manufactured by the British Westinghouse Co.; and one by J. & T. M. Greeves, Ltd., and R. V. Eves covers a driving gear for spinning frames. Bertram and E. Thomas have protected a method of preventing the heating up of the main contacts and bodies of tubular fuses by inserting heat-radiating strips or vanes between the fuse and the contacts. Two patents relating to telegraphic printing apparatus expire during the current week after their full term of life. (Page 727.)

BRADFORD electricity accounts for last year show a profit of £2,146.—A net profit of £4,169 is shown by the accounts of the Burnley Electricity Department for the past year.—The new Home Office Regulations regarding the use of electricity in factories will necessitate some rather extensive alterations to sub-stations in Hastings.—A net profit of £6,925 is shown by the St. Pancras electricity accounts.—Extensions to the Leith and Musselburgh tramway systems have been opened.—The Ipswich electric lighting accounts for the past year show a loss of £351, and the tramway accounts a loss of £2,294. (Page 728.)

BATTERSEA Council require direct-current motors and arc lamps; Rhyl Corporation a 125-kw. Diesel engine generating set and a 50-kw. steam generating set; East Ham Council have received sanction to borrow £1,836; Leyton Council require public electric lighting lanterns and clockwork attachments; a new generating set is to be installed at Todmorden; Kettering Corporation propose to borrow £2,000, and Warrington £500. (Page 729.)

YORKSHIRE Electric Power Co.'s accounts for the June half-year show a net profit of £1,070; Baker Street & Waterloo Railway Co., £18,304; Great Northern, Piccadilly & Brompton Railway Co., £33,592; Charing Cross, Euston & Hampstead Railway Co., £18,813; and the Liverpool Overhead Railway Co., £7,696. (Page 730.)

Railway Electrification in Canada.—An American Consular report states that the electrification of the Grand Trunk Pacific, or National Transcontinental Railway, from the St. Lawrence River to Moncton, is now under the serious consideration of the railway company, the Dominion Government, and the New Brunswick Cabinet. Electrical engineers who have given the subject consideration declare the conditions to be entirely favourable. The distance between the St. Lawrence and Moncton is about 460 miles, and for a considerable part of the distance the road passes through dense forests of spruce and fir in lower Quebec and northern New Brunswick, as well as through the rich farming country along the upper St. John Valley. At the Grand Falls on the St. John River, 170 miles from the St. Lawrence and 160 miles from Moncton, is located water-power sufficient to develop electrical energy for working the whole road. At this point the river has a natural fall of about 130 ft. and a flow that it is estimated will be sufficient to furnish from 100,000 to 125,000 horse-power continuously.

Wireless Telegraphy.—*The Times* states that the French inter-ministerial commission on wireless telegraphy, of which M. Henri Poincaré is the president, has just drawn up a Bill prohibiting the employment of any radiotelegraphic apparatus on French territory or on board of any French vessel without State authorisation. Penalties of from one month to one year's imprisonment or of from £40 to £720 are proposed for any infringement of this rule. Heavy fines are to be imposed in the case of persons who have intercepted and divulged radiotelegraphic or radiotelephonic messages.

According to *The Times*, the Russian military department has just made successful trials with wireless telegraphy between St. Petersburg and Sevastopol, a distance of about 1,900 miles. Stations for effecting communication between the Ural mountains and the western frontiers of Russia are to be erected.

In answer to Mr. Rees in the House of Commons on Tuesday, the Master of Elibank stated that only a few wireless telegraph stations had been opened in India up to the present, and it was not known what further stations were contemplated. The stations now open were available for public as well as for official purposes. He would inquire whether any extensions were contemplated.

CORRESPONDENCE

BONDING AND EARTHING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have read an article in your issue of July 15th, by Mr. Wm. J. U. Sowter, on this very important question. I fully endorse all the writer says, but his diagram shows a fuse on the outer conductor, which is obviously a mistake, and one which might cause a serious accident if carried out in practice. The principle of bonding, if carried out systematically, is an excellent one, but the bonding of all joints and ducts laid in the street is a very difficult matter, especially if the work has been done some years before, and several branches are taken off the high-tension feeders. A joint carelessly made by a jointer who happens to cut back the lead and armouring too far, or allows a layer of compound to get between the iron box and the lead, may cause considerable trouble.

I quite agree with the principle of bonding, but the great difficulty is to provide sufficient means whereby the current can get back to the generator in sufficient quantities to cause the fuse or circuit-breaker to act when a failure of insulation occurs. It is the custom in most cases to make earth by means of a plate buried in the ground at the particular point required, or possibly by the use of a water pipe; but in very large installations I do not consider that this is sufficient, as the resistance of the earth round the actual point where it is connected is so high that it is possible to get very large differences of potential across a few feet of earth or flooring in the event of an accident, without causing the fuse to act.

From an extensive experience of over twenty years on extra-high-tension work, I have known cases of the high-pressure current charging up walls and floors to such a dangerous potential that men received shocks from one foot to another—in fact, from anything they touched in the sub-station. I remember quite well the case of a man in charge of a large sub-station, when the high-pressure current was making earth at this point, informing me that "the current threw him from one side of the station to the other, sparks coming out of him in every place, and finally threw him through the door, giving him the most severe shock of all as he left the station"—which, by the bye, had a concrete

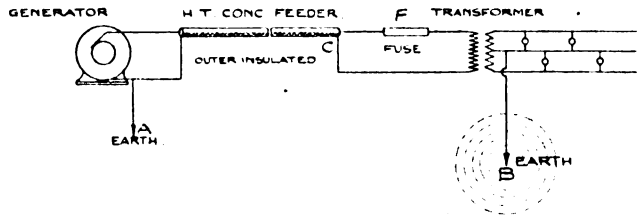

FIG. 1.—DIAGRAM SHOWING USUAL EARTHING CONNECTIONS FOR SINGLE-PHASE SYSTEM.

flooring. We all believed his story at the time to be more or less of a "fairy tale," and that there was a good deal of exaggeration in what the man said; but I made several experiments, and found that, although earth plates were quite satisfactory when dealing with small currents, they were quite inadequate when very large currents were flowing; and it was possible to get very high differences of potential between a few feet of earth near or about the point of contact with same, so I came to the conclusion that the man's story was more or less correct.

The diagram of Fig. 1 shows a single-phase generator, supplying a concentric system, with one pole earthed at the generating station only. The transformer is shown connected at the end of the high-tension feeder supplying a three-wire system with the neutral earthed. The case of the transformer itself will also, I presume, be earthed. Suppose, now, the transformer fails, the primary current will either get on to the case of the transformer, or on to the secondary winding, and be earthed by means of the earth plate *B*. Providing the transformer is a small one, say up to 50 kw., the current flowing through the earth between the points *A* and *B* will probably cause the fuse or circuit-breaker *F* to act and cut off the faulty transformer. If, however, the transformer is a 500-kw. size, the resistance of the earth round the point *B* will probably be so high that sufficient current cannot pass to cause the fuse or circuit-breaker *F* to act, more especially as they will probably be set to allow 100 per cent. increase of current to flow before acting. Under these circumstances, therefore, the generator keeps pumping current up the feeder through the fault, and the potential all round the earth plate is raised to a dangerous extent round the point *B*. What is wanted is some means whereby the current can flow back to the generator in sufficient quantity to cause the transformer fuse *F* to go, or the circuit-breaker, controlling this particular feeder, to act. This can easily be arranged for in this particular instance, by having a safety device connected between the outer of the concentric system and the earth wire, as shown in Fig. 2. It is not possible to earth both

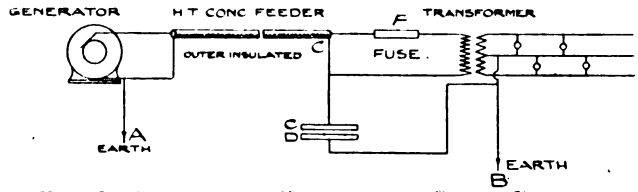

FIG. 2.—SINGLE-PHASE SYSTEM WITH SAFETY DEVICE AT TRANSFORMER END OF FEEDER.

ends of the outer conductor; or the safety device might be dispensed with. As soon as the potential between the plates *C* and *D* rises above (say) 500 volts, the current jumps across the air space between the plates, and the outer of the concentric system is used for the current to flow back to the generating station, causing a complete short circuit and the fuse or circuit-breaker to act at once. Safety devices, as shown, can be made at the cost of a few shillings by two metal plates separated by a mica disc perforated with a few holes. I have always insisted on this arrangement being carried out in all large installations connected to the London Company's system.

A few weeks ago, owing to a series transformer failing and going to earth, a safety device at a sub-station, set to act at 1,000 volts, was found to be fused up solid after the fault occurred, in spite of every precaution having been taken to ensure a proper earth connection being made to the whole of the earthed gear in the sub-station. Had no such arrangement been installed, I am convinced that a serious accident might have occurred, as in this particular instance there was nothing between the faulty instrument transformer and the oil switch controlling the feeder at the generating station, which acted instantaneously and cut off the faulty apparatus.

Speaking of series transformers, I would particularly warn engineers against the indiscriminate use of these transformers, which have been the cause of many very serious "shut-downs" to generating stations during the last few years; and it appears to be impossible to provide means for automatically cutting them out in case of failure.

In the case of a two-phase supply system, a similar arrangement as I have described might be used on each phase. In the case of a three-phase supply, if all three phases were brought into the sub-station, I

D

Digitized by Google

see no other alternative but to rely on the bonding of the sheathing and lead of the cables to ensure a complete metallic return to the generating station. In many cases in three-phase systems a special outer conductor is used outside the three cores, which makes the case very much simpler and safer, as shown in Fig. 3, where the safety device is connected between

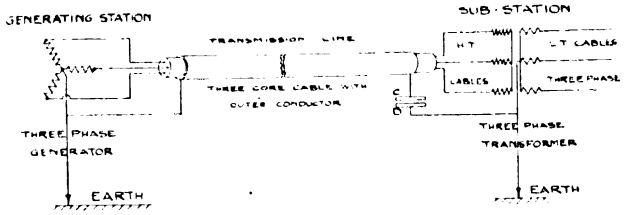

Fig. 3.—Three-phase System with Safety Device at Transformer End of Feeder.

the earth at the sub-station and the outer conductor, so that a proper path for the current is provided directly connected to the generating station, quite independent of all outside bonding, &c.

I must apologise for taking up so much of your valuable space, but the matter is an important one.

Yours faithfully,
G. W. Partridge, M.Inst.C.E.

The London Electric Supply Corporation.
London, August 6th, 1909.

ELECTRICAL DRIVING IN TEXTILE FACTORIES

It will have been noticed, from our report of the discussion on Mr. H. W. Wilson's Paper on "Electrical Driving in Textile Factories," read before the Institution of Mechanical Engineers at Liverpool (page 700 of our last issue) that Mr. A. Saxon spoke of complaints having been received of speed variation in the machinery driven by the Manchester Corporation supply system at the Bannerman mills. Mr. S. L. Pearce (Chief Electrical Engineer to the Corporation) has written us, stating that steps were immediately taken to contradict these remarks, and has kindly sent us copies of a letter which he wrote to Mr. Saxon, and also one to the editor of the *Manchester Guardian*, in which a similar report appeared. We give these letters below, together with the reply of Mr. Saxon to the *Manchester Guardian*, in which he virtually withdraws his remarks. We are glad to be able to publish these letters, which will help to counteract any bad impression that may have been created regarding the variableness of the supply for textile work from the Corporation mains.

Alfred Saxon, Esq., Manchester.

Dear Mr. Saxon,—My attention has been drawn to the report in the *Manchester Guardian* of the discussion on Mr. Wilson's Paper, in which you are represented as saying that "serious complaints have been made to the Electricity Department of the Corporation regarding the speed variation" on the machinery at the electrically-driven mill of the Bannerman Mills Co., in Bradford Road. This is not correct. The mill authorities are somewhat annoyed that such an unauthorised statement should have been made, which is one calculated to do substantial harm to the Electricity Department.

As considerable prominence has been given to the matter, I trust you will see your way clear to withdraw the statement.

I am,
Yours very truly,
(Signed) S. L. Pearce.

To the Editor of the "Manchester Guardian."

Dear Sir, In your account of the discussion on Mr. Wilson's Paper on the above subject read before the Institution of Mechanical Engineers at Liverpool last Wednesday, Mr. Saxon is reported as saying that "with regard to another so-called satisfactory example of electric driving, the Bannerman Mills, Manchester, the Corporation from whom current was obtained to drive the mill had received serious complaints about the speed variation."

As this statement, if allowed to go unchallenged, is one calculated to do considerable harm to the Electricity Department, I desire to contradict it, and am further authorised to say that the mill management are in every way completely satisfied with the electrical drive.

I am,
Yours faithfully,
(Signed) S. L. Pearce.
Chief Engineer.

To the Editor of the "Manchester Guardian."

Sir,—Your correspondent, in forwarding a condensed account of my remarks on the Paper on the "Electrical Driving of Textile Mills," published in your issue of Thursday last, has unintentionally misrepresented one portion of them. My remarks in reference to the Bannerman mills (and also another mill at Stalybridge), both of which are driven from power stations, where current is generated for both car traction and industrial purposes, were intended to show that there were difficulties in such cases, and at Stuart Street power station, from which the Bannerman mills receive their power, the chief engineer had found it advisable to instal a speed recorder to enable him to deal satisfactorily with any complaints he might receive.

Yours, &c.,
(Signed) Alfred Saxon.

Telephone Service for Pekin.—According to the *Daily Telegraph*, the contract for the establishment of a telephone service in Pekin has been awarded to the Western Electric Co. of America, the amount of whose tender was $150,000 (approximately £30,000). Tenders were submitted from practically all over the world, having first been invited two years ago.

The German Electrical Industry.—According to the *Elektrotechnischer Anzeiger*, the reports for the month of June, 1909, show that there was a slight increase in business in Germany with dynamos, motors, and accumulators over the previous months. No alteration in the work in telephone and telegraph shops was noticeable, but some improvement in the cable works and the insulation business was shown towards the end of the month. There was no shortage of labour. The lamp industry was slack, but the work in carbon factories was satisfactory considering the time of the year.

Electricity in Aeronautics.—The recently published interim report of the Army Advisory Committee for Aeronautics contained a programme of the research work to be undertaken at once at the National Physical Laboratory. Among the series of experiments included is one on the behaviour of different materials with reference to the accumulation of electrostatic charge, and generally as to the means of protecting airships from the effect of electrostatic discharges. The Executive Committee of the Laboratory have already made the necessary arrangements for carrying out this work.

Stuttgart Electricity Works.—The new water-power station of the Stuttgart municipality, which has been erected at Poppenweiler, at a total cost of over £100,000, has now been at work for some time. This station contains four Francis turbines of 575 max. h.p. each, and is the sixth generating station for the supply of Stuttgart, the others being an 800 h.p. water-power station at Marbach, a combined water-power and steam station at Unterturkheim with 600 h.p. water-power and 800 h.p. steam, and three steam stations of 3,000 h.p. each, at Marienstrasse Stuttgart, Stöckach, and Münster respectively.

Transformer Design.—A highly mathematical Paper on the design of single phase transformers of the core and shell pattern has been accepted as an original communication for publication in the *Journal* of the Institution of Electrical Engineers. The author, Mr. A. R. Low, deduces from fundamental considerations a system of equations which he then proceeds to solve graphically and algebraically for particular cases. Rules for obtaining the dimensions of the most efficient transformer under given conditions are deduced, and an example of the design of a 50 k.v.a. transformer is worked through, and the losses evaluated. The Paper concludes with a useful bibliography.

REVIEWS OF BOOKS

Theory and Calculation on Transient Electric Phenomena and Oscillations. By Charles Proteus Steinmetz. Pp. 544. 9½ in. by 7½ in. 102 illustrations. (New York: McGraw Publishing Co.) $5.

This book is one which contains a mine of information on some of the more transient effects which occur in an electric circuit. It deals with a number of phenomena which, although they have been recognised as having an existence, have not hitherto received any adequate theoretical treatment. The opening chapters deal with the constants of an electric circuit, its resistance, inductance, and capacity. (One of the most interesting calculations in this section is that relating to the building up of voltage in a self-excited shunt-wound generator.) A study of these constants separately, naturally leads to the discussion of electric oscillations; and in this connection particular stress is laid on the transient term, a term which is nearly always neglected in the study of electrical engineering problems. The phenomena which occur when a long transmission line is switched off and on, are dealt with in detail, and the results should be of very great value, not only from the scientific standpoint, but from the point of view of the practical engineer.

One of the most valuable chapters in this section of the book is that dealing with low-frequency surges in high-potential systems. The conclusions arrived at are most important; it is shown that the only dangerous oscillations likely to take place in a transmission system are those which occur when the line circuit is opened under load, or when a short circuit is interrupted. Incidentally this chapter emphasises the advantage of the oil break switch, as it shows that these phenomena are least likely to be dangerous when the circuit is opened near the instant of zero current, a condition which is known to occur when a circuit is broken under oil.

In the chapter on "Mutual Inductance" there is a novel and interesting application to the building up of voltage in an over-compounded direct-current generator, with an immediate application to the automatic booster and a study of the quickness with which such a machine can follow sudden variations of load.

The chapter on magnetic saturation and hysteresis is full of interesting deductions as to the behaviour of a transformer when it is switched into circuit, and the possibilities of heavy current rushes are clearly indicated. In the chapter on the "Short Circuiting of Alternators" there are some most interesting oscillograms of the short-circuit currents in turbo-alternators in addition to a great deal of theoretical work.

The second section of the book deals with periodic transient phenomena, such as occur in rectifiers of all kinds; the section deals with the theory of mechanical rectifiers and arc rectifiers, and is also illustrated by oscillograph records.

The third section deals with what are called transient phenomena in space, that is, phenomena which are not instantaneous with regard to time (but which may be periodic), such as the relation between current and potential difference at the two ends of a transmission line, or the currents at different points inside a conductor (such as a rail return) carrying single-phase current. In this section the use of complex quantities reduces several of the problems which would otherwise be almost insoluble to manageable dimensions, and free use is made of this powerful analysis.

The last section deals with the production of standing or stationary waves and travelling waves, and with free oscillations, such as occur in a circuit to "which neither energy is being supplied, nor from which energy is being abstracted." The most important practical case dealt with is that of the transmission line connected to step-up and step-down transformers on open circuit. The final chapters deal with reflection and refraction at a transition point and with inductive charges into a transmission line.

It is impossible to do justice in a short notice to this remarkable book; it is closely packed throughout with facts and theories of all kinds, and it abounds in practical illustrations. The book can only be compared with treatises, such as those Heaviside has produced; it has, however, an inimitable advantage over these works in that it uses a notation which is known to most electrical engineers. Another very important feature is the number of practical applications which have been worked out, and which make the meaning of the theoretical formulæ exceedingly clear. This book should prove a veritable classic to the electrical engineer.

The Commercial Engineer's Pocket Book: Electricity Supply: A Handbook for Publicity Department Managers, Electricity Supply and Contractors' Representatives. By F. H. Davies. 44 pp. 3¾ in. by 6¾ in. (London: Alabaster, Gatehouse & Co.) 1s. 6d.

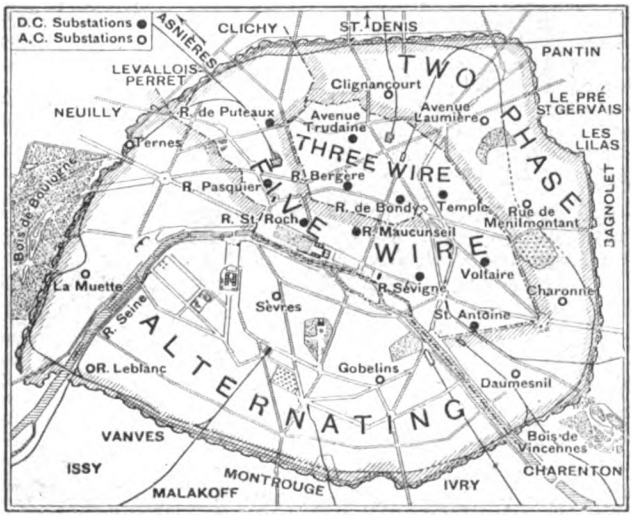
The handy little pocket book before us is something of a new departure, and should be of considerable use to a certain class of *non-technical* technical man, by which contradictory expressions we mean a man whose commercial position requires an acquaintance with electricity supply matters, but not a skilled engineering knowledge. Representatives both of contracting firms and supply undertakings, for example, require to have complete comparative data of the capabilities of electricity and gas at their fingers' ends as well as a host of miscellaneous facts and figures to meet prospective consumers' arguments. Mr. F. H. Davies has provided this sort of information in a very convenient form, and has brought together a great deal of useful practical material, much of which would otherwise require some searching to find. A basis for comparison is provided as regards lighting, power, and heating and cooking, the last-mentioned section in particular containing data which it is sometimes difficult to lay one's hand on.

Der Betrieb elektrischer Licht- und Kraftanlagen. By H. Pohl. (Bibliothek der gesamten Technik. Band 100.) 119 pp. 4½ in. by 6¾ in.; 89 illustrations. [Hanover: Max Jänecke.] 2.50 M.

Line drawings and descriptive matter relating to typical boilers, engines, and fittings are given in the first part, together with a large amount of useful information as to the care of steam, water and gas- or oil-engine plants, but the second part, which relates to electrical apparatus, is disappointing. A useful feature of the book is a short chapter on the keeping of accounts in small generating stations.

ELECTRICITY SUPPLY IN PARIS

Considerable changes are in progress in the arrangements for the supply of electricity in Paris, and an article in *Le Génie Civil* outlines the state of affairs. It will be remembered that in 1889 concessions were granted to six different companies, each having powers to supply a portion of the town known as a *Secteur*, and various systems of distribution were employed. At the expiration of these concessions in 1907, the Municipal Council of Paris drew up a new scheme arranged to fit in as much as possible with the existing conditions, as it was, of course, neither possible to clear away all the old installations nor the pre-existing financial organisations. Some of the conditions of the new scheme were given in an article in Electrical Engineering, Vol. I., page 950 (June 6th, 1907). A new company, called the Compagnie Parisienne de Distribution d'Electricité, is to take over the business of the existing secteur companies on Jan. 1st, 1914, and the concessions are extended to 1940. At this date, all the buildings, mains, machinery, and plant will become the property of the Municipality without payment. The companies have to pay the City initially a minimum of £120,000 a year as royalty; and this sum may be increased considerably, in accordance with a sliding scale, if the new company, which takes over the companies' concessions from 1914 to 1940 makes more than 6 per cent dividend. There are other stringent conditions, one of which refers to the constancy of pressure and frequency. Penalties may be enforced if the pressure varies 3 per cent. above or below 110 volts, or if the pressure at any particular point of the network rises or falls more than 1½ per cent. The same limits of variation of frequency are imposed.



The supply is to be eventually principally from two large stations, one in the north and the other in the south of Paris. Provisionally, that is to say, up to the end of 1913, the present networks are to be fed from the existing generating stations in the following way through a series of sub-stations in the positions shown in the accompanying plan. The town is divided into four zones or districts, two with continuous-current distribution and two with alternating-current distribution, and most of these are to be fed with alternating current, either single-phase at 3,000 volts, or three-phase at 12,300 volts 42 cycles.

The three-wire zone is made up of the former Edison Secteur and that of the Compagnie d'Eclairage et de Force; the five-wire zone is made up of the Secteurs Popp and Clichy; the single-phase zone comprises the original Champs Elysées and

Digitized by Google

Rive Gauche undertakings; and the fourth, or two-phase, zone includes the outlying suburbs to the north-east of Paris.

Some information as to the details of each zone is also given in *L'Industrie Électrique*. In the three-wire zone, which includes the boulevards between the Opéra and the Boulevard de Strasbourg, the numerous existing generating stations and sub-stations will be replaced by a new 10,000-kw. distributing centre in the Rue Bergère, which will be supplied from the large generating station at St. Denis of the Société d'Electricité de Paris at 10,000 volts, and will be equipped with synchronous motor-generators. The same system of distribution (2×110 volts) will be used in the neighbourhood of the Place de la République and the existing sub-station in the Rue de Bondy is to be re-equipped to bring its total capacity up from 2,000 to 9,000 kw. It will also be supplied from the St. Denis works, but at 12,300 volts two phase, and is being equipped with transformers and rotary converters. The old Edison generating station in the Avenue Trudaine will be converted into a sub-

PLAN OF PARIS, SHOWING THE DIFFERENT DISTRIBUTION ZONES AND THE POSITIONS OF THE PRESENT AND FUTURE SUB-STATIONS.

station, also supplied from St. Denis, and there are already installed four 500-kw. and three 1,200-kw. converting sets. The old station of the Société d'Eclairage et de Force at la Villette and a sub-station at the Gare du Nord will be shut down.

The five-wire zone is now supplied from the works of the Secteur de Clichy (Rue des Dames, aux Batignolles), and by a sub-station in the Rue de Puteaux equipped with rotary converters and transformers fed at 5,000 volts three-phase from the station of the Société "le Triphasé" at Asnières. A similar sub-station is also to be established in the Rue Pasquier, near the Gare St. Lazare. The old Rue St. Roch sub-station of the Cie. Popp is to be increased in capacity from 2,500 kw., first to 6,000 kw. and later to 12,000 kw.; motor-generator sets will convert from 12,000 volts three-phase to 4×110 volt continuous current. The Rue de Sévigné sub-station of the same company will be enlarged in like manner to deal with 10,800 kw. A sub-station in the Rue Mauconseil will take up the old municipal station of the Halles. This will be supplied from St. Denis at 12,000 volts, and the initial equipment of six 1,000-kw. rotary converters will later be increased to 12,000 kw. Further rotary converter sub-stations in this zone, fed from St. Denis, will be that named Voltaire in the Avenue Parmentier (3,000 and later 9,000 kw.), the Temple sub-station in Rue Corbeau (2,400 and later 7,800 kw.), and the St. Antoine sub-station in Rue des Charbonniers and Rue Charenton (3,000 and later 9,000 kw.).

The single-phase alternating zone was fed partly by the original station of the Secteur des Champs Elysées at Levallois-Perret, but the output of this station, which is less than 6,000 kw., is insufficient for future needs, as the demand in this district in 1913 is estimated at 10,000 to 12,000 kw. It will therefore be replaced by two sub-stations, one at la Muette (Rue Pajou) and the other at Ternes, equipped respectively with six and four 1,200-kw. static transformers, and supplied from St. Denis. The 7,000-kw. station of the Secteur de la Rive Gauche at Issy-les-Moulineaux is also too small, and it will be reinforced by similar transformer sub-stations, one in the Rue de Sèvres, and the other, known as the Gobelins sub-station, in Rue Vésale.

The two-phase zone is situated in the region north of the outer boulevards, and is fed at 110 volts two-phase by transformer sub-stations supplied at 12,000 volts from St. Denis. There will be in all forty transformer points, with automatic switchgear connected to five main distributing transformer sub-stations at Clignancourt, Laumière, Menilmontant, Charonne, and Daumesnil, which are now under construction.

The scheme also involves the construction of extensive subways under the streets for the accommodation of the new trunk mains and feeders. The first part to be undertaken will be subways some 2¾ miles in length for the interconnecting cables between the Saint-Roch and Pasquier sub-stations, the Trudaine and Puteaux sub-stations, and the Puteaux and Pasquier sub-stations respectively. The cost of these will be about £40,000, but considerable economy will be effected in the laying and attending to these and future cables.

Pending the completion of the two large new generating stations, a great part of the supply will, as we have seen, be given, especially as regards the right bank of the Seine, from St. Denis, connected by direct feeders to the Trudaine, Bondy, Bergère, Mauconseil, Saint-Roch, Sévigné, and la Muette sub-stations. The whole work of conversion will occupy a considerable time, and has, of course, to be carried out without any interruption in the supply. The alterations will be effected gradually to keep pace with the increasing demand.

ELECTRIC ROLLING STOCK ON THE LANCASHIRE AND YORKSHIRE RAILWAY

SOME particulars of the latest electric rolling stock in use on the Liverpool–Southport Section of the Lancashire and Yorkshire Railway are given in the *Railway Gazette* in connection with the inspection of the line by the members of the Institution of Mechanical Engineers.

The rolling stock consists of 50 standard motor cars, 2 baggage cars, 12 multiple unit motor cars of smaller type, 58 trailer cars, and 12 multiple unit cars of the standard type. The trains, normally, are composed of 3, 4, and 5 cars, with 2 motor cars in each case to suit the traffic requirements. Each standard motor car is equipped with four motors; each motor is capable of carrying a starting current of 300 amperes for a short period and is rated at 150 b.h.p. The gear ratio is 43/22, and the diameter of the car wheels is 42 in.

The standard direct control motor cars are single ended, and the multiple unit are double ended. At the driving end of the direct control cars a large controller with two barrels deals with the current for both motor cars. As the resistances on the leading motor cars serve for both motor cars, only four train cables are necessary. Each car is protected when running by an automatic circuit breaker of 2,000 amperes capacity, the circuit breakers for both cars being in the motorman's cab at the leading end of the train.

The vacuum brake is used, the vacuum being produced by an electrically-driven air pump. The vacuum is also used to sound the horn. For through services over the Liverpool Overhead Railway and other extensions several new cars have been built; these cars are equipped with two motors of 125 h.p. The motors are controlled by a multiple unit system, in which the return current from one of the motors operates contactors for the remaining motors.

The following details of weights and other particulars are of interest:—

	Tons.	Cwt.
Weight of one standard motor car with four 150 h.p. motors (unloaded)	45	10
Weight of one trailer car complete	26	2
Weight of one 150 h.p. motor complete with gear ...	2	16
Weight of one motor bogie with two 150 h.p. motors, complete with electrical equipment	11	19
Total weight of electrical equipment in car body of standard motor cars	3	0
Weight of one contact shoe	64 lbs.	
Average number of trains in service	18	
Maximum momentary current per train (amperes) ...	2,400	
Average current per train, at full speed (amperes) ...	550	
Train-miles per day	4,300	

Water-power in Canada.—A report was prepared for the purposes of the North American Conservation Conference, on the water-power of Canada, by Mr. J. B. Challies, of the Department of the Interior. The minimum flow development of all the water-power of Canada is estimated at over 25,680,000 h.p., of which about 516,900 has as yet been developed. The total amount is distributed approximately as follows:—Quebec, 17,075,000 h.p., of which only 50,000 h.p. is utilised at present; Ontario, 3,129,000, of which over 331,000 h.p. is utilised; British Columbia, 2,065,000 h.p., of which 73,100 h.p. is utilised; Alberta, 1,144,000 h.p., of which 1,330 is utilised; and the remainder divided fairly equally (about 500,000 h.p. each) between Yukon, Saskatchewan, Manitoba, North-West Territories, and New Brunswick, with the exception of 54,300 h.p. in Nova Scotia, of which 13,300 is already utilised. The largest single fall in the country is that of Hamilton River, in the Labrador peninsula, with a possible development of 9,000,000 h.p. The Niagara Falls come second, but a treaty between the United States and Great Britain imposing a limit on the extent to which this water-power is to be utilised is now awaiting ratification.

ELECTRICITY IN MINES

Report of H.M. Inspectors of Mines

THE annual reports of H.M. Inspectors of Mines for the various colliery districts contain each year an increasing number of references to electrical working as the use of electricity in mining becomes more general, and throw some light upon the directions in which electrical mining engineering is developing, and experience regarding its safe application. It is, of course, the main object of the inspector to consider safety, so that, naturally, a large part of the reports is devoted to inquiry into the circumstances of accidents. An extensive digest of the collected reports is given in the *Colliery Guardian*, from which we have abstracted the information relating to electrical working given below, taking the various districts separately. In a few cases extracts from the reports and accounts of accidents have already appeared in our columns, but for the sake of convenience we deal with all the districts below, even where slight repetition is involved.

Mr. R. McLaren's report for the East Scotland district gives, amongst his comparative statistics relating to coal-cutting machines, figures which show that during the year under review 2,112,594 tons of coal have been cut by the 195 electric machines, as against 743,902 by compressed air machines numbering 93. Two fatal accidents due to electricity are recorded. The first accident occurred at Dysart Colliery, Fife. A triple concentric cable was placed in a wooden box filled with bitumen, laid on one side of the haulage roadway. At one part of the roadway water dripped from the roof, and in order to protect the box deceased was instructed to lay corrugated iron sheets on the top, and to fix them by tying. Instead, however, of tying, he drove a nail into the box, which passed in through to the cable, and reaching one of the box wires caused the iron sheet to become live. His left hand rested on the sheet while he drove in the nail, and current passing through his body to earth, he received a fatal shock. The voltage was 250. The second case took place in Aitken Colliery, Fife. Electric lighting wires were taken from main cables, which had previously been in use to work a motor, and part of a haulage way was lighted. A number of men were making some repairs on the roadway when a small stone fell away from the side and threw down the lighting wires. Two of the men lifted the wires, and while tying them up temporarily one man's body came in contact with a live part, causing a fatal shock. An examination afterwards was made, and it was found that the wire had been broken, the wires joined together by twisting, and the bare part covered by a piece of string. This piece of string was wet and acted as a conductor, and it was this part which came in contact with deceased's naked body. Evidence could not be obtained as to who twisted the wires, but it was quite evident the work was done by a novice, in contravention of the Electrical Special Rules. A short distance out-bye was a switch which was easily accessible, and had it been used to cut off the current before interfering with the wires, no accident would have happened. The voltage was 450.

A curious case of men underground receiving severe shocks through the pithead gear being struck by lightning is recorded. The inspector emphasises the importance of fitting efficient lightning conductors to all head-gear.

In the West Scotland district Mr. Ronaldson also reports that electric coal-cutters are much more used than compressed air. 1,356,162 tons of coal were cut by 146 electric machines against 6,991 by 76 compressed air cutters. One man was reported to have been killed by an electric shock at Tannockside, No. 3 Pit, Lanarkshire, but after careful examination of the circumstances, there is some uncertainty as to whether he did not die from natural causes, as Mr. Nelson (H.M. Electrical Inspector of Mines) was unable to find any defect which could have caused the cable to have become live. Mr. Ronaldson remarks that there was one non-fatal accident from an electric shock which was not reported, as should have been done, and this took place in Home Farm Colliery, Lanarkshire. A brusher was handling the trailing cable of a coal-cutting machine, and while doing so got a shock which was caused by the insulation having worn off. There is, he continues, a tendency among some officials to disregard the regulations which are so necessary to prevent shocks from cables with defective insulation, and it is not unusual to see cables below ground placed in positions that invite the destruction of insulating material.

From Mr. J. B. Atkinson's report on the Newcastle district it appears that electrical coal-cutters are less numerous than those driven by compressed air, numbering 42, which have cut 480,415 tons against 145 of the latter, which cut 629,150 tons. No electrical accidents are mentioned.

In the Durham district, Mr. Bain reports the use of 72 electrical coal-cutters against 103 worked by compressed air; the amount of coal cut by the electrical machine, however, was considerably more, being 700,166 tons against 250,978 cut by compressed air. There was only one accident, and that non-fatal, from electricity underground. A coal-cutting machine man received a shock when switching the current on to a coal-cutter. The explanation appeared to be that the man, in starting the machine, did not put the switch right over; an arc was formed and it burned out the insulating material, thus causing the machine to be alive.

In the Yorkshire and Lincolnshire Districts, compressed air machines are also in a slight majority, numbering 159, as against 111 worked by compressed air. The tons of coal cut in each case were 1,669,852 and 1,116,319 respectively. An ignition of gas was reported in an engine-room of an intake haulage road at Soothill Wood Colliery, by a flash from the starting switch of an electric motor. The motor had been fixed for hauling up an incline which had crossed a downthrow fault. The room was ventilated with fresh air, but gas was found in it after the accident. The inspector in this district (Mr. Pickering) is not altogether in favour of electrical working in fiery mines.

In the report on the Manchester and Ireland Districts by Mr. Gerrard, 16 electrical cutters, which cut 100,261 tons of coal, and 81 compressed air machines, which cut 196,551 tons, are reported for Lancashire, and one electric coal-cutter for Ireland. A fire due to a damaged electric cable is reported at Hulton. No one was in the mine, and about 4 p.m. the attendant in the power house noticed the needle of an ammeter on the switchboard agitated, then the fuse blew; he saw that the needle of another ammeter connected with an upper seam was agitated, and promptly switched this circuit off. On going to the door of the power-house, looking in the direction of the upcast shaft he saw volumes of smoke coming out of the shaft, and raised an alarm. Descending the downcast shaft, it was found that a fire was raging in the return. Fortunately, water pipes laid on to water the roadways in connection with coal-dust enabled water under considerable pressure to be used, but it took two days and nights continuous fighting to subdue the fire. An electric cable was carried down the upcast shaft along the return for 20 yards, and then through an air crossing into the main intake. Every inch of the cable in that 20 yards was carefully examined, and a place was found where the cable was severed; at that point both ends of the severed cable were found to be fused, the copper, the insulation, the armouring being melted together. By measuring the severed length from the air crossing to the point of fusion it was seen that this point was at a place where there was a fault in the strata, and at this point the roof was supported by steel girders. In Mr. Gerrard's opinion a fall occurred from the fault side, displacing a girder and carrying the cable down to the floor. The girder so crushed the cable that a short circuit was established, although the space of time which elapsed before the fuse blew was short it was sufficient from the intensity of the electric flame to melt the parts of the cable and establish the fire.

Mr. H. Hall, in reporting on the Liverpool and North Wales colliery district, speaks of the provisions of the Miners' Eight Hours' Bill, and considers that the increased use of mechanical coal cutters will assist in maintaining the output of the mines.

A workman was killed by an electric shock from a 500-volt circuit at the Bispham Hall Colliery, near Wigan. Mr. G. S. Ram, H.M. Electrical Inspector of Factories, examined the installation, and gave evidence at the inquest. He said he considered it was quite wrong to have fuses on switches on the outer conductor in such a system as that; in fact, the rules he was acquainted with strictly forbade it. It appeared, however, that Mr. Woods and Mr. Marsden had somewhat been misled by Rule 9, which specified the conditions under the ordinary system. The concentric system was a special system, for which special precautions had to be taken. Mr. Woods appeared to have been careful in providing a special earth connection in addition to the one at the generating station. But one of the fuses which they had, ought not to have been there at all. If the earth connection had been in order the accident would not have happened. If there had been no fuse at all it would have been quite unnecessary to have another earth connection. Then there was another important point, if they were to have the concentric system in the mine at all, it should be concentric throughout. The deceased man was travelling up a steep inclined road on his way home; on one side of this road the cable was suspended carrying electricity into the mine; he used the cable to help himself along, and, in doing so, touched a part which had been damaged in some way so as to destroy the insulation. This damage ought to have been discovered and repaired; the earth connection was also out of repair. Mr. Hall finds that the electric installations at the mines are not carried out so as to ensure the maximum

Digitized by Google

degree of safety. In the power-house or generating station on the surface no expense is spared, and the fittings are generally of a high class, and the work well done, but this is by no means always the case in the distribution of the current underground. Electrical machinery is dumped down into motor-houses, where the space is so restricted that the attendant cannot move about without constantly coming into contact with the cables; it is true these cables are supposed to be insulated, but this is no excuse for their being left hanging loose or fixed in such positions that the attendant may accidentally fall over them or entangle himself among them. Mr. Hall says he has observed that electricians seem to treat with contempt any suggestion of danger from shock, and they forget that the class of person who are made into attendants in these places cannot and do not realise the imminent risk there is, should the cables become frayed or worn so as to expose the tiniest bit of metal conductor, or should any of the numerous joints of the cable go wrong. Of these latter joints he found as many as a dozen in a small motor-house, more than half of which were quite unnecessary.

The report of Mr. A. H. Stokes, for the Midland district, gives 91 as the number of electrical coal-cutters, against 82 worked by compressed air. 982.269 tons of coal were cut electrically and 845.058 tons by compressed air.

It cannot be said, continues the inspector, that coal-cutting machinery is making successful headway in the district, and although the holing or undercutting of coal is laborious work, not unattended with danger, yet few mines will avail themselves of mechanical machines to do the work. The initial outlay for driving power and the maintenance of the machines are matters for serious consideration, so much so, that managers are reluctant to incur a doubtful expenditure in experimenting with coal-cutting machinery.

Two fatal accidents were caused by electricity. In one of these the accident occurred at a small 550-volt continuous-current motor used for haulage for a deep heading. The deceased was found lying on the floor between the motor and the switchboard. There were three incandescent electric lamps burning, and the motor-house was well lighted. The previous motor driver had only left the place a few minutes, and he declared that the switch and controller were off when he left the motor. Both the switch and controller were off when deceased was found. The floor was of wood, but damp, and so were the trousers and feet of the deceased. The installation was unsatisfactory, for one of the terminals was bare and so near the handle of the switch that, unless great care was taken, the hand of the person working it was liable to come in contact with the live terminal. This was probably the explanation of the way deceased received the electric shock. In the other case deceased was in charge of the hauling arrangements at the junction of two roads, and from this junction to the haulage motor the signals are given by electricity from a battery in the usual form for signalling; running parallel, and for a short distance near together were two power cables, taking current to a pump some distance from the junction. Deceased was seen to be examining the signal bell, which was sparking badly, and a blue flame playing round it. Soon afterwards he was heard to cry out, and, upon some workmen going to him, they found the lower bell wire under his left arm-pit. The colliery electrician found that part of the bell had been burnt off, and going further along the roadway found a place 150 yards away where there appeared to have been a contact between one of the cables and one of the signal wires. The signal wire showed signs of contact with a bare place in the power cable, but they were some distance apart. Some repairers were at work a few yards below the place where the contact occurred, and it is probable that their work had in some way interfered with the position of the signal wires and the power cable, and so brought them temporarily together. The power cable was carrying continuous current at 500 volts. Four non-fatal electrical accidents have occurred during the year. The driver of a haulage motor when finishing his day's work sent a youth to draw up a train of tubs, and this youth left the controller upon the first contact with the switch in contact and the brake on the haulage drum pegged down tight, the result being that the resistances heated and were burned, and the side of the motor-house, which was cut out of the solid coal, caught fire. It was not discovered until some time afterwards, when the fire was quickly put out. A haulage motor driver was slightly burned on the hand, and in explanation stated that when putting the switch in with his left hand he got his wrist on the terminal of the pole. More probably he was doing his work carelessly, and a flash occurred at the poles of the switch. Another haulage motor driver received a shock when hauling a train of tubs. The motor is fitted with a tramway-type controller, and after the accident it was found that the contacts of the controller were burned off. It was probably due to carelessness in passing the dead stop slot with the controlling and going on to reverse the load. He had been previously warned by the electrician not to do this. In one case the fusing of a switch and the burning of the motor driver's hand occurred at a motor used for driving a screening plant. It was probably due either to putting in the switch, which is the first duty, and the controller at the same time, or the controller was on at the same time he put the switch in. A colliery mechanic was holding a portable electric light while some fitters were at work repairing a pump. He fell and broke the lamp, receiving a shock from the projecting wires being in contact with the lamp holder. A driver was taking two empty tubs with a pony into a working place, when he found that a piece of roof had fallen and broken down the electric cable taking power to the coal-cutters. The pony's gear caught in the cable, and in pulling to get free the gear abraded the covering and bared the wire. The current at 350 volts killed the pony, and the driver and another man received shocks.

In speaking of electrical working in mines generally, the report continues, "there appears to be a disposition on the part of many owners and managers to adopt or extend the use of electricity as a motive power. One reason for the tendency is no doubt the facility with which the power can be carried, or transported from place to place, and the expeditious erection of the plant. There is economic advantage in this, provided that it is well designed with a due regard to the question of load, but many plants have been erected with very meagre, if any, provision for surplus power, more especially those designed for haulage purposes, where little consideration has been given to inertia, or the extra power required in the first few moments when starting to run after standing for a week-end. To those electricians who have not yet experienced difficulty with underground motors a timely warning may save them disaster and disappointment at some future date."

Mr. H. Johnstone's report for the Stafford district gives 19 electrical coal-cutters against 34 worked by compressed air. 315.845 tons of coal were cut electrically, and 119,741 by compressed air. No fatal accident due to electrical causes are mentioned, but a "dangerous occurrence" was reported, consisting of an ignition of insulating material on an underground electric cable, owing to the cable having been damaged and the insulation breaking down.

In the Cardiff district comparatively few coal-cutters are used; four are electrical and 12 driven by compressed air, the amount of coal cut by each being 28,493 tons and 73,529 tons respectively.

There were two accidents during the year through the use of electricity, by which one life was lost and one person injured slightly. The fatal accident occurred at Ferndale No. 1 Colliery at a haulage plant on the main level. The plant consists of a 200 B.H.P. motor of the slip-ring pattern with enclosed slip-rings, which works a pair of main and tail rope drums. The voltage was 2,200, and the current ran up to 50 amperes. Arcing had been noticed at the point where one of the three cables was attached to the stator coils of the motor, and the electrician who had charge of the haulage engines wrote a note to deceased telling him to re-make the joint during the night shift. Deceased and another electrician went to do so at 8 p.m. He put out the switch and laid everything dead, opened and re-made the joint by soldering it. It was then covered with insulating tape. The motor was worked soon after in deceased's presence, and no arcing was observed. About 2.30 a.m. he returned to the motor room. He saw the motor was idle, with the controller on the "off," and he, without knocking out the switch, which he passed, went and sat on the iron bedplate, and put his hand on the joint to see if it was cold, and received a fatal shock. Only two phases were made dead by putting the controller in the "off" position; the third remained alive. This fact deceased appears to have forgotten, or he may have thought the insulation he had put on the joint was sufficient protection. The motor was properly earthed, and an automatic switch was provided by which the current could be cut off the motor. On April 29th, at Penallta Colliery, a fuse on the high-pressure side of a transformer in a lodge room blew, and the lights at the sinking pit bottom went out. Instead of sending for the electrician, as he had been instructed, the leading sinker tried to renew the fuse, and in doing so caused an arc, which burned his face slightly. The electrician on being sent for found that the current had not been switched off. It was fortunate he had indiarubber gloves on, and that he was standing on a rubber mat. The voltage was 3,000.

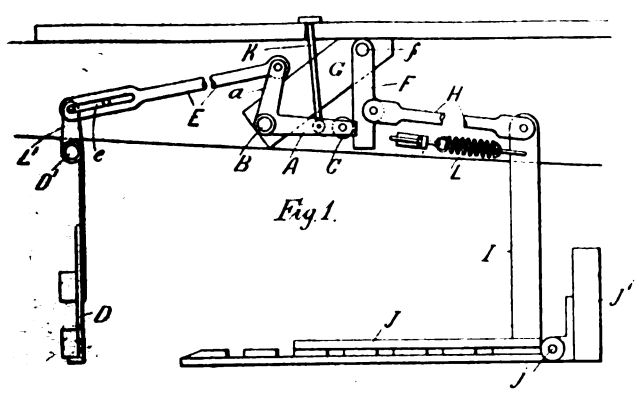
In the Swansea district, Mr. J. Dyer Lewis records the use of 10 electrical coal-cutters and 5 worked by compressed air. 75.606 tons were cut electrically, and 22.210 tons by the compressed-air machines. No electrically caused accidents are mentioned.

Mr. J. S. Martin, in his report on the southern district, states that the 12 electrical coal-cutters in use have cut 35,410 tons of coal, as against 60,320 tons cut by 19 compressed-air machines.

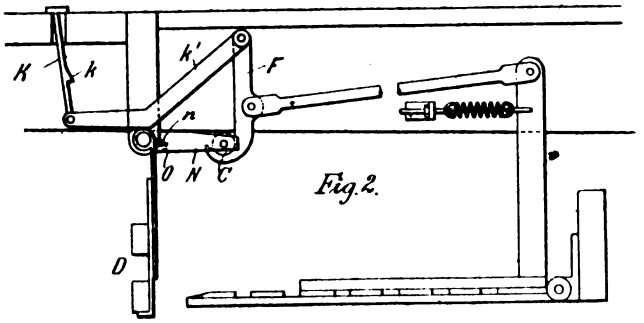
A fatal accident occurred from the use of electricity at Bargoed Colliery. The deceased was an electrician, and was called to the underground haulage engine owing to a defect. He was in the act of examining the controller for the third time for a latent defect, which was afterwards found by testing, when, in some accidental manner, he made contact with live parts and received a fatal shock. Current had not been cut off as was done on each previous occasion of taking out the controller, and as he no doubt expected the lad in charge of the engine had done.

There was also a fatal accident by electricity on the surface.

Digitized by Google



A man was painting in a house containing a 5 horse-power motor, and apparently touched a bare terminal and received a current through him which caused his death. The machinery and electrical arrangements were all enclosed, and he had no business to interfere with them.



The inspector remarks that rapid strides are being made in the adoption of electricity in the mines throughout the district in Cornwall, Gloucestershire (Bristol and the Forest of Dean), Kent, Monmouthshire, and Somersetshire. It is used for pumping, underground haulage, and the working of coal-cutters.

AN IMPROVED TRAMCAR LIFEGUARD

A LIFEGUARD having some novel features has been invented by Messrs. W. R. Bruce and F. Coutts, Rolling Stock Superintendent, and Engineer and General Manager, respectively, for the Paisley District Tramways Company, and is being placed on the market.

The accompanying figures, which are reproduced direct from the drawings accompanying the patent specification, show diagrammatically two different types of the guard, and are almost self-explanatory. In the type shown in Fig. 2, the action of the guard is brought about by a roller *C*, running on the edge of a link *F*, which is connected to a lever and an arm attached to the tray of the lifeguard towards its lower end. The roller is carried by a lever *N*, which is pivoted on the spindle from which the gate of the lifeguard *D* is suspended. When the tray is in a raised position, the roller falls to a position slightly below the horizontal. This

TWO TYPES OF THE BRUCE AND COUTTS IMPROVED TRAMCAR LIFEGUARD.

gives the lifeguard a tendency to re-set itself if the feeler is only moved through a short distance, as might be caused by a gust of wind or the oscillating of the car. The feeler is able to trail to any extent without tripping the guard or damaging itself or the mechanism. This feature is due to the action of a cam *O*, which strikes the pin *n* and actuates the lever *N* only when the feeler is struck by an object in front. This prevents its being damaged also when a car is reaching a terminus with a lot of passengers, the great majority of whom crowd on the platform and stairs to try and get off at the earliest moment, and thus bring the back of the car a few inches lower than is usual in running.

The mechanism which lowers the tray is claimed to be so easy in its action that the smallest and lightest obstacle passing underneath the feeler instantly drops the tray. When once dropped, it cannot rise until it is re-set by the motorman, thus preventing by any chance an obstacle getting partly rolled underneath it. An additional claim is that the wind has little or no effect on it, and Mr. Coutts informs us that in the nine months during which he has had four cars running with it, he has not had a single case where the wind has been the means of dropping the guard. The guard has, we are told, given every satisfaction, and the upkeep has proved to be negligible. Patents covering the device have been taken out in this country, in the United States, and in the British colonies.

This lifeguard can also be arranged with a stirrup in place of a flat-headed pin, which construction enables the motorman to drop the lifeguard should he have time to do so. It is also designed with the feeler well in front of the replacing pin or stirrup, a form which is particularly suitable for double bogie cars, which usually have the pilot-board comparatively near the front edge of the platform. This pattern ensures the satisfaction of the Board of Trade requirement regarding the distance between the feeler and front edge of the tray of the lifeguard. The device was inspected some time ago by Col. Yorke, who expressed the opinion that it was a decided improvement on the existing lifeguards.

EXPLOSION AT FERNIEGAIR COLLIERY, HAMILTON

AN inquiry was held on July 29th at Hamilton, Scotland, into the circumstances attending the death of two machine men and a miner consequent upon an explosion which took place in the Forniegair Colliery on June 27th. The proceedings were reported in full in the *Colliery Guardian*, from which the following notes are abstracted. It appears that the three men had been working with an electrical coal-cutting machine, to which a long, trailing cable was attached, and the work having proceeded so far that an extension of the cable was necessary, they proceeded to disconnect the cable and insert an additional length, with a plug and socket connection without first switching off. There happened to be gas and coal-dust in the workings, and apparently this was ignited by the sparking when the attempt to connect up the new cable-length was made.

The fireman of the pit in question stated that he had never heard of gas being in that pit before. The coal-cutter had been in use for five years, and, to his knowledge, no trouble had been experienced with it. He had not examined the pit on the morning of the explosion, but another man had done so instead and reported it free from gas. W. Gray, the electrician, said that he had tested the electrical fittings of the pit on June 21st, and had found everything satisfactory; they were also in good condition after the explosion. The amount of electricity delivered down the mine did not exceed 200 b.h.p., and so, according to Rule 11 of the Home Office rules for mines, it was not necessary for a competent man to be in attendance below ground. Mr. Robert Nelson, H.M. Electrical Inspector of Mines, said that a spark would undoubtedly be caused at the instant of connecting the two ends of the cables. The plug connection was, in his opinion, not suitable, and the conditions at the colliery on the day of the explosion simply invited an explosion immediately gas made its appearance. For a pit in which safety lamps were used, the design of the gate-end box was bad, as no precaution was taken to have it totally enclosed and gas-tight. There was evidence of considerable sparking, and it was his opinion that sparking occurred on the date of the explosion. It was, of course, an improper thing to try to insert a new length of cable without switching off the current first.

Mr. George L. Kerr, mining engineer, Glasgow, called as a witness for the colliery owners, was of opinion that if sparking had taken place at a break in the cable 30 ft. below the coal-cutting machine, while two of the men were working above that, the gas would either have shown on the lamps or put them out, but this had not happened. There was no doubt that a naked light was the cause of the accident, but he would not go the length of admitting this had been an electric spark. It was certainly not a proper thing to manipulate the cable in the presence of gas.

The jury found that the three men met their death in consequence of an accidental explosion of firedamp and coal-dust, concluding their verdict as follows:—"In the opinion of the jury, a spark from the electric plant ignited the gas and caused the explosion. The jury are of opinion that, whether or not the workmen were to blame for manipulating a 'live' cable in the presence of gas, the employers were in fault in respect (1) that the examination by the acting fireman on the morning of the explosion had been perfunctory and insufficient to discover gas; (2) that the electric plant was not suitable for a fiery mine; and (3) that there was an absence of due inspection from time to time of the electric apparatus installed in the pit."

Strike of Electricity Works' Employees in Stockholm.—On Thursday evening last the workmen at the Stockholm generating station joined the general strike, and on the same day the traffic and workshop staffs of the Gothenburg tramways ceased work. The men employed in the gas works have also gone on strike.

RADIO-TELEGRAPHIC APPARATUS FOR SHORT DISTANCES

AN article in the July issue of the "Post Office Electrical Engineers' Journal," by Mr. A. C. Booth, describes some experiments recently carried out between the Post Office radio-telegraphic stations at Skegness and Hunstanton, in conjunction with Mr. J. E. Taylor, with a simple form of sending apparatus suitable for short distances.

It was arranged that the height of the aerial wire should not exceed 80 ft. Two $\frac{3}{18}$ stranded copper wires were joined together at the base, but separated by about four feet with wooden spreaders till they reached the required height of 80 ft.; they were then extended outward and downward in opposite directions for 70 ft. The insulators were 6-in. ebonite links. The earth-plate was the ordinary earth-plate of the station, being a fan of 6-in copper strips buried about two feet below the surface of the earth. An ordinary high-speed trembler ignition coil, as used on motor cars, was employed, and current was

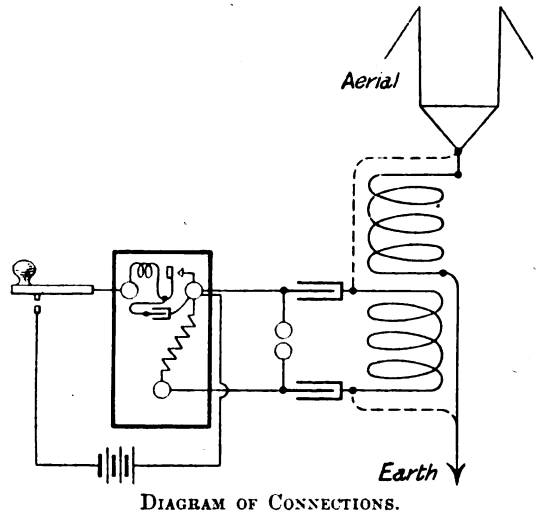

DIAGRAM OF CONNECTIONS.

supplied from three small secondary cells. The high-tension side was joined to a spark gap consisting of two brass balls, one inch in diameter, separated $\frac{1}{32}$ of an inch. Each side of the spark gap was connected to a Leyden jar of 0·003 microfarads capacity, and the other coatings of the two jars were connected together through an inductance of four turns of stranded copper wire wound on a wooden box, approximately 12 inches square, giving a wave length of about 800 ft. Four turns of similar wire wound on another box of the same size were placed in the aerial circuit. The boxes were arranged to be movable so that the degree of coupling could be varied.

In subsequent experiments the separate aerial inductance was omitted, and glass plate condensers were substituted for the Leyden jars. Good, reliable signals of almost a musical note were received across the sixteen miles separating the two stations by means of a De Forest electrolytic receiver and by a Marconi magnetic detector.

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL

NOTICES have been given of a number of amendments on the third reading in the House of Commons of the Electric Lighting Acts (Amendment) Bill. Sir Frederick Banbury will move the re-insertion in Clause 16 of what has come to be known as the Avebury amendment, viz., that a local authority may only undertake electric wiring, &c., through a contractor. Standing Committee C., it will be remembered, cut this addition of the House of Lords out of the Bill. The Standing Committee also struck out the word "meters" from the list of things which local authorities might provide, let for hire, fix, repair, and remove, but Lord Ronaldshay will move the re-insertion of this word.

Sir Frederick Banbury has also given notice to move the addition of the following at the end of Clause 16 :—

"(*d*) Nothing in this section shall, in cases where, within three months after the undertakers have obtained any loan necessary for the purpose of the undertaking, there is or are no firm or firms carrying on the business of electrical contractors within the area of supply, prevent the undertakers themselves from exercising the powers given by this section without the employment of a contractor.

(*e*) If the undertakers fail to comply with the provisoes (*a*), (*b*), and (*c*) of this section, they shall, under the Summary Jurisdiction Acts, be liable to a fine not exceeding ten pounds, and to a further fine not exceeding five pounds for each day on which the offence is continued after conviction therefor."

The provisoes referred to relate to the adjustment of charges for wiring, &c., in order to prevent any loss on the transaction, the rendering of separate accounts for this work, and the publication of a separate account in the annual accounts of the electricity undertaking. Similar sub-sections were deleted from the Bill by the Standing Committee.

Mr. Scott Dickson and Mr. Younger have both given notice that they will move the insertion of the following clauses, which prohibit unauthorised undertakers from competing with statutory undertakers :—

"Where in any area a local authority, company, or person is authorised to supply electricity under Act of Parliament or under licence or Provisional Order granted under the Electric Lighting Acts, it shall not, after the passing of this Act, be lawful for any other local authority, company, or person to supply, distribute, or transmit electricity within the same area unless such supply, distribution, or transmission is authorised by Act of Parliament or by licence or Provisional Order granted in terms of the Electric Lighting Acts. Provided that this section shall not prevent any company or person from affording a supply of electrical energy to any other company or person where the business of the company or person affording the supply is not primarily that of the generation or distribution of electrical energy."

"Nothing in this Act contained shall supersede, prejudice, or affect the provisions of any local Act or any Order confirmed by Act of Parliament applicable to any undertakers."

Notice of a few other amendments have been handed in which give railway companies and canal companies all the rights of a county council in respect to the repair of main roads carried over their property.

TRUNK TELEPHONE CIRCUITS BETWEEN FRANCE AND SPAIN

WE announced a few weeks ago (ELECTRICAL ENGINEERING, July 1st, page 597), that arrangements were in progress for extensive new trunk telephone lines for direct communication between the principal important towns in France and Spain. Through the courtesy of the Engineer-in-Chief to the Post Office, we are enabled to publish a few further particulars which have been received from the chiefs of the French telegraph and telephone services. It appears that although the scheme has been gone into in considerable detail, the actual convention between the French and Spanish Governments has not yet been signed. Negotiations between the two administrations are, however, in an advanced state, but, of course, all the details of the scheme are not yet definitely decided upon. So far, however, it has been agreed that the following main lines be put up with conductors of copper wire of the dimensions given below :—

Bordeaux—Madrid	5	millimetres.
Cette—Barcelona	5	,,
Bayonne—St. Sebastien	3	,,
Perpignan—Gerond	3	,,

Further details of the proposed system are not at present available.

Accident to a Turbine at Niagara.—According to the *Electrical World*, one of the new 10,000-h.p. turbines of the Niagara Falls Hydraulic Power & Manufacturing Co. broke down on Sunday afternoon, and two employees were injured. The casing burst, and a piece of metal was hurled across the station, which was partly flooded with the outrush of water. At the time the wheel was moving under about 75-lb. pressure, but has successfully withstood much higher pressure. A defect in the casting is suspected as being responsible for the break.

Electric Traction on Main Lines in Austria.—Detail designs for the electrification of a number of sections of the Austrian State railway system, which are suitable from both technical and economical standpoints for conversion to electric traction, are in course of preparation. These sections are as follows :—Innsbruck—Lindau (Arlberg railway), Feldkirch-Buchs, and Bregenz—St. Margarethen (together 233 km.), St. Veit—Assling—Trieste (Karawanken and Wocheiner railway, 204 km.), Trieste—Herpelje—Kozina (23 km.), Trieste—S. Sabba (5 km.), Trieste—Buje (59 km.), Trieste—Barcola (5 km.), Görz—Haidenschacht (Wippachtal railway, 27 km.), Bozen—Meran and Meran—Mals (Vintschgau railway, 91 km.), Mals—Landeck (the proposed Reschen railway, 98 km.), Schwarzach—Spittal, Villach—Rosenbach (Tauern railway, 137 km.), and Steinach—Irding—Attnang—Puchheim (Salzkammergut railway, 107 km.). These sections make together 980 km., or some 612 miles, which is about a quarter of the total length of lines lying in districts with available water-power.

RAILLESS ELECTRIC TRACTION

THE subject of railless electric traction is receiving some attention in Madras, where tramway extensions are being considered, and considerable objection has been advanced as to the presence of rails along certain routes, notably that over Government House Bridge and up Mount Road, where, however, overhead construction is not so much objected to. The *Madras Times* has an article dealing with the question which is strongly in favour of the railless system being used for the extensions. It is pointed out that, apart from the absence of rails, there are other great advantages. It is claimed that the cost of construction is only from one-fourth to one-third of the average cost of an electric tramway, thus necessitating less capital expenditure. In rapidity of construction it is also ahead, as the work is confined to building the cars and fixing the overhead equipment. It also has the advantage of being confined to one track, but has play over a wide stretch of road. It also has a field into which the tramway cannot enter. As a means of transporting goods from docks or warehouses to shops it is eminently useful. Not being confined to rails the car can draw up at the side of the road and discharge its contents without in any way dislocating the rest of the traffic. The trolley arm is constructed to give a lateral deviation of 10 ft. on either side of the wires, so that if, as in most cases they are, the overhead wires are placed in the centre of the road, the car has command of a width of road amounting to 20 ft., sufficient to cross or overhaul any other vehicle. Advantages are also claimed in the matter of reduction of noise.

The system has been reported on favourably by more than one committee in this country, who has seen examples of its working on the Continent, especially for extension routes in sparsely populated districts, where the capital expenditure for track is not justified, and the Railless Electric Traction Co. have already complete a large British-made vehicle, which, together with a small car brought from Germany, is about to undergo experimental trials at Hendon, by arrangement with the Metropolitan Electric Tramways, Ltd.

SIMPLEX CONDUITS, LTD., AND THE ELECTRICAL CONTRACTORS' ASSOCIATION

A SOMEWHAT new departure in business methods is contained in an agreement which has recently been entered into between Messrs. Simplex Conduits, Ltd., and the Electrical Contractors' Association, with the object of defining clearly the relations between manufacturer or wholesale dealer, contractor and consumer. The main feature of the arrangement relates to cases where goods are bought direct by a consumer without the intervention of a contractor, and full list price is charged. The Simplex Co., if they can trace a contractor to whom the introduction is due, will pay him half the difference between the trade and list prices, but if they are unable to trace any connection of an electrical contractor with the transaction they undertake to pay a corresponding amount with the funds of the Electrical Contractors' Association, and this will also be done in case of a dispute between the contractor, both claiming the introduction. The Association, in consideration of this undertaking, guarantee publication of the agreement among their members, and further undertake "to urge their members to purchase their requirements from the company and to give the company's goods preference in case of equal value and equal prices." It must be understood that the Simplex Co. do not give any preferential terms to members of the Association, and it is expressly stated that nothing in the agreement shall prevent the Association entering into similar agreements with any manufacturing firm or company. The agreement does not apply to goods sold to the public at the Simplex Co.'s stand at the Imperial International Exhibition, where an arrangement is already in force whereby 5 per cent. on all such sales is paid to the Electrical Contractors' Association.

Collision on Metropolitan Railway.—On Thursday two trains on the Metropolitan Railway came into collision at Moorgate Street Station, resulting in superficial injuries from broken glass to five passengers. The collision is attributed to a failure of the automatic signalling arrangements, which have recently been installed

The Junior Institution of Engineers.—The summer meeting of this Institution in the Midlands opens on Saturday at Leamington. The visits of electrical engineering interest arranged for include the engineering department of Birmingham University; Messrs. Herbert's machine tool works, Coventry; Messrs. Elkington's electro-plating works; the Summer Lane electricity works of the Birmingham Corporation, and the electrical signalling apparatus of the Great Western Railway at Snow Hill Station.

ELECTRIC POWER IN MINES

THE following particulars of the electrical equipment of the Florence Colliery of the Florence Coal and Iron Co., Ltd., at Longton, and the collieries and works of the Stafford Coal and Iron Co., Ltd., near Stoke-on-Trent, abstracted from an article in *The Iron and Coal Trades Review*, are of interest. The Florence Colliery has two shafts sunk to depths of 846 and 890 yards respectively, the latter being the deepest coal-winding shaft in the United Kingdom. At present steam winding engines are employed for both shafts. Ventilation is effected by a high-pressure turbo-fan, recently put in by Messrs. C. A. Parsons & Co. Its capacity is 250,000 cubic feet of air per minute at 12 in. water gauge and 2,500 revolutions per minute. The power-house has lately been extended to meet the requirements of the electrical haulage, the electrical coal-cutting machines, &c., and the new plant comprises a 750-kw. direct-current turbo-generator, by Messrs. Parsons & Co., and a 200-kw. direct-current generating set by Messrs. W. H. Allen & Co., Ltd., of Bedford. Steam is provided for the power-house and the turbo-fan at a pressure of 160 lbs. A feature of the surface works is a central condensing plant capable of dealing with 78,000 lbs. of steam per hour. The steam is led by a main 30 in. in diameter into an oil separator. Thence it passes into two surface condensers with 4,200 sq. ft. of cooling surface each. There are no horses underground, the haulage being entirely electrical. A large number of electric coal-cutters are used, and a short time ago 93 per cent. of the output of the mine was being cut by these machines.

At the power-house of the Stafford Coal and Iron Co. who have blast furnaces (the ironstone being worked as well as the coal), chemical works, and a brickworks, besides two groups of pits (the Great Fenton Colliery), there are three exhaust turbines, one blowing the blast for the furnaces and two driving three-phase generators. The turbo blowing engine is by Messrs. Parsons, its capacity being 14,000 cubic feet of air per minute, and its maximum speed 3,250 revolutions per minute. The turbo-generators have a respective capacity of 300 and 500 kw., and give a voltage of 3,000. The first is by Messrs. Parsons, and the second by Messrs. Bruce Peebles & Co., Ltd. The current supplied is used mainly for haulage, pumping, and coal-cutting.

There are four blast furnaces, 65 ft. high, and for the purpose of supplying these a bunker of 600 tons capacity has recently been erected, the coal passing to them from the shaft by means of conveyors. The furnace gases on leaving the blast furnaces are taken to the by-products works, where pitch, creosote oils, and ammonium sulphate are obtained. The washed gas is used for heating the blast from the furnaces and raising steam.

In a Paper read recently before the Mining Institute of Scotland, and reported at length in *The Iron and Coal Trades Review*, Mr. J. Paul described the application of electric power to coal-mining as exemplified by the equipment of the collieries of the Lochgelly Iron and Coal Co., Ltd., Fife. On the coalfield of the company there are ten pits distributed over an area of 16 square miles, and raising an aggregate of 1,250,000 tons of coal per annum. Until the end of last year electricity supply for both power and lighting was provided through this area by numerous isolated continuous-current plants of low- and medium-pressure. Early in 1907, the increase in demand for electric power made it imperative for the company to consider the question of increasing the supply of electrical energy to several of the pits. Generation at a central power-house and overhead transmission to the distant pits by high-pressure three-phase current having been agreed to, it was decided to instal, to begin with, plant sufficient to deal with five of the pits and workshops, but to design the lay-out with a view to the ultimate inclusion of the whole field in the scheme. A schedule of the motors immediately to be provided for having been drawn up, and the incidence of load and the diversity factor taken into account, the load diagram was deduced. From this diagram it was seen that between the hours of 6 p.m. and 6 a.m. the estimated maximum load was 613 b.h.p., and during the remainder of the twenty-four hours 761 b.h.p., or about 450 to 550 kw. respectively. It was, therefore, decided to provide in the first instance two generating units of about 450 kw. capacity each, and arrange accommodation in the power-house, in addition, for a third similar unit and a 1,000-kw. exhaust or mixed-pressure turbo-generator; and also to so design and arrange the first portion of the equipment that no part would require modification if and when extensions became necessary.

Examination of the relative advantages of turbines and reciprocating engines for the size of units required, continues the author, resulted in favour of the last named, both as regards cost per kw. capacity and steam consumption per kw. output, the quotations and guaranteed steam consumption appearing to be in favour of the reciprocating engine for units of 1,000 kw. capacity downwards. At the beginning of 1909 the power-house, transmission line, and transformer sub-station were put to work, and the change over from the old direct-current drive to the new three-phase system commenced. Separate contracts were made for each part of the scheme, and, except

Digitized by Google

in the case of the transmission line, the several contractors provided a chargeman only, the company supplying all the other labour required. Recently, it may be mentioned, the company acquired the Dundonald Colliery, and this has now been included in the area of the new supply; an extension of about two miles to the transmission line having been made for this purpose.

Having thus explained the nature of the scheme, the author passed on to give a brief description of the completed works. He detailed the leading features of the four Babcock & Wilcox boilers, the feed-pumps by Messrs. Andrews & Cameron, Kirkintilloch, the steam pipes for both pressure and exhaust by Messrs. Stewarts & Lloyds, Coatbridge, the two Bruce-Peebles three-phase 50-period alternators, the evaporative condenser by Messrs. Ledward & Beckett, Ltd., the feed-water purifier—a Harris-Anderson plant—and the switchgear, supplied by the British Westinghouse Co. He also touched upon the motor-generator for lighting, supplied by Messrs. Mavor & Coulson, the high-tension distributing system as erected by Messrs. Johnson & Phillips, and other items of interest in the scheme. In conclusion, he stated that as to the outlay, it might be taken that the generating costs, based on the load diagram, plus the capital charges, namely, interest on capital and sinking fund to redeem the capital in twenty years, would enable the company, by the equipment described, to deliver electrical energy at any point in the coalfield for something less than 0·3d. per unit; and that with an increased load the cost per unit would be even cheaper, owing to the fact that much of the expenditure already incurred really belonged to these possible and probable extensions.

High-tension Transmission in Colorado.—According to the *Electrical World* (New York), a portion of the transmission system of the Central Colorado Power Co. was temporarily run at the full pressure for which it was designed, namely, 100,000 volts, to test the line. The Denver sub-station, which is connected with the steam stations of the Denver Gas & Electric Co. in Denver, was supplied at this pressure for a short time from the water-power plant in Shoshone, nearly 200 miles away.

Telegraph Traffic and Movements of Cable Ships.—It was only on the 10th ult. that the cable of the West India and Panama Telegraph Co. was restored to working order, and on the 4th inst. the cable again broke down. The cable to Demerara is continually giving trouble, but the wireless installation at Trinidad is apparently completed, for trial messages have passed between the two Colonies, and this will probably afford relief.—The line between Saigon and Bangkok is damaged, and messages are sent *via* Obone, which causes some delay.—The line between Rome and Constantinople broke down on the 4th inst., and was repaired on the same day.—Another interruption occurred on the 6th inst., the cable between Gibraltar and Tangier failing.—On the 7th inst., the cables between Ceuta and Tangier, and between Melilla and Chafarinas, were on the non-operating list. The Morocco troubles are probably directly accountable for this.—The line between Bagdad and Bassorah is also down again.—The cable steamer *Relay*, of the Mexican Telegraph Company, has been engaged on the repair of the New York-Guantanamo cable, which was interrupted off Cape Hatteras in about two miles of water. Some difficulty was experienced in grappling the cable, and the Telegraph Construction & Maintenance Company's steamer *Cambria* was chartered to assist in the repair. She left for the scene of operations on July 18th.—The new cable-repairing steamer of the Western Union Telegraph Company will have a length of 150 ft. and a beam of 32 ft. Her captain is Captain Olmstead, and Mr. Alexander Klein is in charge of the electrical work.

The Electrical Industry in the Argentine.—The American Consul-General at Buenos Aires, reporting upon the opportunities in the Argentine Republic for the employment of American electrical engineers, states that in the installation of tramways, city lighting plants, telephones, &c., the standard of the practical electrical engineer in this country is a high one. Installations of the higher order of engineering, such as first-class elevators, motors in modern offices and hotels, &c., are in their infancy. There certainly is an opening for first-class electrical engineers, and they will be successful if they conform with the customs of the country to a certain extent, but they must remember that electrical and other engineers in Argentina are paid fully 20 per cent. less than the usual pay of engineers in New York. At the present time there are a number of important and large modern buildings, and others not so costly, to be constructed in Buenos Aires. As an example, the Plaza Hotel, when completed, will cost over £500,000. The Government contemplates large port improvements, and the railroads are about to construct large stations. The latter will be in English hands, however, as they are controlled by English capital, and therefore English mechanics and engineers will be preferred. The principal difficulty to be encountered by American engineers in getting a foothold lies in the fact that the most important works are almost wholly financed by English, German, or French capital, and naturally the important posts fall to the engineers of the countries furnishing the capital.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

METAL FILAMENT LAMPS.—A leaflet from Mr. G. Braulik, contains particulars of the "Eclipse" metal filament lamps, which are listed in a number of sizes, ranging from 25-volt, 5-c.p. lamps, to 250-volt, 250-c.p. An important feature of these lamps is their small bulb. Even the 50-c.p. lamp has a bulb not exceeding five inches in length.

TECHNICAL BOOKS.—We have received from Mr. H. K. Lewis's Medical and Scientific Circulating Library a catalogue of new books and editions recently added to the library, which includes a number of works dealing with electrical science and engineering.

ELECTRIC HOOTERS FOR AUTOMOBILES.—We have received from Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster, S.W.), a copy of a reprint of an illustrated article describing the construction and operation of the firm's electric hooters, recently published in *The Automotor Journal*. These instruments are made to work at 4 to 8 volts for petrol cars, or with considerably higher pressures for electric cars, and contain a metal diaphragm which is set in vibration by means of an electromagnet and trembler device. A condenser is used to suppress sparking, and the current consumption is very small.

ELECTRO-MEDICAL APPARATUS.—A new leaflet issued by Messrs. Siemens Brothers & Co., Ltd., contains an interesting summary of the present applications of electricity to medicine and surgery. It is divided into two sections, dealing with apparatus for use on continuous-current and alternating-current circuits respectively, the necessary devices for converting from D.C. to A.C., or *vice versa*, being briefly described in each case. Portable X-ray outfits, and the latest equipments for instantaneous radiography, are referred to and illustrated. High-frequency apparatus, and the accessories required for what is known as the fulguration treatment for cancer, are also mentioned. For large X-ray outfits, working from D.C. supply circuits, the use of a small rotary-converter and transformer, together with a rotary device for commuting the high-tension current, is recommended in place of the more usual coil and interrupter. Two further new supplements to the firm's electro-medical catalogue of June, 1908, have also been issued. These relate to a clinical temperature recording outfit for obtaining a record of the temperature variation of a patent, and to radio-active substances supplied by the Banque du Radium, Paris, respectively. The recording thermometer comprises a platinum resistance spiral fused into a quartz tube and connected to a 4-volt accumulator, and a recording milli-voltmeter calibrated to read in degrees Fahrenheit. Two patterns of recorders are listed, with suspended and pivoted coils respectively, the former being the most accurate and sensitive, while the latter is more suitable for general work.

Electric Lighting and Tramways in Jerusalem and Damascus.—An American Consular report states that a concession for the electric lighting of Jerusalem, and the construction of an electric tramway between Jerusalem and Jaffa, has been applied for. The daily receipts of the electric tramway in Damascus average about £35. A considerable extension of the system is under preparation. Electric lighting has been introduced into 450 buildings in Damascus, and the streets are lighted with over 1,000 lamps.

The Telegraphic Transmission of Drawings.—A description of a system of picture-telegraphy invented by M. Laurent Semat of the Egyptian Railways, appears in the current issue of the *Elektrotechnischer Anzeiger*. The line drawing to be transmitted is drawn or printed with ink on a sheet of metal foil which is wrapped round the transmitting drum, and a needle resting on the surface breaks and makes circuit as the ink lines pass under it. On the drum of the receiving instrument is a sheet of carbon paper, over which is wrapped a sheet of ordinary paper, the breaks in the circuit apparently being made to cause a depression of a needle resting on the receiving drum. To obtain synchronism, the two drums are of unequal diameter, the circumference of the transmitting drum being $\frac{1}{4}$ of the receiving drum. The relative speeds of the drums are such that when the transmitting drum has made a complete revolution, the receiving drum has made $\frac{1}{4}$ of a revolution. The single vertical line of the picture has, however, been recorded completely and to the same scale, owing to the difference in the diameters of the drums. At this point the rotation of the transmitting drum is stopped by a detent held in place by an electromagnet. Directly the receiving drum has completed its revolution, it causes the line circuit to be broken, and, the electromagnet being de-energised, the detent falls away, and both drums start a new revolution simultaneously.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 5th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

8,426/08. **Fixation of Atmospheric Nitrogen.** Allgemeine Elektricitäts-Ges. The treated air, containing some 2 to 4 per cent. of NO, after being passed through the oxidation chambers where the NO is converted to NO_2, is passed through apparatus containing weak basic oxides of zinc, copper, or lead. When all the oxides of nitrogen are absorbed, the salts are slowly heated in iron retorts to a temperature of 500° C. The oxides are given off in the form of pure peroxide of nitrogen which is then converted in water towers to 40 per cent. commercial acid, or condensed as peroxide of nitrogen. If the heating of the salts is performed in a vacuum, a much lower temperature is required. One claim.

14,852-3/08. **Metal Filaments.** C. Trenzen and F. R. Pope. The first specification is for a process of manufacturing filaments of titanium, by mixing the mixture of titanium and titanium nitride obtained by treating titanic acid with ammonia, with a binding agent containing carbon. On heating filaments squirted from this mixture, the carbon combines with the nitride to form titanium cyanide which evaporates away, leaving a pure titanium filament. In the second specification, a process in which a non-carbonaceous aqueous solution of a tungsten ammonium salt is squirted into a water absorbing liquid as alcohol, is described. Stopping up of the dies is said to be obviated as the filament is coagulated after the mass has been passed through. One claim each.

15,047/08, 13,762/09, and 13,763/09. **Series Transformer Switch.** J. S. Peck. These patents relate to automatic switching gear for cutting a large transformer in or out of circuit in accordance with the load on the distributing sub-station, similar to that described in Electrical Engineering, Manchester Exhibition Supplement, October 22nd, 1908, page 36.

16,144/08. **Driving of Spinning Frames.** J. & T. M. Greeves, Ltd., and R. V. Eves. A small pinion fitted on the shaft of the induction motor engages with an internally toothed wheel on the frame, and the base-plate is so arranged that the motor can be moved in two directions at right-angles to each other for the purpose of changing the pinion. The bearing for the driving shaft is mounted on the base-plate of the motor to eliminate all spring between the two shafts. Four claims, three figures.

20,758/08. **Fuses.** Bertram and E. Thomas. In order to keep the main contacts and bodies of tubular and other fuses cool, metal vanes or strips are inserted between the fuse itself and the contacts, so that the heat generated in the fuse shall be quickly radiated and not conducted to the contacts. Two claims, two figures.

11,904/09. **Commutator Construction.** Siemens-Schuckertwerke-Ges. According to a previous patent, the segments are supported on the shaft by means of intermediate seating rings and inner rings composed of segments. When the fixing nut is screwed up, the inner rings contract, and the intermediate rings expand, and the segments are held between the latter and outer rings shrunk over the whole. The intermediate rings have a tendency to set themselves in an oblique position, resulting in the bending of the shaft, and to prevent this, the present invention provides for the shaping of the contact surfaces (at one end) to the surface of a sphere, the centre of which is in the axis of the shaft. Two claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Control mechanism for projectors, &c.] 16,722/08; Kent, Lacell, and Silica Syndicate, Ltd. [Mercury vapour lamps] 21,834/08; Pauling [Working arcs in series] 6,429/09.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Machine for forming porcelain insulators] 12,974/08.

Dynamos, Motors, and Transformers: British Thomson-Houston Co. (*Allgemeine Elektricitäts-Ges.*) [Motor-generator for supplying arc lamps] 15,130/08; Bigge and Butt [Induction coils and transformers] 19,886/08; Buchwald [Speed control of machines] 4,765/09; Delon [High-tension A.-C. to D.-C. converter] 13,450/09.

Electric Ignition: Mulholland [Ignition devices for internal combustion engines] 24,403/08.

Electrometallurgy and Electrochemistry: Kilburn (*Oesterle*) [Electric furnaces for treating ores] 15,645/08; Johnson (*Badische Anilin und Soda Fabrik*) [Manufacture of nitrates] 20,406/08; Weatherill [Dry cell with renewable zinc] 23,622/08; Aktiebolaget Elektrometall [Electric furnaces for production of iron and steel] 6,088/09.

Heating and Cooking: Read [Electrically-heated hand irons] 15,674/08.

Incandescent Lamps: Girard [Mounting lamps] 425/09; Bohm, 3,897/09.

Instruments and Meters: Wilson [Prepayment meter], 109/09; Fèry [Pendulum meters], 687/09.

Storage Batteries: Haddan (*Nya Ackumulator Aktiebolaget Jungner*) [Electrodes], 21,004/08; Van Raden & Co., and Metz, 25,478/08.

Switchgear, Fuses, and Fittings: Hill [Lamp-shade holders] 17,706/08; Day [Sign switch] 17,794/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Circuit-breakers] 19,589/08; Nelson, and Drake & Gorham, Ltd. [Lamp-shade carrier] 19,705/08; Siemens Bros. Dynamo Works, Ltd. (*Siemens Schuckertwerke-Ges.*) [Overload circuit-breakers] 20,268/08; Timar and Ziegler [Time-relay] 26,967/08, and 8,570/09; Felten & Guilleaume-Lahmeyerwerke A.-G. [A.C. indicators] 8,191/09.

Telephony and Telegraphy: Raymond-Barker and Orling [Relays and relay systems] 15,853/08; Kingsbury (*Western Electric Co.*) [Transmitting, retransmitting, and reinforcing telephone currents] 17,048/08; Aitken [Telephone instruments] 21,405/08; Winterbottom [Supports for telephones] 25,122/08; Siemens Bros. & Co. (*Siemens & Halske A.-G.*) [Telephone exchanges] 4,594/09; Pictet [Telegraphic receivers] 10,450/09; Hall [Safety devices for telephone and telegraph lines] 12,869/09.

Traction: Finnigan [Signalling] 15,494/08; Borland and Horsley [Life-saver for tramcars] 15,840/08; Curwen (*J. G. Brill Co.*) [Current collectors] 16,305/08; Dobson and Smith [Life-guards for tramcars] 18,564/08; Stevens [Converting petrol 'bus chassis to electric driving] 20,210/08; Venning [Tramway frogs and crossings] 7,795/09.

Miscellaneous: Wilderspin and Hough [Coil-winding machine] 15,053/08; Leslie Walker Fire Alarm Co., and Walker [Fire alarms] 15,572/08; Kilburn (*Oesterle*) [Magnetic separators] 15,646/08; Derham [Motor-operated drills] 1,193/09; John Musgrave & Sons, Ltd., and Pope [Exhaust-steam heat accumulator] 11,378/09.

The following Specifications are open to Inspection at the Patent Office for Acceptance, but are not yet published for sale.

Arc Lamps: Timar and Von Dredger [Prevention of flickering] 1,541/09.

Distributing Systems, &c.: Kallman [Load equalising apparatus] 7,754/09; Greiner [Detection of faulty line insulators] 14,952/09.

Dynamos, &c.: Siemens & Halske A.-G. [Insulation of former-wound coils] 16,985/09.

Electric Ignition: Delage and Wood [Amplifying device] 16,732/09.

Incandescent Lamps: Soc. Française d'Incandescence par le Gaz (Système Auer) [Metal filaments] 15,192/09, and 15,193/09.

Instruments, &c.: O'Keenan [Shunt for wattmeter] 15,298/09.

Traction: Bujon and Compagnie de Signaux Electriques pour Chemins de Fer [Signalling] 15,863/09; Chéradame [Wheel for electric vehicles] 16,340/09.

Miscellaneous: Kjellman [Fire-arms] 23,187/08; Zhaniel [Stage lightning effects by high-frequency currents] 16,309/09.

Expiring and Expired Patents

The following Patents expire during the current week after a life of fourteen years:—

15,215 of August 13th, 1895. **Telegraphic Printing Apparatus.** C. L. Buckingham. The signals, which are preferably sent automatically, are received by a form of electromagnetic typewriter, which records the messages in page form.

15,445 of August 16th, 1895. **Telegraphic Printing Receiver.** W. S. Steljes. This receiver has a type-wheel driven by clockwork, and controlled by an electromagnet excited with alternating current.

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, &c.: R. Rougé [Armature winding] 9,057/02; G. M. Wright [Machine for taping coils] 9,236/02.

Instruments and Meters: J. Ferguson and Kelvin & James White [Multicellular electrostatic voltmeter] 8,791/03.

Switchgear, &c.: W. G. Haywood and S. G. Brounger [Motor-starting switch] 8,922/04.

Telephony and Telegraphy: S. G. Brown [Submarine cables] 9,040/02, [Galvanometer for indicating uncompensated self-inductance or capacity in cables] 9,040A/02, and [Telephone relay and duplex working] 9,044/02.

Miscellaneous: F. W. Golby (*A. König*) [Electrical device for feeding sheets to printing and folding machines] 7,277/00; G. B. Francis [Gear for rotating electric lamps] 8,923/03; M. Wehrlin [Electrically controlled type-casting and composing machines] 9,325/03; G. A. Peters [Electric targets] 9,008/04.

Digitized by Google

LOCAL NOTES

AUCHTERDERRAN (Kirkcaldy): *Electric Lighting.*—The Kirkcaldy District Committee have consented to a proposed application by Mr. G. Balfour for an electric lighting provisional order for this district.

AUSTRALIA: *Hampden (V.): Electric Lighting.*—The Council's loan of £7,000 in connection with an electric lighting scheme, says the *Australian Mining Standard*, was over-subscribed, the £100 debentures at 4 per cent. being eagerly taken up at par; in fact, in one case £101 was offered.

BIRKDALE: *Street Lighting.*—Electric lighting is gradually supplanting gas in the streets of Birkdale. Along the tramway route gas lamps have been entirely superseded, and altogether about three miles of street are electrically lighted, metal filament lamps being adopted.

BRADFORD: *Electricity Accounts.*—The accounts of the electricity department for year to March 31st show a net surplus of £2,146, against £1,135 in the previous year. Against this, however, has to be set a sum of £1,491 for adjustment of liabilities on March 31st, 1908, and a sum of £1,200 rebate to the Tramways Committee, in consequence of the Electricity Committee having failed to provide sub-stations for the transformation of the high-pressure current. The revenue from lighting supply for the year shows a decrease of £217, but that from power supply has increased by £4,064.

BUENOS AYRES: *Tramway Amalgamation.*—The City Council have unanimously approved the amalgamation of the Grand National, Capital and Metropolitan Tramways with those of the Anglo-Argentine Company.

BURNLEY: *Electricity Accounts.*—The accounts of the Electricity Department for the year to March 31st states that the revenue, viz., £21,685, is less by £704 than that of the previous year. The expenditure, on the other hand, £11,456, increased by £1,234. After meeting interest and sinking fund charges, however, there is a net profit of £4,169, of which £3,000 has been transferred to relief of rates, and the remainder placed to depreciation account. Reserve and depreciation account now stands at £17,665, which represents 17½ per cent. on the total capital expenditure. The total number of units sold was 3,148,875, compared with 3,434,979 in the previous year, but this latter included a large temporary supply. Leaving this out of account, there is actually an increase of 1·28 per cent. in the total units sold. Works costs have increased from 1·27d. to 1·33d. per unit.

CANADA: *Electric Traction.*—An American Consular report states that a new electric railway is to be commenced from Morrisburg to Ottawa, a company having been incorporated with a capital of £200,000. The power plants will be located at Morrisburg and Billings Bridge, Ottawa. Another line contemplated, called the Belt Line Electric Railway, covers practically the same route, but the Metcalfe Corporation in Carleton County propose to give the right of way to the company that begins work first.

HALIFAX: *Charge for Tramway Current.*—A proposal that the charge for energy to the Tramways Committee should be reduced to 1 1/5 d. per unit was withdrawn at the last meeting of the Corporation. If this charge were made, it was stated that the electricity department would lose £4,000 per annum. At present there is an adverse balance of £11,705 upon the working of the tramways, and it was decided to leave over the question of the charge for energy until this deficit is wiped out.

HASTINGS: *Home Office Regulations.*—The Borough Electrical Engineer has called the attention of the Electricity Committee to the fact that the new Home Office Regulations concerning the use of electricity in factories and workshops will involve alterations at certain sub-stations. The committee have come to the conclusion that the most effective and economical way of complying with the regulations would be to take out the existing transformers at the sub-stations at the works, the east end of Robertson Street, at the Hastings and St. Leonards and East Sussex Hospital, and at Shepherd Street, and to substitute at each sub-station two transformers of improved make and of greater capacity, which would increase the total capacity by over 100 per cent., would enable one at each sub-station to be used as a spare, and would, in addition, give more space in each station, and so enable the attendants to manipulate switches, fuses, &c., and to perform their duties generally with less danger than hitherto. The estimated cost of the alterations is £320, in addition to the cost of transformers. (See "Tenders Received" column.)

HORSHAM: *Electricity Accounts.*—After meeting capital charges, the accounts of the Council's electricity undertaking for the past year show a profit of £10. This is the first occasion since the inception of the undertaking that a profit has been made.

HYTHE: *Cost of Opposing Tramway Bill.*—The cost to the Council of opposing the Folkestone, Sandgate and Hythe Tramway Bill was £704, and it has been decided to levy a rate of 5d. in the £ to meet this.

INCE-IN-MAKERFIELD: *Transfer of Tramway Powers.*—The Council are transferring to the Wigan Corporation the tramway known as the Higher Ince Tramway, which is slightly over one mile in length. The lease is for twenty-one years.

IPSWICH: *Electric Lighting Accounts.*—The accounts of the electricity undertaking for the year to March 31st show a deficit of £351, compared with a loss in the previous year of £1,789. The loss this year, moreover, includes two special items amounting to £345. The total number of units sold was 1,399,990, compared with 1,261,614 in the previous year, the output for lighting having increased by 16·32 per cent, power by 28·61 per cent., and traction by 2·78 per cent. During the year negotiations were concluded with the Admiralty for supplying electrical energy for the new wireless telegraph station. A special feeder is to be laid for this purpose, but the cost will be borne by the Admiralty. The use of electricity for street lighting has received attention during the year, some 16 arc lamps having been erected. The free-wiring system introduced in March last year has resulted in 68 consumers being connected. The total revenue was £15,391, and the expenditure, apart from the special expenditure referred to, £15,397.

Tramway Accounts.—The tramway accounts for the year to March 31st show a deficit of £2,294, total revenue amounting to £20,169, and the expenditure to £22,463. The loss is attributed to bad trade and the necessity for meeting a number of special charges. The number of passengers carried was 4,811,411 against 4,979,253 in the previous year, the total revenue per car mile being 7·321d. and 7·624d. respectively.

LEEDS: *The Trackless Trolley System.*—At a recent meeting of the Corporation, the question of the precise powers of the Corporation to adopt the trackless trolley system, as recommended by a sub-committee a short time ago, was discussed. The Leeds Town Clerk holds the view that special Parliamentary powers must be applied for, and, in view of this, an interview was held with the Board of Trade, whose decision will be given later

LEITH: *Tramway Extension.*—The final portion of the extension to the Leith Corporation tramways between Leith and Newhaven, *via* Granton, was opened last week. The line inspected by Colonel von Donop of the Board of Trade has a length of three-quarters of a mile, the whole extension being four miles in length. The total cost has been £45,000, or nearly £2,000 below the estimate.

LONDON: *London County Council: Tramways.*—A new section of the Council's tramway system was opened last week. This is between Streatham and Norbury, a distance of 1½ miles. This extension brings the L.C.C. system into touch with that of the Croydon Corporation, and makes possible a ride by tramcar from Purley, in Surrey, to Barnet, in Hertfordshire, a distance of 22 miles. The latter place is served by the cars of the Metropolitan Electric Tramways, Ltd., which run from the terminus of the L.C.C. system at Highgate Archway.

St. Pancras: Electricity Accounts.—The gross income of the electricity undertaking for the year ended March 31st was £75.358, a decrease of £2,243 as compared with the previous year, and an increase of £1,187 in comparison with two years ago. The net profit was £6,925, as compared with £9,454 in 1908, and £6.495 in 1907.

MUSSELBURGH: *Tramway Extension.*—An extension of the Musselburgh & District Electric Light & Traction Co.'s tramway system, embracing Prestonpans, Cockenzie, and Port Seton, was opened last week after a Board of Trade inspection by Colonel von Donop.

OULTON BROAD (Suffolk): *Electric Lighting.*—The Council has decided to offer its electric lighting provisional order for transfer.

RUSSIA: *Electric Traction.*—The British Consul at Odessa states that in spite of the Government approval to their scheme for electrification of Odessa tramways, the Tramway Company have not yet been able to begin work owing to fresh preliminary difficulties. At Nicolaieff, although the Town Council has decided in principle to grant a concession for the electrification of the existing horse tramways, nothing definite has yet been settled.

Electric Supply.—The tender of the Société Anonyme des Tramways d'Odessa has been accepted for the construction of an electric supply station.

Telegraphs and Telephones.—The Government has assigned a sum of money for the improvement of the existing telegraph and telephone communication between this town and Odessa. The work should be undertaken this year.

SOUTHAMPTON: *"Free" Wiring.*—With reference to the note on p. 705 of our last issue relative to the acquisition of "free" wiring powers by the Corporation, it is interesting to note, in view of the agitation of the Electrical Contractors' Association in this connection, that Mr. H. F Street, the Borough Electrical Engineer, is anxious that all wiring should be carried out by wiring contractors and not direct by the Corporation. Mr. Street's opinion is that wiring contractors have better facilities for doing the work than the Corporation, as the class of men employed is quite different to those employed by the Corporation.

Digitized by Google

SOUTHGATE: *Electric Lighting.*—Before proceeding further with the question of transferring their electric lighting provisional order to the North Metropolitan Electric Power Distribution Co., Ltd., the Council have decided to submit the proposed agreement to Mr W. C. C. Hawtayne for his advice on the suggested terms of purchase.

TORONTO: *Electricity Supply.*—It is reported that the city authorities will not make any offer to take over the undertaking of the Toronto Electric Light Co. With regard to the new electric power undertaking which the Ontario Government have in hand, it is stated that 80 per cent. of the easements for the erection of the overhead line towers have been secured, and that eight miles of line have been erected. The towers are being delivered at the rate of 70 per week.

TUNBRIDGE WELLS: *Electricity Profits.*—From a report just issued, it appears that during the 14 years of its existence the municipal electricity undertaking has earned a gross profit of £59,327, the capital outlay being £80,519. The total number of consumers, viz., 960, represent one-sixth of the total number of ratepayers.

WALSALL: *Tramway Extension.*—A sub-committee has reported against the proposal to extend the tramways a distance of some fourteen miles to link up Brownhills, Chase Town, Chase Terrace, Five Ways, Cannock, Wyrley, and Bloxwich. The estimated cost of constructing such lines is put at £168,000, or £12,000 per mile, but the sub-committee does not think there is any prospect of the districts in question developing to an extent sufficient to render the undertaking unremunerative.

WALTON-LE-DALE: *Electric Lighting Order Revoked.*—The Board of Trade have revoked the electric lighting provisional order granted to the Council in 1904.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains &c.

AUSTRALIA.—The Geelong Harbour Trust have decided to erect an electric power house for lighting and power purposes.

EDINBURGH.—Tenders are invited for a motor alternator at the M'Donald Road electricity works. Particulars from the Electrical Engineer, and tenders to the Town Clerk by September 4th.

HOYLAKE.—A Local Government Board inquiry has been held into an application by the Council for sanction to borrow £2,000 for extension to their electrical undertaking.

KETTERING.—A Local Government Board inquiry will be held next week into an application by the Corporation for sanction to borrow £2,000 for the purposes of the electric lighting undertaking.

NEW ZEALAND.—H.M. Trade Commissioner for New Zealand (Mr. G. H. F. Rolleston) reports, says the *Board of Trade Journal*, that tenders are invited by the Golden Bay Cement Works, Ltd., for the supply and erection at Terakohe, Golden Bay, of a complete Portland cement plant of the most modern description, electrically driven, capable of a minimum production of 400 tons of cement a week. Contractors may tender for the whole plant, or separately for the power-house machinery and for the cement-making machinery. Other things being equal, preference will be given to British manufactured engines, boilers, dynamos, motors, pumps, condensers, &c. Foreign-made machinery is generally liable to a preferential duty of 10 per cent. in excess of British-made machinery. With each tender a deposit of £250 will be required, and a deposit of £1,000 must be made by the successful tenderer. Tenders will be received at the company's offices, Nathan's Buildings, Wellington, up to noon on November 1st. Copies of the specification may be seen by British firms interested on application at the Commercial Intelligence Branch of the Board of Trade.

RHYL.—The Council require a 125-kw. Diesel oil engine set and a 50-kw. steam generating set. Particulars from the Electrical Engineer and tenders by August 21st.

SWEDEN.—It is stated that a proposal is in hand to have the Railway Kiruna—Norwegian Frontier electrified. Surveys and experimental works are now being carried on. It is rumoured that tenders will shortly be invited for the execution of the necessary electrical lines, buildings, &c.

[illegible]DMORDEN.—A new generating set is to be installed at an estimated cost of £1,000.

Miscellaneous

EAST HAM.—Sanction has been received from the Local Government Board to borrow £1,836 for tramway purposes.

ECUADOR.—A draft contract has been arranged with the Government under which Mr. Julio H. Cardon is authorised to construct a 3 ft. 6 in. gauge electric railway from Babahoyo, capital of the province of Los Rios, to Balzapamba, in the province of Bolivar, with further powers to extend the line to Guaranda, capital of the province of Bolivar. The cost of construction is estimated at about £287,000, which amount will be guaranteed by the Government of Ecuador by an issue of bonds bearing interest at the rate of 6 per cent per annum, and 1 per cent. cumulative in respect of amortisation. The bonds will be repayable in 33 years. The *concessionaire* will have the right to work the railway on certain terms for a period of 50 years. All the material necessary for the construction, working, and maintenance of the line will be admitted free of customs duty.

LEYTON.—Tenders, to be considered early in September, are to be invited for 100 public lighting lanterns with clock switches, to complete the conversion of gas lamps in the district, also for wiring the extension of the public offices, now being erected.

LONDON: *Battersea.*—**Tenders** are invited for supplying and installing on consumers' premises direct-current motors, flame and enclosed arc lamps. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by August 21st.

SOUTH AFRICA.—The Imperial Trade Correspondent at Cape Town (Mr. E. J. Cattell), reports, says the *Board of Trade Journal*, that tenders will be received by the Chairman of the Tender Board, Control and Audit Office, Parliament Street, Cape Town, up to noon on September 29th, for the supply of dry cells, in such quantities as may from time to time be required, for the period July 1st, 1910, to June 30th, 1911. Forms of tender, copies of specification, and any other information may be obtained on application to the Controller of Stores, General Post Office, Cape Town, to whom six sample cells must be forwarded. The number of cells that will be required is estimated at 2,500. A few forms of tender, forwarded by Mr. Cattell, may be obtained by British makers on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

VENEZUELA.—The Director-General of National Telegraphs has authorised the municipal authorities of Libertad, district of Betijoque (State of Trujillo), to arrange for the installation of a telephone line between Libertad and Betijoque.

WARRINGTON.—Application is to be made to the Local Government Board for sanction to borrow £500 for transformers.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.E.—Alterations to Eastern Ambulance Station, Homerton. W. T. Hatch, engineer, Metropolitan Asylums Board, Victoria Embankment, E.C.

S.E.—Alterations to South-Eastern Ambulance Station, New Cross. W. T. Hatch, engineer, Metropolitan Asylums Board, Victoria Embankment, E.C.

New offices, Blackfriars Road (£5,460). Architect, A. C. Russell, Ilford.

PROVINCES.

ACCRINGTON.—St. James's Church. Architects, Grimshaw & Conliffe, Accrington.

BURNLEY.—Hippodrome. Architects, Watson, Ladlow & Rees, Burnley.

FROME.—Shops, Market Street. Architect, P. Rigg, 3 Cork Street, Frome.

GORLESTON.—Primitive Methodist Church (£623). Architect, A. S. Hewitt, Bank Chambers, Great Yarmouth.

GRANTHAM.—Girls' Secondary School (£6,[illegible]). Architect, H. H. Dunn, Silver Street, Lincoln.

HASLINGDEN.—Messrs. Peers, Copeland, and Carden, electrical advisers to the Board of Guardians, have been instructed to prepare a scheme for the electric wiring of the new infirmary and workhouse.

HOVE.—Conversion of premises, Church Road, into shops and flats. Builder, J. H. Hackman, 5 and 12 Western Street, Brighton.

LEEK.—Drill Hall (£3,000). Architect, W. Cowleshaw, Hanley.

School (£4,700). J. Hutchings, County Hall, Stafford.

LEIGH (LANCS.).—Mill. Architects, Bradshaw & Gass, Bolton.

SALFORD.—School, Robert Hill Street. Secretary, Education Committee, Town Hall, Salford.

WALSALL.—Drill Hall. Architects, Hickton & Farmer, Bridge Street, Walsall.

WATFORD.—Premises for Watford Co-operative Society, Ltd. (£1,222). Architect, C. P. Ayres, 6 The Parade, High Street, Watford.

WORKSOP.—Additions, Worksop College (£10,000). Architect, Sir Aston Webb, 18 Queen Anne's Gate, S.W.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The *Australian Mining Standard* states that contracts have been let by the Prahran & Malvern Tramways Trust for rails, fishplates, fastenings, roads, special work, and steel poles, at a total cost of £9,854. A 10 years' contract has been entered into with the Melbourne Electric Supply Company.

BARNSTAPLE.—The tender of Messrs. Malone, of Barnstaple, for the electric wiring of the workhouse buildings, at £122 10s., is recommended for acceptance.

BELFAST.—The tender of Messrs. Cowans, Ltd., Salford, for feeder panels for the lighting switchboard, has been accepted.

BURY.—Subject to the sanction of the Local Government Board for the necessary loan, a contract has been entered into with Messrs. Clarke, Chapman & Co., Ltd., for the supply of three water-tube boilers, each capable of evaporating 25,000 lbs. of water per hour, for the new electricity works.

CANADA.—Messrs. Jens Orten-Böving & Co. have received an order for two water turbines for the Calgary Electric Power Co., Calgary, Canada. The turbines have an output of 3,750 h.p. each.

The firm have also received an order for four Böving patent governors for four Francis turbines of 2,750 h.p. each for the Mines Power, Ltd. The consulting engineers in both cases were Messrs. Smith, Kerry & Chace, of Toronto.

DUNDEE.—The "D.P." Battery Co., Ltd., of Bakewell, have recently received an order for a storage battery of fifty cells for Dundee University College from Messrs. Steinthal & Boydell, Ltd., of Manchester and Bradford, who are supplying the whole of the electrical equipment of the college.

ECCLES.—The tender of Messrs. Waring & Gillow, of Manchester, has been accepted for the wiring of 12 houses at £48 15s.

HASTINGS.—The Electricity Committee recommend that new transformers be installed at certain sub-stations, and that application be made to the Local Government Board for sanction to the borrowing of the cost of the transformers, viz., £1,002. The estimated cost of making the alterations (£320) is to be defrayed out of revenue. In the event of the sanction of the Local Government Board being obtained a contract is to be entered into with the British Electric Transformer Co., Ltd., for the supply of transformers. The recommendation was adopted at the last meeting of the Corporation.

LEYTON.—For the electric wiring and fitting of the Syborn Street School, 25 tenders are received by the Council, ranging from £172 to £369.

LONDON: *Metropolitan Asylums Board.*—An order has been placed with the Electric Vehicle Co. for a 25-cwt. electrically driven lorry.

St. Pancras.—The Council have accepted the tender of the Sloan Electrical Co. for the annual supply of arc lamp carbons at £382.

LUTON.—The tender of Messrs. W. H. Allen, Son & Co., Ltd., of Bedford, has been accepted at £2,370 for a 500-kw. steam generator, and that of the Brush Electrical Engineering Co. for vacuum condensing plant at £780 10s.

UXBRIDGE.—A tender for the electric wiring and fitting of the workhouse and infirmary has been accepted by the Guardians at £110.

WEST HAM.—The Corporation received twelve tenders for the supply of six new tramcars, and accepted the following:—United Electric Car Co., Ltd., car bodies, £1,932; Brush Electrical Engineering Co., Ltd., electrical equipment, £1,161. An order has been placed with Mr. E. Peckham and the Anti-Magnolia Co., at £150, for the purchase of two trucks for the tramway undertaking, and the purchase of the material for five others, these to be constructed at the car sheds on payment of a royalty of £10 per truck to Mr. Peckham. The estimated cost of the seven trucks is £550.

WIMBLEDON.—B. & W. chain-grate stokers are to be installed on two boilers at the generating station at a cost of £600.

WOLVERHAMPTON.—The tenders of the Electric Construction Co., Ltd., for the supply of electrical fittings, at £289, has been accepted.

COMPANIES' MEETINGS AND REPORTS

OXFORD TRAMWAYS CO.—At the annual general meeting last week, it was stated that arrangements had been carried through with the Oxford Corporation and the City of Oxford Electric Tramways, Ltd., whereby the existing horse undertaking is to be vested in the latter. The terms are the paying off of £10,000 debentures, the allocation of £24,000 in shares in the new company, and the payment of a sum of £4,800 in cash or shares. The City of Oxford Electric Tramways, Ltd., has already paid off the £10,000 debentures.

SINGAPORE ELECTRIC TRAMWAYS CO.—At the annual meeting last week, the report and accounts given in our last issue were adopted. The Chairman, Mr. E. Davis, reported a satisfactory condition of affairs, both as regards tramways and electric supply, despite considerable trade depression during the year 1908.

METROPOLITAN DISTRICT RAILWAY CO.—The report for the half-year to June 30th states that the revenue continues to increase satisfactorily. During the past half-year the gross receipts amounted to £273,318, an increase of £25,419, whilst working expenses amounted to £148,096, being a decrease of £6,733. After providing for interest and other charges, and setting aside £10,000 as a reserve for renewals, the net revenue account shows a credit balance of £19,108, and the directors recommend a dividend at the rate of 3 per cent. per annum on the Four per Cent. Guaranteed stock.

LANARKSHIRE TRAMWAYS CO.—The revenue for the half-year ended June 30th amounted to £32,200, and the expenses to £17,686. After making contributions to local authorities, and meeting interest on debentures, and adding balance brought forward from December 31st, 1908, there is a balance of £13,976. A dividend of 5½ per cent. per annum for the half-year is recommended, and the balance of £5,283 is carried to revenue new account. The traffic receipts show a decrease of £1,764 as compared with the receipts for the corresponding half-year of 1908. The expenses, however, show a reduction of £1,306, mainly owing to the reduction in the car mileage, to the price of coal being considerably lower, and to the fact that this half-year no legal expenses have been incurred in connection with Parliamentary Bills affecting the company's interests. The directors will, as usual, provide for depreciation when the final accounts are made up at the end of the year. The meeting is on the 18th inst.

YORKSHIRE ELECTRIC POWER CO.—The receipts for the half-year ending June 30th last amount to £11,169, against £8,698 for the half-year ending June 30th, 1908, and £4,700 for the half-year ending June 30th, 1907. The gross profit amounts to £2,598, against a gross profit for the half-year ending June 30th, 1908, of £1,249, and £403 for the half-year ending June 30th, 1907. After payment of mortgage interest the net revenue account shows a profit of £1,070, compared with £363 for the corresponding half-year of 1908, and a loss of £1,211 for the half-year ended June 30th, 1907. It will shortly be necessary to instal further generating plant in the Thornhill power station. The whole of the issue of £45,000 of second mortgages has been applied for and allotted. The meeting is on September 21st.

LONDON, CHATHAM & DOVER RAILWAY CO.—At the half-yearly meeting last week, the Chairman, the Rt. Hon. Sir William Hart-Dyke, Bart., referring to short-distance traffic, said he hoped those who urged the electrification of their lines as a means of meeting tramway competition would really consider what the cost would be. The outlay would be enormous. Any such movement must be thorough and searching in its character; in his opinion it would be absolutely useless to experiment on a small portion of their system, because their competitors, being business men, would throw all their energies into meeting that small effort, and it would probably meet with disaster.

GREAT NORTHERN & CITY RAILWAY CO.—The Earl of Lauderdale presided at the annual meeting on Thursday, when the report and accounts, given in our last issue, were adopted. After going through the various items in the accounts, the Chairman said there was no use at each of their half-yearly meetings repeating the well-known difficulties under which they laboured owing to the persistent tramway competition. That competition had come to stay, and if they were to overcome the difficulties of the position, they could only do so by the excellence of their services, by the completeness of their through-booking arrangements, and by the facility given to long-distance suburban passengers for reaching the heart of the City. During the past half-year the Board had been giving full attention, so far as they could, to these matters. The tube railways of London were now working in close harmony by means of frequent meetings amongst the chief officials of those railways. This led to joint advertising, to a complete system of through-booking, and to the rectification of fares wherever possible in the interests of the tube railways. As they knew, their fares were governed by arrangements with the Great Northern Railway. The necessary notice to terminate this arrangement had just expired. They had not yet made any alterations owing to discussions which were in progress with the Great Northern company, and which might obviate any necessity for doing so, but until these negotiations culminated in some understanding one way or another, they had suspended making any change. Meanwhile the deficiency of £3,209 in their fixed charges had again been provided from the same sources as on the last occasion. The time for extending the line to the Bank, as sanctioned by Parliament expired next August, but the directors were not in a position yet to say whether application for an extension of the period should again be made.

CHILIAN ELECTRIC TRAMWAY & LIGHT CO.—The report for 1908 states that, after deducting interest and redemption of debentures, London office, and other charges, there is a balance of £8,832, to which must be added the balance brought forward, namely, £1,712, making a net balance of £10.545. From this sum £8,000 has been transferred to renewals reserve account, leaving a balance of £2,545 to be carried forward to credit of profit and loss account for the year 1909. The company has carried 68,342,366 passengers, earning $5,696.868, as against 61,451,234 passengers, earning $5,011,363 in 1907. The receipts for light and power during 1908 amounted to $3,681,118, as against $2,658,254 in 1907, showing a satisfactory development in this department; although the increased demands for power for tramway operations, as also for the extension of the public

Digitized by Google

lighting made it necessary for the company to partially limit the supply to the increasing demand for private lighting and power installations. However, it is hoped shortly to be able to meet all demands that may be made upon the company's power and lighting plant, with the advent of hydraulic power, the installation of which is nearing completion.

LONDON, BRIGHTON, & SOUTH COAST RAILWAY CO.—Presiding at the half-yearly meeting on Thursday, the Earl of Bessborough said the work of converting the Victoria-London Bridge section for electrical traction was nearly completed. A trial service of 16 trains had been running continually between Battersea Park and Peckham Rye, in each direction, for the last three months, and the full service between Victoria and London Bridge would commence on October 1st. The men had been receiving most careful training, both as regarded driving the trains and dealing with all the novel conditions of the system, and everything had worked most satisfactorily. They intended to open the public service between Peckham Rye and Victoria at the end of the month, but they had been careful not to start until the men had been thoroughly trained and tested. The consulting electrical engineer and the contractors had carried out the work in a most able manner, and were entitled to every praise for overcoming the many difficulties and obstacles with which they had had to contend. With the establishment of the full service between Victoria and London Bridge, a distance of between eight and nine miles, a very considerable acceleration in time would be effected between those termini, as where steam trains had taken 36 minutes, the electric trains would run in 24 minutes, with the same number of stops. A much more frequent service would be run, and both season ticket and ordinary rates would be revised to meet the new conditions. They hoped, therefore, that in a very short time they would regain some of the business which had been lost owing to the electric tram and motor-'bus competition.

CENTRAL LONDON RAILWAY CO.—At the half-yearly meeting on Thursday, the report and accounts given in our last issue were adopted, Sir Henry Oakley, Chairman of the company, who presided, dealt at some length with the question of fares. As far as could be seen there was a deficiency of £6,000 compared with the receipts derived last year from the Shepherd's Bush Exhibition, but the additional £14,000 to make up the loss in receipts of £20,000 for the half-year compared with the corresponding period of 1908, was due partly to bad trade, and partly to competition. There had been a very large increase in the number of workmen carried, and this could only be due to lack of trade, as there was no competition whatever for this traffic. Since adopting the graduated system of fares, the traffic had gradually come back. With regard to the Liverpool Street extension authorised by their Bill this year, the Board were confident that there was no point in London so full of traffic as that which centred at Liverpool Street from the Great Eastern, North London, and North-Western Railways, and were satisfied that there was a lucrative traffic to be derived from the centre when they were in a position to take advantage of it.

BAKER STREET & WATERLOO RAILWAY CO.—The receipts for the June half-year amounted to £91,510, an increase of £7,981 on the receipts for the corresponding half of last year. The working expenses amounted to £42,224, a decrease of £3,228. After providing for interest, rents, and preference dividend, and reserving £4,000 for contingencies and renewals, there remains a balance of £18,304, and the directors recommend a dividend of 1½ per cent. per annum on the ordinary shares, and an additional dividend at the rate of 1½ per cent. per annum (making 3 per cent. per annum in all) on the ordinary shares other than those held by the Underground Electric Railways Company of London, Ltd., or their nominees, leaving a balance of £5,105 to be carried forward. The number of passengers carried was 14,325,065, compared with 12,940,801 in the corresponding period of 1908, and the average receipt per passenger was 1·46d., compared with 1·48d. Referring to the rejection of the North West London Railway Bill by Parliament, which provided for the working by the Baker Street & Waterloo Co. of the projected railway from Edgware Road to Brondesbury, the report states that the policy of the company in relation to any future proposals which may be made by the North West London Railway Company as to constructing a railway from Edgware Road to Brondesbury is being considered. The extension to Paddington, which this company have power to construct, was so laid out on the Parliamentary plans that if it were constructed any extension beyond Paddington would be practically impossible, and its construction would also debar the company from arranging to work, as a continuous line, any extension in the direction of Brondesbury and Cricklewood, which, in the opinion of the directors, would be of more value than the Paddington extension. In these circumstances, the directors recommend that the Paddington extension, as authorised, should be abandoned, and all questions as to extension of the railway beyond Edgware Road left for future consideration. The meeting is to-day.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—The receipts for the June half-year amounted to £157,993, an increase of £10,229 on the receipts for the corresponding half of last year. The working expenses amounted to £73,404, a decrease of £1,579. After providing for interest, rents, and preference dividend, and reserving £6,000 for contingencies and renewals, there remains a balance of £33,592, and the directors recommend a dividend at the rate of 1 per cent. per annum on the ordinary shares, leaving £8,352 to be carried forward. The number of passengers carried was 19,155,883, compared with 17,446,477 in the corresponding period of 1908, and the average receipt per passenger was 1·89d., compared with 1·95d. The meeting is to-day.

LIVERPOOL OVERHEAD RAILWAY CO.—The receipts for the June half-year amounted to £35,188, and the working expenses to £27,372. After meeting interest on mortgage debentures and adding the balance brought forward, there is a sum available of £7,696. Out of this balance the directors recommend a dividend at the rate of 5 per cent. per annum on the (1892) preference shares (less income tax), leaving a balance of £4,696 to be carried forward to next half-year. The receipts for passenger traffic have declined during the half-year by £2,486, which is mainly attributed to depression in trade. Working expenses, however, have been decreased by £3,138. The number of passengers carried was 4,900,216, against 5,167,464 in the previous half-year, and 5,367,286 in the June half-year of 1908. The meeting is on the 17th inst.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—The receipts for the half-year to June 30th amounted to £105,182, being an increase of £16,299 on the receipts for the corresponding half of last year. The working expenses amounted to £57,795, an increase of £1,302. After providing for interest and rents, and reserving £3,000 for contingencies and renewals, there remains a balance of £18,813, and the directors recommend a dividend at the rate of ¾ per cent. per annum on the ordinary shares, leaving £2,590 to be carried forward. The number of passengers carried was 14,862,882, against 12,132,639 in the corresponding period of 1908; and the average receipt per passenger was 1·63d., against 1·67d. The meeting is to-day.

WESTINGHOUSE ELECTRIC & MANUFACTURING CO.—The accounts of the Westinghouse Electric & Manufacturing Company (the parent concern) have just come to hand. The affairs of the company were taken out of the hands of the receivers in December, 1908. The present board was elected November 30th, 1908, the officers were appointed December 7th, 1908, and an executive committee elected January 5th, 1909; but the Board was not permanently organised until the election of Mr. Robert Mather as Chairman, January 19th, 1909. There was a decrease in the surplus account during the year ended March 31st last of $2,992,662, as follows:—Loss from operations of the business after providing for all interest charges and making fair allowances for depreciation, $918,683; expenses incurred in connection with the adjustment of the debt existing October 23rd, 1907, $460,490; compensation and expenses of receivers and their attorneys, $265,883; charged off to reduce the book value of assets, such as discount and expenses incurred in connection with bond issues of previous years; depreciation of patents, depreciation of various stocks and bonds, provision for possible losses on inactive finished parts and machines on hand at the close of the year, and other minor items of similar nature, $1,347,606. The loss during the fiscal year of $918,683, after providing for interest on the debt and all expenses, is chiefly accounted for by a small volume of business, the utilisation of high-priced material, by sales at reduced prices and by very considerable extra expenses incurred in completing the departmentalising of the manufacturing operations of the company, and in the rearranging of the machinery, which work was carried on without interruption by the receivers. These important changes in manufacturing methods have reduced greatly the amount of raw material, in process and finished, required to be kept in stock for a given amount of output, and has also increased the space available for manufacturing operations. While there has been a decided improvement in the business of the company since the beginning of the year, it has not yet nearly reached normal proportions, although the outlook and inquiries indicate that in the near future the full capacity of the various works will be required to meet the demand.

GREAT NORTHERN RAILWAY CO.—At the half-yearly meeting on Tuesday, the chairman, Lord Allerton, said he was very sceptical as to railways being able to compete effectively with electric tramways for short-distance traffic, owing to the facilities which the latter offered for picking up passengers and setting them down again locally. He had therefore come to the conclusion that the directors' energies could be better applied than in endeavouring to break up tramway authorities or ruining themselves over the short-distance passenger. So far as the Great Northern Co. was concerned, it would appear that tramway competition had done its worst, for at a good many stations their receipts showed either a small increase or an extremely small decrease.

MISCELLANEOUS CITY NOTES

CONSOLIDATED ELECTRICAL CO.—A dividend of 3 per cent. per annum, less tax, is declared upon the ordinary shares, carrying £7,385 forward.

WASTE HEAT & GAS ELECTRICAL GENERATING STATIONS.—An interim dividend of 5 per cent. per annum, less tax, is declared.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 to £60 10s. (last week, £60 5s. to £60 15s.).

ORTEN-BOVING CENTRIFUGAL PUMPS.—Messrs. Jens Orten-Böving & Co. have received a further order for two of their centrifugal pumps to deliver 200 gallons per minute against a head of 535 feet at 1,440 r.p.m. The main contractors for the work are the British Westinghouse Electric and Manufacturing Co., Ltd., and the consulting engineers Messrs. Rendel & Robertson. The features of these pumps, which are being manufactured by Messrs. Willans & Robinson, Ltd., are an automatic end-thrust balancing device, improved designs of impellers and guide wheels, and casing, &c.

NEW "SIMPLEX" METAL FILAMENT LAMPS.—Simplex Conduits, Ltd., notify us that they can now supply high voltage lamps suitable for burning direct on circuits from 200-250 volts of 25 c.p. The price of these new lamps will be 4s., and delivery can be effected in about a fortnight's time.

DISSOLUTIONS OF PARTNERSHIP.—E. Sharp and A. Waters, carrying on business as electrical engineers at 34 Uverdale Road, Chelsea, London, have dissolved partnership. Debts by E. Sharp.

L. W. Holmes has retired from the firm of Messrs. J. H. Holmes & Co., electrical engineers, Newcastle-on-Tyne.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Creditors of Messrs. Thomas Parker, Ltd., in voluntary liquidation, are requested to send particulars of their claims to the liquidator, Mr. W. A. Nelson, Lichgate, Wolverhampton, by August 28th.

Creditors of the General Electric Sign & Engineering Co., Ltd., are requested to send particulars of their claims to the liquidator, Mr. E. Hayes, 28 Basinghall Street, London, E.C., by September 7th.

A second and final dividend of 9½d. in the £ will be paid on August 18th at 1 Bank Street, Bradford, in the bankruptcy of W. T. Garnett, trading as Garnett's Cable Co., Barkerend Mills, Bradford.

NEW COMPANIES

WALTER SCOTT & CO. (EDINBURGH).—Registered in Edinburgh on July 8, with a capital of £500, to acquire the business of electrical, mechanical, and general engineers carried on at 148 Rose Street, Edinburgh, as Walter Scott & Co. Registered office, 148, Rose Street, Edinburgh.

PREMIER ELECTRIC INSTITUTE.—Registered on July 9, with a capital of £100, to inaugurate an institute for selling curative electrical appliances and advising on electrical treatment. Registered office, 133-5, Regent Street, W.

LIGHTING.—Registered on July 21st, with a capital of £1,000, to carry on the business of manufacturers of, and dealers in, lamps, burners, parts, and apparatus for lighting and other purposes, electricians, engineers, &c. Registered Office: 25 King Street West, Manchester.

FILAMENTS.—Registered on July 19th, with a capital of £500, to adopt an agreement with J. W. H. Reynolds, for a secret process for the manufacture of metal filaments for electric lamps. Registered Office: 6 Newcastle Street, E.C.

CHIPPENHAM ELECTRIC SUPPLY CO.—Registered on July 19th, with a capital of £5,000 in £1 shares (2,500 5 per cent. preference), to adopt an agreement with the Chippenham Corporation, and to carry on in Chippenham and elsewhere in Wiltshire the business of suppliers of electric light, electricians, engineers, &c. The subscribers are J. H. Edwards, 127, Victoria Street, Bristol, electrical engineer; E. Neale, 10 High Street, Chippenham. Registered by Waterlow Bros. & Layton, Ltd., Birchin Lane, E.C.

ALBA LAMP SYNDICATE.—Registered on July 29th, with a capital of £3,000 in 2,925 preferred ordinary shares of £1 each and 3,000 deferred ordinary shares of 6d. each, to acquire the benefit of and develop and turn to account a certain existing invention relating to a central reflector electric lamp. Registered office: 149-150 Finsbury Pavement House, E.C.

CHAS. E. GOAD.—Registered on July 26th, with a capital of £6,000, to take over so much of the business of making surveys and preparing plans for insurance companies, survey and plan work generally, and civil and electrical engineering carried on by C. E. Goad from 53 New Broad Street, E.C., and elsewhere, except Canada and Newfoundland. Registered office: 53 New Broad Street, E.C.

SYLVERLYTE (1909).—Registered on July 24th, with capital of £200,000, to acquire any inventions relating to electric and other lamps, or any lenses, reflectors, or other component parts or accessories for use in connection therewith, in particular to acquire patents No. 5,191 of 1904 and 10,696 of 1908; also to acquire the business and assets (except cash in hand) of the Sylverlyte Electric Lamp Co., Ltd. Registered office: 13 Sise Lane, Queen Victoria Street, E.C.

TRACTION SUPPLIES CO.—Registered on July 28th, with a capital of £5,000, to carry on the business of electricians, electrical engineers, manufacturers of and dealers in fittings and accessories used in connection with electric traction, lighting, or heating, &c. Registered office: Gill Bridge Avenue, Sunderland.

ELECTRICAL ENGINEER.—Registered on July 29th, with a capital of £1,500 in 1,425 preferred ordinary shares of £1 each and 1,500 deferred shares of 1s. each, to acquire the rights and property in connection with the newspaper or periodical known as the *Electrical Engineer*, to adopt an agreement with C. S. Sarle, and to carry on the business of newspaper and magazine proprietors and general printers and publishers, advertising agents, &c. The subscribers are:—C. S. Sarle, 38 The Avenue, Brondesbury Park, N.W., journalist; G. Cadogan-Rothery, 5 Fetter Lane, E.C., journalist. Private company. The number of directors is not to be more than five. The first are H. A. Gwyne, G. Cadogan-Rothery, and C. S. Sarle. Remuneration as fixed by the company. Registered office: 149 Fleet Street, E.C.

PACIFIC RAILWAY COMPANY OF COLOMBIA.—Registered on July 30th, with a capital of £280,000 in £20 shares, to acquire or construct railways, light railways, tramways, &c., in the Republic of Colombia or elsewhere, and in the first instance to acquire as a going concern the undertaking and assets and liabilities of the Compania del Ferrocarril del Pacifico (formed under the laws of the Republic of Colombia), including all concessions granted to the company by the Government of the said Republic for the construction and operation of lines of railway, to operate any of the company's railways by steam, electricity, or other power, &c.

BARBADOS ELECTRIC SUPPLY CORPORATION.—Registered on July 30th, with a capital of £60,000 in £1 shares (40,000 7 per cent. preferred and participating), to adopt agreements with the Anglo-American Debenture Corporation, Ltd., and to carry on the business of electricians, mechanical engineers, suppliers of electric, water, and other power, manufacturers of and dealers in apparatus used in connection with the generation, supply, utilisation, and distribution of electricity, &c. Registered office: 24 Martin's Lane, E.C.

PARLIAMENTARY INTELLIGENCE

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL.—We give on another page particulars of some amendments to this Bill, of which notice has been given for the third reading in the House of Commons.

PROGRESS OF ELECTRICAL BILLS.—The Watford Urban District Council Bill and the Oldham Corporation Bill were read a third time and passed in the House of Lords on Wednesday last week. On Thursday the Greenock Corporation Bill was read a third time and passed in the House of Lords.

GLASGOW CORPORATION BILL.—On Wednesday last week the Court of Referees of the House of Commons allowed a *locus* to the Caledonian & Lanarkshire & Dumbartonshire Railway Companies, North British Railway Co., Glasgow & South-Western Railway Co., and Caledonian & Glasgow and South-Western Railway Companies against the tramway clauses of this Bill.

APPOINTMENTS AND PERSONAL NOTES

R. D. Archibald, B.Sc., late principal assistant to Dr. Magnus M'Lean (Glasgow and West of Scotland Technical College), has been appointed lecturer in electrical and mechanical engineering at the new Technical College, Dundee.

At a meeting of the Council of the Leeds Local Section of the Institution of Electrical Engineers, held at the Hotel Metropole on May 17th, 1909, Mr. W. M. Rogerson, Chairman of the Section, presiding, it was resolved that in view of the approaching marriage of the Honorary Secretary, Mr. Harold Dickinson, and as some acknowledgment of his valuable services in founding the Leeds Section of the Institution of Electrical Engineers, and as its first Chairman, together with the keen interest displayed by him in the interests of the Section as Honorary Secretary, and as a tribute of the high esteem in which he is held by all the members, a suitable wedding gift should be presented to him. The presentation was made on Thursday, August 5th, 1909, when an ornamental silver table centre was presented to him.

Mr. Chas. T. Linney, manager and resident engineer of the Kent Electric Power Co., has been presented with a silver salver and silver cigarette case as a token of esteem and goodwill from the directors, staff, and employees of the company on the occasion of his leaving the company's service.

On Saturday last, Mr. J. E. Sayers, of Messrs. Sayers & Caldwell, consulting electrical engineers, Glasgow, was married to Miss Margaret Wilson.

Mr. H. A. Howie, deputy electrical engineer at Wolverhampton, has been appointed chief assistant electrical engineer at Sheffield.

The Wolverhampton Corporation recommend a rearrangement of the electricity works staff, consequent upon the appointment of Mr. Howie, deputy electrical engineer, to Sheffield, as follows:—Technical and general assistant, Mr. E. Stubbs, £160 per annum; maintenance engineer, Mr. J. S. Dudley, £156 per annum; boiler-house superintendent, Mr. C. Bellhouse, £125; engine-room superintendent, Mr. E. Forder, £120; a draughtsman (temporary), £104; junior assistant, Mr. F. C. Platt, £85.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

We regret to record the death of Mr. Hugh Erat Harrison, principal of the Electrical Standardising Testing and Training Institution, Faraday House, and of Mr. M. Wilson, of the Electrical Standards Laboratory of the Board of Trade. (Page 734.)

Mr. W. J. U. Sowter replies to Mr. G. W. Partridge's letter relating to the subject of bonding and earthing, and describes an experience on the Bray electric lighting system, which bears out Mr. Partridge's remarks with regard to the insufficiency of the usual earth plates for obtaining a good earth connection. A correspondent writes asking for more particulars relating to a recent communication on the comparative costs relating to the substitution of running electric motors and gas engines. (Page 735.)

A large electrolytic hydrogen plant for balloons has recently been erected for the United States Army. (Page 735.)

Short articles describe an electrically-driven fire pump, some new fittings for tungsten lamps, and a new controller in which breaking the circuit on the drum contacts is avoided. (Page 736.)

As a result of inquiries which we are constantly receiving as to the education of those intending to enter the electrical engineering profession, we are publishing some particulars of the courses of instruction in electrical engineering which are given at the various universities, colleges, technical institutes, &c., about the country. Particulars are given in this issue of the Electrical Engineering courses at Cambridge and Oxford, and the leading universities, colleges, and technical schools in the provinces, indicating, where possible, the previous education expected, the length and nature of the course, the fees, and the degrees or certificates that can be taken. The colleges, &c., in London will be dealt with next week. (Page 737.)

The new 90-ton continuous-current locomotives for the Detroit River Tunnel, U.S.A., are of the double-truck articulated type, provided with four 300-h.p. motors, with forced ventilation, and equipped with multiple unit control. (Page 740.)

Digitized by Google

The following books are reviewed in this issue:—"Electric Lamps," by Maurice Solomon; "The Calculus and its Applications," by R. G. Blaine; "Japanese Patents," by H. S. Bickerton Brindley; "Engineering Units of Measurement," by J. Ramsay; and "The Engineering of Ordnance," by A. Trevor Dawson. (Page 741.)

In consequence of the increased demand for electric power in Launceston, Tasmania, an extension to the present generating capacity is required. The city engineers have drawn up a report containing four alternative schemes. The first consists in the erection of a new water-power station, the second provides for the installation of an auxiliary steam or gas-engine plant in the city to assist the present water-power station, and the other two consist in the extension of the present water-power station by building a new dam and enlarging the tunnel, or constructing a second tunnel, and installing additional generating plant. The estimated costs of these alternative schemes are given. (Page 742.)

The report of H.M. Inspectors of Mines on the West Stanley Colliery disaster throws little further light on the cause of the explosion, but electricity is mentioned as a probable first cause. Mr. Nelson, H.M. Electrical Inspector of Mines, adds some important recommendations relating to electrical apparatus in mines, in an appendix to the report. (Page 742.)

Universal penny fares have been adopted upon the Aberdeen Corporation tramways as an experiment.—A Royal Commission have approved of the construction of tube railways under Sydney Harbour.—The net profits from the Bradford Corporation tramways for the past year were £15,318, compared with £17,238 in the previous year.—The Devonport magistrates have decided against the local tramway company on the summonses taken out by the Corporation for not running cars on the leased lines.—Owing to special capital charges, the accounts of the Glasgow Corporation electricity undertaking for the past year show a loss of £3,108.—A net profit of £36,635 is shown by the Sheffield Corporation tramway accounts for 1908-9. British and Japanese capitalists are reported to be combining in order to develop a number of water-power electric generating stations in Japan. (Page 743.)

A turbo-alternator is required by the Plymouth Corporation, and cables by the Leeds Corporation.—The Barnsley Corporation propose to borrow £3,000 for electrical purposes.—An electrically-driven watering cart is required by the cleansing department of the Dublin Corporation. (Page 744.)

A 10 per cent dividend is declared by the Chloride Electrical Storage Co., Ltd., 2 per cent. by Messrs. Crossley Bros., and 4½ per cent. on the "B" ordinary shares of the Northampton Electric Light & Power Co. (Page 745.)

In a Paper read before the American Institute of Electrical Engineers, Messrs. H. G. Reist and H. Maxwell described the different methods of obtaining two or more efficient speeds with three- and two-phase induction motors, and gave a list of the most suitable arrangements under different conditions. (Page 747.)

A novel heavy current mercury ammeter, depending on the tendency of liquid conductors to be attracted towards the centre, has been developed in America. (Page 748.)

The principal features of the "pendulum" suspended tramcar trucks and new radial trucks of the Peckham Truck Co. are outlined (Page 749.)

Recent researches in America by Dr. C. P. Steinmetz have shown that the watts taken by a tungsten lamp vary with the 1·6th power of the impressed voltage. (Page 749.)

Among the specifications published by the Patent Office on Thursday last are two relating to shade carriers or holders for incandescent lamps by W. A. Hill, and J. Nelson and Drake & Gorham, Ltd., respectively. In both cases, the shade is pressed up against the collar on the lamp-holder by means of a spring.—A circuit-breaker in which the series solenoid is mounted on the switch-arm, and is connected in series between the fixed contacts when the switch is closed, is protected by the British Thomson-Houston Co., and a specification by Siemens Bros. Dynamo Works describes a circuit-breaker for placing between the sections of traction systems. When a fault occurs, the circuit-breaker operates, but puts in circuit a resetting switch which automatically closes the breaker directly normal conditions are restored.—The Nya Ackumulator Aktiebolaget Jungner have taken out a patent for a graphite plate for alkaline storage batteries.—In spite of opposition, patents have been granted to J. C. Bowie and J. H. Phelps, and to W. Timbrell and C. E. Gabriel for an igniter for miners' lamps and a tramcar life-guard respectively.—The opposition to the grant of a patent to the "Z" Electric Lamp Syndicate for a process of manufacturing metal filaments has been withdrawn.—Application has been made for the revocation of a patent by W. Claypoole for an insulating composition, and A. R. Raymer desires to have a lapsed patent relating to a method of cleaning out boilers under pressure, restored. (Page 750.)

OBITUARY

Hugh Erat Harrison.—We regret to note that Mr. H. E. Harrison, Principal of the Electrical Standardising, Testing, and Training Institution, Faraday House, London, died last Thursday at the age of 50. Death was attributed to an overdose of a narcotic taken to relieve severe internal pain from which Mr. Harrison occasionally suffered. At the inquest, held in Marylebone on Saturday, the jury returned a verdict of death by misadventure. Mr. Harrison was educated in London and Paris, and after taking his degree in 1880, entered the service of the Anglo-American Brush Co., and afterwards was appointed managing engineer of the Sheffield branch of the Hammond Electric Light & Power Co., Ltd. In 1882 Mr. Harrison organised and became Principal of the latter company's Electrical Engineering College in Red Lion Square, London, and when it was closed in 1885 he became a partner in the firm of Phillips, Harrison & Hart. On retiring from this firm, he was appointed Clerk to the Research Committee of the Institution of Mechanical Engineers, and then in 1889 he founded the Electrical Standardising, Testing, and Training Institution, Faraday House, with which his memory will be chiefly associated. In 1904 Mr. Harrison attended the St. Louis Congress as one of the delegates of the Institution of Electrical Engineers, and he has twice been elected a member of the Council. He has contributed to the technical Press, and has written two small books for the use of Faraday House students. Although a man of wide reading and clear judgment, Mr. Harrison was most reserved and nervous, and, consequently, was not so well known personally as his position and abilities might have led one to expect.

M. Wilson.—Those who have had dealings with the Electrical Laboratory of the Board of Trade will learn with regret of the death, after only one day's illness, of Mr. M. Wilson, senior. He had served in the R.E. as a Sapper for over 21 years, and held for seven or eight years the office of storekeeper whilst acting as laboratory assistant at the Chatham School of Military Engineering under Major P. Cardew. He has held the office of assistant electrician and mechanic to the Board of Trade Electrical Standards Laboratory since its inception in 1890, and the wide range of practical knowledge which he brought to bear on his duties made his services highly appreciated by all with whom he came into contact.

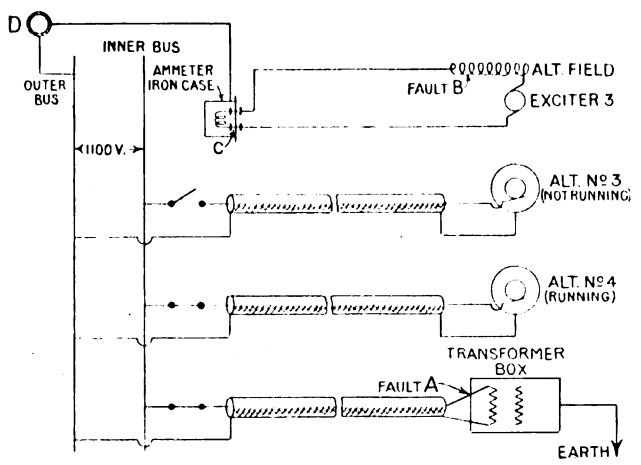
CORRESPONDENCE



BONDING AND EARTHING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have read with great interest Mr. G. W. Partridge's letter on the above subject (see ELECTRICAL ENGINEERING, August 12th, page 717). With regard to the diagram which accompanied my article on the same subject, I regret that I erroneously showed a fuse on the outer conductor. While most of our transformers are provided with a H.T. fuse fitting for each pole, I have, in the case of the fitting for the outer conductor, inserted a heavy piece of copper instead of a fuse, as I am fully aware of the risk one runs in putting a fuse in circuit with any conductor which is connected to another conductor at earth potential.

I am particularly interested in Mr. Partridge's safety device, as depicted in Figs. 2 and 3, which is manifestly vastly superior to the ordinary method which he shows in Fig. 1. His device has the merit that, should the connection to earth fail at the point *B*, he still has a protection afforded by the spark-gaps *C* and *D*, together with a low resistance conductor back to the generator. I shall hope to try his method when the opportunity occurs.

I have had similar experience to Mr. Partridge regarding the inadequacy of earth connections when dealing with considerable currents, and even on our

small system here, I had rather an extraordinary occurrence of the sort a short time since. The system is single-phase 1,100 volts, concentric feeders with outer bus-bar earthed to a pipe laid under the bed of the river adjacent to the works. The iron frame of the switchboard is also earthed to the same pipe by a substantial conductor. The iron-cased ammeters in connection with the field-circuits of the alternators are bolted to vertical iron rheostat pillars, which in turn are bolted to the iron frame of the switchboard, thus being well earthed.

A fault occurred on an inner conductor where it entered the iron case of a transformer, situated about half a mile from the generating station, causing a bad short, and tripped the time-limit relay controlling the particular feeder affected. A flash was noticed inside the case of the exciter ammeter of No. 3 generator (which was not running at the time) each time the feeder switch was put in. It was subsequently discovered that the field winding of No. 3 alternator had gone to earth, and an arc had occurred between the exciter ammeter case and the terminal plate, which were separated by a piece of fibre about $\frac{1}{8}$ in. thick. The accompanying diagram shows the part of the system affected. It is curious that part of the leakage current preferred to follow the path *A B C*, and leap across what was practically a spark-gap at *C* in preference to passing through the earth connection and thence, *viâ* the earth, to the bus-bar at the generating station. I subsequently tested the earth connection between *D* and a similar pipe a few yards away, and found the resistance was 6·2 ohms.

I shall be interested to hear whether Mr. Partridge uses earth shields in his transformers, or whether he depends solely upon an earth connection on the L.T. side, together with his spark-gaps between the H.T. outer and the L.T. system.

Yours faithfully,
WM. J. U. SOWTER.

Electricity Works, Bray, August 13th, 1909.

ELECTRIC MOTORS v. GAS ENGINES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In your issue of August 5th, a correspondent gives some very interesting figures showing a considerable saving by substituting electric motors for a gas engine. These figures would be much more valuable if your correspondent would be kind enough to furnish the following additional particulars :—

1. Cost of gas per thousand feet.
2. Cost of electricity per unit.
3. H.P. of gas engine.
4. Number and h.p. of the motors.
5. Total outlay for the electric installation.
6. Original cost of gas engine and its age.

Without this information it is impossible to estimate fully the commercial advantage of the change.

Yours faithfully,
Ipswich, August 11th. W. O. HORSNAILL.

ELECTROLYTIC HYDROGEN PLANT FOR BALLOONS

AN electrolytic hydrogen plant has been erected by the United States Army Signal Corps, at Fort Omaha, in Nebraska, in connection with a large new balloon house which has been established there for experiments with dirigible and other balloons. According to the *Electrical World*, a 200-kw. motor generator, taking current from an electric light and power company in the neighbourhood, has been installed. This converts the alternating supply to continuous current at from 66 to 110 volts. The hydrogen is generated by electrolysis in cast-iron cells containing caustic potash electrolyte. There are 30 of these cast-iron electrolytic cells, all connected in series. The voltage required varies according to the temperature of the cells, hence the wide range of voltage for which the generator is designed. The operating voltage when the cells are warmed up is 85 volts for the 30 cells, or 2·8 volts per cell. The cells are rated at 1,500 amp. The output of hydrogen at 1,500 amp. is about 23 cu. ft. of gas per hour, or 690 cu. ft. for the 30 cells. Both of the electrodes are of iron. The iron case of the cell forms the negative electrode from which the hydrogen is obtained. The positive electrode, which gives off oxygen, is in the shape of an iron cylinder in the cell. Hydrogen gas, which collects above the negative electrode, is taken to a 50,000-cu.-ft. gas holder. The oxygen is allowed to escape into the air because the United States Army is not allowed to sell by-products. Besides generating hydrogen for use in the balloon trials from Fort Omaha, preparations are being made to bottle the hydrogen generated here for shipment to other points where the signal corps of the army may wish it for balloon purposes. The bottles used are of steel, capable of withstanding 3,000 lbs. pressure to the square inch. The compressors for compressing the hydrogen and testing the steel bottles are motor-driven.

Fire at the Witton Works of the G.E.C.—On Saturday evening a fire broke out in one of the testing sheds of the General Electric Co.'s works at Witton. The Aston Fire Brigade succeeded in keeping the outbreak from extending to the adjacent store rooms, but it appears that some considerable damage has been done to the test room itself.

Cable Damaged during Road Excavation in Bermondsey.—Some workmen, engaged in road excavation on Saturday morning, accidentally drove a wedge into a 0·1 sq. in. distributer of the cable network of the Bermondsey electric light and power system. The resulting short-circuit caused the cable to catch fire, and the gases given off from the heated insulation passed through the ducts to two cable boxes, and were there ignited. The boxes and the pavement round them were considerably damaged by the explosions, as well as the cables themselves, but the damage was soon repaired. No one was near the two boxes at the time of the explosions, and none of the workmen were injured.

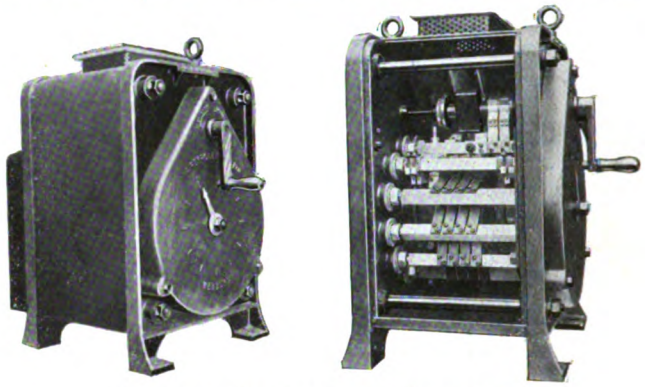
AN ELECTRICALLY-DRIVEN FIRE PUMP

THE accompanying illustration shows a powerful electrically-driven fire pump, which has recently been constructed by Messrs. Merryweather & Sons, of London, to the order of the Great Eastern Railway Co., for the protection of Parkeston Quay. The pump is of the makers' patent "Hatfield" type, having three gun-metal plungers working through packed glands directly in the valve chambers, and arranged 120° apart round a common crank-shaft. The pump can draw from a depth of 27 ft. without the aid of priming devices. Each plunger is fitted with a tail rod, working through a stuffing-box in the valve cover. The pump is capable of delivering 500 gallons of water per minute when running at a speed of 220 revolutions per minute, and is driven from an electric motor by means of a silent chain, enclosed in a dust-proof and oil-tight case. The electric motor is shunt-wound, of 52 b.h.p., and is provided with a large iron-clad switch and "foolproof" starter. The pump and motor are fitted on a channel iron frame, the motor being on sliding rails, enabling the tension on the chain to be adjusted.

The machine is designed to give a maximum pressure of 100 lbs. per square inch at the pump. It is fixed on the quay-side, and a connection is made from the delivery to a 6-in. main, which is led round the quay, and upon which hydrants are fixed at suitable intervals. In addition to this, there is an independent connection for hose direct on the pump, for coping with fires in the immediate neighbourhood. The suction is taken from the river through a 6-in. cast-iron pipe, about 60 ft. long, the lower end of this pipe being fitted with a foot valve and strainer. The maximum lift at low tide is 24 ft. The pump is, of course, always ready for instant starting, and, as will be seen from our illustration, the installation is very compact, considering the quantity of water delivered.

Electrically-driven "Hatfield" Pump for Fire Protection.

NEW TUNGSTEN LAMP FITTINGS



A NEW series of designs of fittings for groups of several tungsten lamps is being introduced by the British Thomson-Houston Co., of Rugby. With these a powerful light equal to that of a small arc lamp, but softer, can be obtained without the attendant troubles of carboning and trimming. The devices are artistic and most effective for shop, ship, hall, or club-room lighting. They are made of copper or zinc, with a standard finish of oxidised copper, and the globes, which are supplied either plain or pocketed, are of flint glass, ground on the inner surface.

They are made with plain shades or shades with pockets for each lamp, and can be arranged for fixed suspension with ceiling plate from hooks, with or without chains, or rigidly from ornamental iron brackets. Both four-lamp and six-lamp fittings are made.

Electric Railways in 1908.—The annual Board of Trade statistics relating to railways show that at the end of 1908 the length of line (in equivalent of single track) worked solely by electricity was 204½ miles, and that 200½ miles were being worked partly by electricity. The corresponding lengths of line at the end of 1907 were 196¼ and 182¼ miles respectively. The total quantity of electrical energy used in 1908 was 249,287,308 Board of Trade units, as compared with 213,675,447 in 1907.

THE REYROLLE "MONO-BREAK" CONTROLLER

MESSRS. A. REYROLLE AND CO., LTD., of Hebburn, have now put on the market a type of controller which will be of very considerable interest to electrical engineers, on account of the special features in its design. Leaving the liquid type of controller out of the question, it is well known that the ordinary pattern consists, in effect, of a drum carrying contacts which engage with a number of contact fingers, the breaking-points being under the influence of a more or less powerful magnetic blow-out. In Messrs. Reyrolle's new controller, however, contact is broken on one pair of fingers only, and it is obvious that this allows of an exceedingly powerful magnetic field being concentrated in the particular breaking-point. The illustration is of a controller of the 600-amp. size, with nine controlling positions, in addition to an "off" position and "full-on" position.

New Reyrolle Mono-break Controller.

The handle shown is on the same spindle as the contact-maker, and the jaws of the blow-out magnet can clearly be seen just above the latter. For each half revolution of the handle, the main drum advances 1/12 of a revolution, and during this period a step of the resistance is either cut in or out of circuit, but, of course, there can be no sparking, except at the contact-maker.

It may be said that, under ordinary conditions, the main contacts will practically never require renewal, and, on account of the powerful blow-out effect provided, wear on the breaking-contact is exceedingly small, but in any case the cost of renewal is almost negligible, and replacements are easily effected. Messrs. A. Reyrolle & Co. apply the mono-break principle to all sizes of controller, and we understand that they will shortly be in a position to quote for all sizes.

Dispute *re* Newfoundland Cable.—A breach of faith on the part of the Newfoundland Administration with the Commercial Cable Co. of New York is alleged. It is asserted that the Commercial Cable Co. made a contract with the previous Administration of Newfoundland, providing for the landing of a new cable at St. John's, and on the strength of that contract invested upwards of £200,000. Now, it is represented, the present Newfoundland Government does not recognise the contract as binding, and offers obstacles to the operation of the cable. Sir Edward Morris, the Newfoundland Premier, denies that there has been any breach of faith, or that the Government of Newfoundland does not recognise the contract, or that it is in any way offering obstacles to the laying of the cable. The Government of Newfoundland does not, he continues, refuse to ratify agreements entered into. It did, however, refuse without ample consideration to bring before the Legislature for ratification this contract, principally for the reason that it was unfair and prejudicial in many respects to the Anglo-American Telegraph Co., Ltd., and would create in favour of the Commercial Cable Co. a monopoly for twenty-five years of the transmission of all cable messages passing over the Newfoundland Government land lines. The Commercial Cable Co., under its agreement made in 1905 with the Newfoundland Government, are now bringing in their cables. There is no objection to this, but the Government have not felt justified in granting by Act of Parliament the further concession attempted to be given in the agreement of 1909—namely, a monopoly for twenty-five years and freedom from taxation.

ELECTRICAL ENGINEERING EDUCATION

At this period of the year we receive occasional inquiries from prospective electrical engineers or their parents, asking us to recommend the best course to pursue for entering the electrical engineering profession. The number of universities, colleges, and polytechnics in this country at which technical education can be obtained is now so great that we have thought that it would be useful to publish an article giving some particulars of the course of instruction given at each of these institutions, the previous education expected of students desiring to enter, the length of the course at the college, and the degrees or certificates conferred. It is well known that an electrical engineer's education cannot be completed by college training alone; a period of pupilage or apprenticeship at an engineering works is essential, and this can either be taken before or after the college course, or "sandwiched" between two or three periods spent at the college, according to which method would be best suited to the physical and mental aptitude of the particular student. The choice of the works in which the practical part of the training is to be given is usually decided by the special circumstances of each case, but in the selection of a suitable college, students or their parents are presented with almost an *embarras de richesse*, so that we believe that the present article bringing out the main objects and features of the training at each of the various colleges will be welcome.

I.—THE UNIVERSITIES OF CAMBRIDGE AND OXFORD.

Those who go to Cambridge or Oxford on leaving school need not defer the commencement of their special engineering education until their time at the University is finished. At both Universities a degree is now open to engineering students. It must not be forgotten, however, that the age for entering these Universities is at least eighteen or nineteen, so that those who go through the engineering courses there will be rather late in finishing their technical training if they then have still to serve their time in engineering works. In some cases, therefore, it may be preferable for the student to work for a short period in the shops, and possibly also to attend elementary technical classes before entering college.

The University of Cambridge.

The laboratories of the engineering department of Cambridge University are open to, and the lectures may be attended by, any matriculated member of the University, whether he be a member of a particular college or not, and no examinations are necessary for this, although some of the colleges have entrance examinations of an elementary nature of their own. In order, however, for him to take the mechanical sciences "tripos" examination, which, like the tripos examinations in other subjects, qualifies for the honours B.A. degree, he must pass the "previous examination" in general subjects (including classics). It is not necessary for him to do this on entry; he may take it at any time before he goes in for the tripos examination. He must also pass the qualifying examination in mathematics and mechanics at the end of his first year.

The most important feature of the training obtained at Cambridge is, of course, the fact that the student has to reside there for three years, and this is found in practice to be a great advantage in after-life, the value of which is now fully realised by many employers. The main object of the training is to make it of such a character that it will be of real educational value, even to one who is not going to take up engineering as his profession. Thus a great deal of attention is devoted to teaching scientific principles, utilising the practical applications of these principles, however, wherever possible by way of illustration, so that a student acquires practical knowledge without in any way sacrificing the general liberal education which Cambridge is supposed to give.

Prof. J. A. Ewing, F.R.S., was for some time Professor of Mechanism and Applied Sciences, and was succeeded by Prof. B. Hopkinson, who is assisted by a number of lecturers and demonstrators. The electrical work is mainly under the charge of Mr. C. G. Lamb.

All students, whatever branch of the profession they intend to enter, go through the same course as far as the elementary work is concerned; but a certain amount of specialisation is permitted to those who can take the advanced papers.

The usual honours course covers three years. The first year is devoted mainly to mathematics, elementary physics, and mechanics, elementary mechanism, and workshop practice. The elements of surveying are taught in the third term. In the second and third years, lectures are given on applied mechanics, theory of structures, heat and heat-engines and electricity; and the student also does laboratory work in these subjects. During the Long Vacation there are no formal lectures, but demonstrations are given in the laboratory, a drawing class is held, and the workshops are open.

A student who has graduated in another university may obtain the B.A. degree at Cambridge by residing for two years and by getting a first class in the engineering tripos, or by submitting a dissertation of sufficient merit describing original research carried on at the engineering laboratories.

The University of Oxford.

The Chair of Engineering Science at Oxford, which is occupied by Prof. C. F. Jenkin, was founded in 1907, and engineering was added to the list of subjects which might be taken in the Final Honours School of Natural Science in 1909, so that the honours B.A. degree is now open to engineering students.

The course of study recommended may be taken in three years, and is intended to be followed by an apprenticeship at some engineering works, or by a pupilage at an engineer's office; but it may be taken after part or the whole of the apprenticeship, if that is preferred. The course includes all the subjects of the final examination, and these are intended to represent the scientific equipment necessary for an engineer. No attempt is made to teach any technical handiwork, or trade, or to give instruction in the practical details of engineering manufactures; such subjects will be learnt during the apprenticeship, as far as they are required. Instruction in the engineering laboratory forms an important part of the course; the work done in the laboratory consists essentially in making measurements—measurements of all the numerical and physical quantities which form the basis of the science; testing of all sorts is included under this heading. Engineering drawing is another important part of the course. Instruction in surveying is given during the Long Vacation. Physics, including electricity and magnetism, is taught in one of the university laboratories, where special courses, as far as they are required, are provided for the engineering students.

Thus students who intend to take up electrical work may take advanced applied electricity and magnetism as a special subject.

All undergraduates are required to pass "Responsions" or an equivalent examination, which may be done before coming into residence; it is usual for engineering students to pass in an "extra subject," and then to take honours in "mathematical moderations" or the "science preliminary," after which no further examination has to be passed till the "Final Honours School" in engineering science, which is usually taken at the end of the third year. Facilities will be given to advanced students and graduates to undertake research work in the engineering laboratories.

No special school training is required beyond a fair knowledge of mathematics, but a sound basis of physics and elementary mechanics is a considerable advantage; without this the student can hardly expect to pass the science preliminary before the end of his first year, whereas with it he may pass at the end of his first term, and thus secure two extra terms for preparation for the final examination.

II.—UNIVERSITIES, COLLEGES, AND TECHNICAL SCHOOLS IN THE PROVINCES

There is, of course, a wide difference between the training given at the various classes of institutions. The large modern universities in most of the principal towns have now electrical engineering departments, at which the student can obtain a thorough theoretical groundwork, not too academical in nature, and precisely that which is required in the education of an engineer, while at the same time he has the opportunity, if he so desires, to broaden his mind by other studies as well. At the larger technical colleges, a sound education in electrical engineering is also given, which will equally enable serious students to aspire ultimately to the higher branches of the profession and industry.

Digitized by Google

Lastly, there are a large number of technical schools and institutes, at most of which the evening classes are the all-important feature, and at which the apprentice and workman may acquire a knowledge of the principles underlying their trade. A large proportion of these schools, however, also give instruction in day classes, by taking the full course of which an education of a similar character may be obtained to that at the technical colleges, and at the same time there are more advanced evening classes for those whose ambition it is to attain to higher positions.

These three classes of institution are not defined by any hard and fast line of demarcation, and in the following list we have, therefore, not endeavoured to classify them, but have simply employed an alphabetical arrangement. The notes with regard to each college and school in the list will in indicate clearly the class of instruction to be obtained there.

We have not included descriptions of the equipment. In practically every case this includes a certain proportion of dynamos, motors, transformers, secondary batteries, &c., in addition to measuring instruments both of the laboratory and commercial class, so that the students can use and see the details of the machinery and plant they learn about, and can also be taught how to carry out practical tests and measurements, and become familiar with electrical appliances and machinery generally. Electrical engineering students in most cases also work in the mechanical and other laboratories, where usually they can study methods of testing steam and gas engines, &c. A thorough groundwork in mechanical engineering forms a part of practically all electrical engineering courses.

Bangor (University of North Wales).

Students at the University are required to reside in registered lodgings. The electrical engineering department is one of the many departments of the University of North Wales, and is under the Professor of Physics, Dr. E. Taylor Jones, and two assistant lecturers and demonstrators, one for physics, and one for electrical engineering. Prof. C. H. Bryan is Professor of Mathematics. The lecture and laboratory course extends for two years, and the classes in other departments, including mathematics and chemistry, are open to the students. The laboratory equipment includes some electrical machinery, but the course is regarded as a preliminary training to be completed by practical work in an electrical engineering works. Fee, £14 14s. per annum.

Belfast (Municipal Technical Institute).

The object of this Institute is to provide instruction in the principles of those arts and sciences which bear directly or indirectly upon the various trades and industries. The classes are suitable for persons engaged during the day who wish to supplement and develop the knowledge and experience gained in the workshop, &c. The full course of electrical engineering is four years, and in the third and fourth year the more advanced branches of the subject are taught, including generator and converter design, &c. A course in electric wiring can be taken by second-year students. There is also a regular three-years' day course intended as a preparatory training for those who aim at filling positions of responsibility. Candidates for admission to this must be not less than fifteen years old, and must pass a simple entrance examination. The fees are low in all cases. Prof. R. Stanley is head of the electrical engineering department, and Prof. J. H. Smith of the mechanical engineering department.

Birmingham.

University of Birmingham.

The B.Sc. degree in engineering can be obtained after a four-years' course; the instruction in mechanical and electrical engineering embraces the same subjects throughout, only in the final year considerably more time is given to the designing and testing of electrical machinery in the latter case. Students are required to pass a matriculation examination in English history and literature, mathematics, a foreign language, experimental mechanics, and one other subject, preferably higher mathematics, and to pass an examination at the end of each year. Certain other examinations in the subjects named, such as the Oxford or Cambridge Senior Local Examination, will be accepted in lieu of the matriculation examination. Advanced students who have matriculated elsewhere are allowed to omit the first year of the course on passing the first intermediate examination. Students not wishing to take the degree are admitted to the courses on passing a shorter examination than the matriculation. In the fourth year the work includes the design of machines, apparatus, and complete installations to definite specifications. Prof. Gisbert Kapp is the Professor of Electrical Engineering, and Prof. F. W. Burstall of Mechanical Engineering. The fees are £34, £50, £50, and £55 respectively for each of the four years, in addition to which there is a membership fee of £1 1s. per annum, and a fee of £2 for each of the above examinations.

Birmingham Municipal Technical School.

Courses in electrical engineering are also held, and laboratory work is conducted at the Birmingham Municipal Technical School at low fees, and complete courses can be taken here by students desirous of obtaining a London University engineering or science degree. There are also afternoon classes, intended partly for apprentices and employees of local firms in electroplating and bronzing, electricity (intermediate), electrical engineering (advanced), and mechanical engineering, and complete evening courses, including special lectures in electrical engineering, electrical measurements, telegraphy, telephony, and instruction in jointing armature winding. Special drawing classes for electrical engineering students are also held. The laboratories include a special electro-chemical laboratory. There is an entrance examination, which all students under eighteen years of age are expected to take. Certificates are awarded by the Board of Education, and also for technological examinations held by the City and Guilds of London Institute, and various prizes and scholarships are obtainable. Dr. W. E. Sumpner is the Principal.

Bradford (City of Bradford Technical College).

Students may enter at the age of 15, and have to pass a simple entrance examination. The ordinary electrical engineering diploma course is three years, but there is a fourth-year course for those who can stay for it. Occasionally students of exceptional attainments are excused the first year. The fourth year's course deals more in detail than that of the third year with the theory, design, and testing of machines, and with central station practice. The head of the department of engineering is Prof. G. F. Charnock, and Mr. W. G. Griffith is lecturer in electrical engineering. The fee is £13 13s. per annum for the full course. Evening classes at low fees are given for persons (over 16 years of age) engaged in the various trades, and special courses covering the work necessary, and the intermediate and final B.Sc., London, examinations have also been arranged. A four-years' evening course in electrical engineering can be taken.

Bristol.

The Merchant Venturers' Technical College has been rebuilt after a fire which occurred in 1906. The equipment of the engineering department has been made very complete, and the faculty of engineering of the new University of Bristol is carried on at the college. Those desiring to take a B.Sc. degree in engineering must commence by passing the matriculation examination (which is similar to that of the London University), or some other accepted as an equivalent to it, and then follows a three-years' course of study, with examinations at the end of the first and final year. A general education in electrical engineering is given, and the students from the college may enter for the competitive examinations for admission to the Engineer-in-Chief's department of the General Post Office, and many students have obtained employment with the National Telephone Co. Students not desiring to take a degree are relieved of the matriculation examination, and can take the three-years' course (preceded, if necessary, by a preliminary course). Prof. David Robertson is head of the electrical engineering department, and, besides the assistant lecturer and demonstrators, there are special lecturers on telegraphy and telephony, and an instructor in electric wiring. Prof. John Munro is the professor of mechanical and mining engineering. The tuition fees for the complete course amount to £26 5s. per annum, but a reduction of £10 10s. is made in the case of students the combined income of whose parents is less than £350. There are also evening classes, the fees for which are lower.

Dublin University.

The School of Engineering, Trinity College, Dublin University, gives a four-years' course in electrical engineering, the fourth year being optional, but recommended. The student is required to be a member of Trinity College and to be subject to its regular discipline, and he has at the same time the opportunity of obtaining the advantages of a general university education. He has first to pass an entrance examination in simple mathematics, English history and composition, modern geography, Latin, and either Greek, French, or German, and a further examination in mathematics, including trigonometry and elementary mechanics. A student will be entitled to obtain a Certificate in Engineering, a Licence in Engineering, a Degree of Bachelor of Engineering, and a Diploma in Electrical Engineering, according to the courses gone through and the examinations passed. Prof. W. E. Thrift is professor of experimental physics; Prof. T. Alexander, professor of civil engineering, is head of the engineering department; Messrs. W. Tatlow and P. S. Sheardown (electrical engineer to the Dublin United

Digitized by Google

Tramways) are lecturers in electrical engineering, and Mr. W. E. Lilly lecturer in mechanical engineering. The fees amount to about £30 per annum, and there is an entrance fee of £15.

Edinburgh.

University of Edinburgh.

Students must pass an entrance examination in English (including set books in literature, history, and geography), mathematics (including trigonometry and algebra to the theory of binomials), dynamics, and either Latin, Greek, French, or German. "Leaving certificates" issued by the Scottish Examination Department may exempt candidates for the whole or part of the examinations. The degree of B.Sc. in engineering is obtainable after a course of 2½ years, but a considerable number of students take 3½ years. Eleven courses of study must be taken, six of which may be taken outside the University. Great stress is laid upon laboratory work. Prof. T. Hudson Beare is head of the engineering department.

Heriot Watt College.

The classes held in the day college are recognised by the University of Edinburgh, and part of the course of instruction in engineering is given at the University. Arrangements with some engineering firms permit students to work as apprentices from March to October in their second year, and to complete their apprenticeship after completion of the college course. Students must pass an entrance examination in English and mathematics, and either experimental science and one language or two languages, but those who have previously passed equivalent examinations may be exempted. The full college course is from three to four years. Prof. F. G. Baily is professor of electrical engineering. Fees from 15 to 20 guineas per year, or for complete training in five or six years, including apprenticeship premium, from £120 to £200. Evening classes are also held at the college.

Glasgow.

University of Glasgow.

In most cases the students work at the University during the winter session from October to March, and spend the remaining six months of the year in works. A candidate for the B.Sc. degree in engineering must attend at the University for not less than three years, taking certain courses of instruction, which he can combine to a certain extent as he chooses, and passing certain prescribed examinations. Certificates of "Proficiency in Engineering Science" are also granted to students after a three years' course with examinations. Students who have obtained the diploma of the Glasgow and West of Scotland Technical College (see below) can obtain the B.Sc. degree in engineering after one year's attendance at the University, taking the necessary courses of study and passing prescribed examinations. Prof. Gray is professor of physics, Prof. Barr of engineering, and Mr. J. S. Nicholson is lecturer in electrical engineering. The fees, including examinations, amount to from £20 to £25 per annum.

The Glasgow and West of Scotland Technical College.

A complete three years' course in electrical engineering is held at the Glasgow and West of Scotland Technical College, which qualifies for a college diploma and associateship in electrical engineering, the total fees for the three years amounting to £35 14s. Evening classes are also held. The professor of electrical engineering is Dr. Magnus Maclean, with whom are several assistants and lecturers. Candidates for the degree of B.Sc. in engineering of Glasgow University who hold the college diploma are admitted to the examinations for the degree after attendance for at least one academical year on prescribed University courses. Entering students must pass a preliminary examination, the standard of which will be raised in 1910 to that of the leaving certificate of the Scottish Education Department, which calls for a thoroughly sound secondary school course continued to the age of 17 or 18.

The University of Leeds.

The University of Leeds, which as the Yorkshire College was at one time a part of the Victoria University, with those of Liverpool and Manchester, but is now an independent organisation, contains an electrical engineering department, presided over by Prof. G. D. Aspinall Parr. In the courses the student is brought into contact, as far as practicable, with the manipulation, uses, and working of electrical apparatus and machinery, but it is considered desirable that students should have some practical experience before taking the University course. The course qualifying for the degree of B.Sc. in electrical engineering covers three years, and can only be entered upon after passing the matriculation examination of the joint board of the Universities of Manchester, Liverpool, Leeds, and Sheffield (which involves one language, but not necessarily either Latin or Greek, and can be taken before leaving school). An intermediate examination is held at the end of the second year and a final examination of a more specialised nature at the end of the third year. Students not entering for a degree can also take the regular three years' course, and in special cases a two years' course. The fee for the full course is about £30 per annum. Research students are admitted to the laboratories. An advance evening course with laboratory work is also given.

Liverpool.

The University of Liverpool.

The University of Liverpool confers the following degrees in Engineering:—Bachelor of Engineering (B.Eng.), Master of Engineering (M.Eng.), and Doctor of Engineering (D.Eng.). The matriculation examination is the same as that mentioned above in the case of the University of Leeds. The course for the B.Eng. degree occupies three years; for the ordinary degree an intermediate and a final examination must be passed, and there is an additional examination for honours. The M.Eng. degree is conferred on Bachelors of three years' standing, either on the passing of a further examination or the presentation of a dissertation upon an engineering subject. The degree of D.Eng. is conferred upon Masters of Engineering of not less than six years' standing from the date of admission to the degree of Bachelor of Engineering, who are adjudged to have distinguished themselves by their original contributions to the science of engineering. Candidates up to the final ordinary degree have a general engineering training. Specialisation in the higher branches of electrical engineering can be done by remaining a fourth year to attend the Honours school or to qualify for the M.Eng. degree. These special courses deal with generator, transformer and motor design; transmission and distribution of electrical energy, including central station practice and design of transmission lines, electrical illumination; and there are also courses for telegraphy and telephony and electric railways. The object of this training is to give the student a thorough knowledge of the main principles of the subject. He has a thorough training both by lecture, laboratory, and class work in all kinds of electrical measurements, and the working of all the important types of electrical machinery and of electric lamps, batteries, &c. The fees for the ordinary courses amount to about £36 per annum. The professor of electrical engineering is Dr. E. W. Marchant, and Mr. J. K. Catterson-Smith lectures on electrical engineering.

Municipal Technical School, Liverpool.

The electrical engineering department of the Central Technical School, Byrom Street, Liverpool, provides a course of work at low fees (in evening classes only), including laboratory work, extending over three years, it being assumed that the students entering the course have had a preparatory training in elementary engineering subjects such as is provided in the two-years' course at the branch technical schools. Students are not admitted to the classes at the Central Technical School unless they are able to pass the entrance examination equivalent to the standard for the completion of the second year of the preparatory course referred to. The special instruction in electrical engineering is based chiefly on the syllabus of the City and Guild's Institute; the instruction comprises both lecture and laboratory work. Students desiring to continue their course are referred to the special evening course of lectures at the Liverpool University. There is a special systematic course of instruction for wiremen. Mr. J. Lloyd Barnes is Lecturer in Electrical Engineering, and Messrs. J. M. Robertson and E. S. Francis, Lecturers on Telegraphy and Telephony respectively.

Manchester.

The University of Manchester.

Engineering subjects may be taken to qualify for the ordinary B.Sc., or honours B.Sc. degrees of the University of Manchester. In the case of the honours degree, there is a regular three-years' course, in which electrical engineering can be included. The matriculation examination is similar to that of the University of Leeds and Liverpool already mentioned, and for the ordinary degree an intermediate examination must be passed as well. A further degree of M.Sc. is conferred on graduates of certain standing, who are required to present a thesis. Students who are not candidates for a degree may also take a three-years' engineering course similar to that for the honour B.Sc. in engineering, and qualify for a certificate in engineering. The subject of electrochemistry is dealt with by the chemical department, and there is a special electrochemical laboratory. The fee for the engineering course is about £30 per session, not including degree and examination fees. Students can reside at certain licensed halls of residence or in registered lodgings. The Professor of Engineering is Dr. J. E. Petavel, F.R.S. Extensive new engineering laboratories have recently been opened.

The Municipal School of Technology.

The Manchester Municipal School of Technology in Sackville Street is connected with the University of Manchester in that day students who have been through the courses there can qualify for Manchester degrees of Bachelor and Master of Technical Science (B.Sc. Tech. and M.Sc. Tech.). The School is under control of a joint Board, and virtually forms the

Digitized by Google

Faculty of Technology of the University. There is a very complete special three-years' course in electrical engineering, one feature of which is that it includes instruction in German. For those not taking the University degree an entrance examination is required instead of the University matriculation, and a certificate of the University in technical science is given. The fees amount to twenty guineas for each complete session. The electrical engineering laboratories are very fully equipped. Mr. J. H. Reynolds is Principal. Students desirous of admission must be not less than sixteen years of age, and must produce a satisfactory reference in respect of conduct and progress from the school previously attended.

Armstrong College, Newcastle-on-Tyne.

The Armstrong College, Newcastle, forms a part of the University of Durham, and students passing a similar matriculation examination to that of the other northern universities or its equivalent, and taking a three- or four-years' course in electrical engineering can qualify for the Durham degree of B.Sc. A similar three-years' course can be taken which qualifies for a college diploma, or a second-class diploma can be obtained after a two-years' course. No preliminary examination is required for the diploma courses. The fees for either degree or diploma course are: First year, £21; second year, £26; and third year, £26. Laboratory fees are charged extra. The head of the electrical engineering department is Prof. W. M. Thornton.

University College, Nottingham.

Special facilities for the study of electrical engineering are afforded at University College, Nottingham. The day courses are intended for boys who have just left school, but more advanced students can join the senior classes. The courses are arranged with regard to the requirements of the London University examinations. Students can combine the first-year engineering course with the London matriculation course; the second-year course is suitable for the intermediate examination in science (engineering), and the third-year course is intended to prepare students for the B.Sc. degrees in engineering of the London University. Students who wish to obtain the general certificate given for the first-year's work must satisfy the professor before entering that they have a fair knowledge of English composition and elementary mathematics, but can be admitted without any examination. Arrangements are made for students to visit and inspect works, &c., during the courses. Certificates are given to students attending the complete course and passing the examinations at the end of each session. The fees are £6 for each of the first three terms, and £3 3s. for the summer term, including all laboratory and workshop charges. Prof. W. Robinson is the head of the engineering department, and Mr. R. A. Sheldon lectures in electrical engineering.

The University of Sheffield.

The full three-years' course in electrical engineering at Sheffield, which includes lectures and classes, experimental work in the laboratories and practical work in the drawing office, workshops, and machine tool shop, qualifies for the degree of Bachelor of Engineering (B.Eng.), but non-degree students are allowed to take the whole or any portion of the course. Those reading for the degree are required to pass the matriculation examination of the joint board of the northern universities, to which we have already referred, and must complete the full course before taking the final degree examination. The fees for the full course are 24 guineas per annum, not including certain small registration and examination fees. A similar course to the degree course qualifies for the Associateship in Engineering, and the evening classes are arranged so that the same Associateship examinations can be taken by evening students. A certain amount of electrical work is also done in other departments at the University. A special course is given for mining students on electricity in mining, and the equipment of the metallurgical department, which includes two Kjellin electric furnaces, gives opportunities for the study of electrometallurgy. The Professor of Engineering is Dr. W. Ripper, and Mr. E. H. Crapper lectures in electrical engineering.

The Technical College, Sunderland.

An important feature of the Technical College, Sunderland, is the arrangements which have been made for the granting every year of a certain number of "Apprentice Studentships," which entitle their holders to pass free of class fees through the three- or four-years' course of study in the day classes of the College prescribed for the diploma of Associate of the College in electrical engineering. The apprentice students attend the College classes during the six winter months, and during the summer months they return to their work as apprentices in the works or drawing office of some firm in the neighbourhood. The time spent at the College is reckoned as part of the apprenticeship, and the rate of advance in wages is the same as if they were continuing in the shops. Candidates for these studentships must be under eighteen years of age, and have served the first two years of their apprenticeship, except in special cases. An entrance examination has to be passed. There are also evening classes in electrical engineering, including telegraphy and telephony, which are arranged to correspond with the examinations of the City and Guilds of London Institute. The Principal of the College is Mr. V. A. Mundella, and Mr. T. C. Baillie is head of the electrical engineering department.

Some notes on the electrical engineering courses at the leading colleges and institutions of technical instruction in London will be given in our next issue.

LOCOMOTIVES FOR THE DETROIT RIVER TUNNEL

THE first of the six locomotives built by the General Electric Co. of America and the American Locomotive Co. (Schenectady) for the Detroit River tunnel, which is said to be the most powerful continuous-current locomotive in the world, has just been taken over, and is described in the *Electric Railway Journal*. The specifications require the hauling of an 1,800-ton train up gradients of 2 per cent. at 10 m.p.h., with two locomotives working on multiple units. The complete locomotive weighs about 90 tons, and is of the articulated four-axle pattern, equipped with four "G.E.-209" motors of about 300 h.p. Its maximum speed is but 35 m.p.h., and hence no pilot wheels are required to relieve the stresses on the rail induced by high speed when rounding curves. The articulated construction is of some interest. The weight is carried on semi-elliptic springs resting on the journal-box saddles, and these are connected together for equalisation in the following way:—The *A* end of the running gear—or what may be called the forward truck—is side equalised, the two springs on each side being connected together through an equaliser beam. This equalises the distribution of weight between the two wheels on one side, giving to this truck a two-point support, and consequently leaving it in a condition of unstable equilibrium as regards tilting stresses—that is, stresses tending to tip the truck forward or backward. The *B* end of the running gear, or what may be called the rear truck of the locomotive, is cross-equalised, the two springs on the rear axle being connected together through an equaliser beam. The other two springs on this truck are independent and are connected directly to the truck frame. This results in a three-point suspension on the rear truck, leaving it in a condition of stable equilibrium, capable of resisting stresses in any direction, whether rolling or tilting. The two trucks are coupled together by a massive hinge, so designed as to enable the rear truck to resist any tilting tendency of the forward truck. This hinge combines the two trucks into a single articulated running gear, having lateral flexibility with vertical rigidity.

The motor equipment consists of four G.E.-209 motors. This is a standard General Electric box-frame, commutating-pole type of motor, and has a rating of approximately 300 h.p. At its one-hour rating the motor will develop a torque of 4,050 lbs. at 1-ft. radius. The gearing between motor and axle has a 4·37 reduction, and the driving wheels are 48 in. in diameter. With this reduction, each motor will develop a tractive effort of 9,000 lbs. at the rail-head, which gives a total tractive effort for the four motors of 36,000 lbs. at 12 m.p.h. The motors have an overload capacity sufficient to slip the driving wheels, and the locomotive can develop at the slipping point of the wheels an instantaneous tractive effort of 50,000 lbs. to 60,000 lbs. The maximum speed of the locomotive, running light upon a level track, is about 35 m.p.h.

There are two gears and pinions per motor, one at either end of the armature shaft. This construction was used on account of the unusually heavy torque and the excessive overloads that the motors will be called upon to carry. In large sizes of motor equipments, with a gear and pinion at only one end of the shaft, it has often been claimed that a large proportion of the wear and breakage of pinions is due to the tilting of the motors under heavy loads, which concentrates the pressure at one end of the tooth.

The motors are designed for forced ventilation. Air is delivered into the motor frames at the end farthest from the commutator, passes between the field coils and around the armature, and finally escapes through suitable discharge openings over the commutator. The blower used for this purpose has a capacity of 2,000 cubic ft. of air per minute at 2¼ in. of water pressure, and is driven by a direct-current series motor. The control system used is the Sprague-General Electric multiple unit type, with two master controllers in the main cab and the contactors in the auxiliary cab. Multiple-unit connections have been supplied, so that three locomotives may be operated in unison, if necessary.

The number of resistance steps in the control circuits is unusually high, affording smooth acceleration, which is very essential under operating conditions such as will exist in the Detroit River tunnel with its steep approaches and sharp changes of grade.

REVIEWS OF BOOKS

Electric Lamps. By Maurice Solomon. 321 pp. 8¼ in. by 5½ in. 112 illustrations. (London: Archibald Constable and Co.) 6s.

THE volumes of the "Westminster" series to which this belongs are intended to appeal to an educated reader, but not to those engaged in the particular industries to which they refer, and their object is to present in a form neither too highly technical nor too "popular," the present state of some industrial application of science. Mr. Solomon has limited himself to electric lamps of forms in commercial use and the principles underlying them without dwelling upon the historical, except when it bears directly on modern practice. His introduction on the principles of artificial illumination might be read with advantage by many, to the improvement of some of the crude and even harmful methods of illumination too often seen, and his second chapter on the production of artificial light, together with that on photometry and methods of testing, are a clear exposition of the more scientific side of the subject, dealing with matters about which, although they are not really complicated, much misconception exists. His point of view on the question of selective emission is open-minded, but he continues: "It may be fairly certainly stated that such differences as may exist play but a small part in the efficiency obtained with different types of lamps in which an incandescent solid forms the source of light, and that it is temperature alone which determines their efficiency, that substance giving the most economical light which is capable of being run continuously at the highest temperature.

A good deal of space is given to the manufacture and properties of the carbon-filament lamp, but it is acknowledged that, beyond detail improvements in methods of manufacture, there have been no radical alterations in the carbon-filament lamp since its invention, with the exception of the "metallised" carbon filament, which perhaps came too late to be appreciated, owing to the introduction of the metal filament lamp. We feel almost inclined to prophesy that if Mr. Solomon adheres rigidly to his scheme of dealing only with lamps in commercial use, that this chapter will have to be omitted in editions in the near future. The Nerst lamp, which is still making a brave fight against the all-conquering metal lamp, is also dealt with at some length, but, of course, the part of the book that will be sought most eagerly is that devoted to the metal filament lamps themselves. A perusal of this shows most strikingly the rapidity of development in this direction. Even in the few months since the book was published much has been done. The 200-volt lamp of reasonable size has made its appearance, and the patented processes under which filaments are manufactured have multiplied. Even at the time the book was written, the Osmium lamp might have been omitted, as it had been practically superseded by the Tungsten lamp under its various names. It is a pity that this chapter is spoilt by the very erroneous comparison of the consumption of Tantalum and Tungsten filaments on page 190, although more correct figures are given in other places. Later chapters in the work deal with arc lamps, and in this section not the least interesting part is that devoted to the manufacturing and testing of arc lamp carbons, a subject on which the author is well qualified to write as the manager of the only carbon works in this country. A few notes follow on the attempts at still more efficient forms of electrical illumination embodied in the mercury vapour and Moore vacuum tube lamps, and the book concludes with an interesting and suggestive chapter comparing the field of usefulness of lamps of different types.

The Calculus and its Applications. By R. G. Blaine. 321 pp. 5 in. by 7¼ in. 79 illustrations. (London: Archibald Constable & Co.) 4s. 6d.

THE sub-title of this book, "A Practical Treatise for Beginners, especially Engineering Students," is hardly justified, for another dozen pages at least are required for an elementary introduction to the subject. The preface contains a somewhat disparaging refererce to "the many students who, nowadays, wish to obtain a working acquaintance with the subject, without, or with very little, aid from a teacher." The author solicits hints from teachers and others. The reviewer is merely an "other person" who has no sympathy with the half measure suggested. Let a book be a mere collection of problems, with the answers, and in some cases the working of the solution, or let it be a true text-book. In the former case it will be suitable for the docile "internal" student, and, in the latter, the "external" free lance may read it at home.

There is much that is excellent in this book. A chapter on "Practical Problems (so-called)" shows that the author is alive to one of the worst faults of the pedagogic mathematician.

Engineering Units of Measurement. By J. Ramsay. 36 pp. 5½ in. by 8½ in. (London: Simpkin, Marshall, Hamilton, Kent and Co.) 1s.

THE title of this little book would almost lead us to expect simply a book of tables of standard symbols, metrical equivalents, &c., such as there are many existing. We find, however, that the author has provided a much more useful work, in which are also collected together in a classified scheme not only units, but definitions and concise statements of the laws governing the physical quantities themselves are given, with the object of imparting a thoroughly clear idea of quantities sometimes liable to be confused. The purely mechanical section is extremely complete and well thought out. Electrical quantities are only treated shortly. The practical units only are dealt with, giving the ohm and ampere in accordance with the resolutions of the International Congress. After the exactitude of these definitions it is a little incongruous to find approximations of the nature of 1,000 watts = 1⅓ h.p. in the definitions of power and work. These are certainly convenient for ordinary calculations, but more distinction should have been made between accurate equivalents and approximations.

Japanese Patents. By H. S. Bickerton Brindley. 57 pp. 5½ ins. by 8½ ins. (London: British Press, Ltd.) 5s.

IN the introduction to this little handbook, Mr. Bickerton Brindley asserts that it is all important that inventors and manufacturers should take immediate steps to protect by patent such of their inventions as are likely to find a sale in Japan, as, apart from trade in Japan itself, the overseas trade of that country is extending rapidly; indeed, he thinks that the time will soon come when Japan will be making a very serious bid for a good share of the China and Manchurian manufactured trade. As a guide to those wishing to take out patents in Japan, Mr. Brindley has prepared the translations of the most important sections of the Japanese law relating to patents, utility devices, trade marks, and designs, of which this handbook is composed. He recommends that the translation from the English and the final preparation of the Japanese specification should be made by a registered agent in Japan, which he himself is, and, indeed, it is necessary that the application for a patent should be made through an agent in Japan. Instructions to be followed by applicants for patents, &c., and the formalities to be observed in connection with certificates of power of attorney, are given, together with translations of the various forms which have to be filled up. A specimen patent specification with an accurate full-size reproduction of a patent drawing, prepared according to the requirements of the Japanese Patent Bureau, concludes this useful little volume. There can be no doubt as to the accuracy of the translations, as Mr. Brindley has long been in practice in Japan as a consulting engineer and patent agent.

The Engineering of Ordnance. By A. Trevor Dawson. 53 pp. 9½ in. by 7 in. 68 illustrations. (London: Percival Marshall and Co.) 2s. 6d.

THIS is a reprint, forming a supplement to the Transactions of the Junior Institution of Engineers, of a "Gustave Canet" lecture delivered by Mr. Dawson in June last. Many features of gun construction are dealt with. Drawings and particulars are given of electric, as well as hydraulic gun mountings, including a description of the Janney "controller," or universal speed gear, and various electrical appliances for fire control.

ELECTRICITY SUPPLY OF LAUNCESTON, TASMANIA

Four Alternative Proposals to Increase the Available Power

A REPORT has been drawn up by Messrs. C. J. David and R. J. Strike, civil and electrical engineers, respectively, to the city of Launceston, Tasmania, on the possible methods of increasing the available electric power for the supply of that city, and an abstract of this report has appeared in the *Australian Mining Standard*. The present supply is obtained from a water-power station on the River South Esk, but this is not large enough to meet the demand, and does not admit of extension without considerable alteration to the hydraulic works.

Four alternative proposals are given in the report. The first consists in constructing a new tunnel from a point higher up the river to a point below where the present station is situated, and erecting there a new station. This would give a working head of 270 ft. and an average flow of 5,000 cubic feet per minute during the dry summer months, giving a summer minimum of nearly 2,000 electrical h.p., and an average output over the whole year of 3,850 h.p. In the summer, with the aid of a new dam, a peak load of 3,200 h.p. could be negotiated. The existing station could be either dismantled or retained for manufacturing purposes, with restrictions as to its use in the summer. The total cost of the proposed new works is estimated at £82,438, made up as follows :—A 20-ft. dam above the tunnel intake, £7,700; hydraulic equipment, including intake, dam, tunnel, concrete race, steel pipes and receiver, and all necessary valves, screens, &c., £55,554; land and buildings, £2,365; electrical equipment, including removal of four 300-kw. generators, exciters, and switchgear from existing station, new turbines for the same, and four new 600-kw. generators, turbines, switchgear, and transmission line, £16,819. If the existing works were left intact, the total cost of the new works would be £87,542. The first instalment of this scheme would cost £75,100, and the report points out that, reckoning interest and sinking fund at 5½ per cent., the annual expenses would be increased by £4,381 at once, and that it would be very difficult to increase the revenue by this amount for some years to come.

As an alternative to the above scheme, the suggestion is made of increasing the capacity of the present station by erecting the 20-ft. dam included in the above scheme, by improving the present tunnel, and by installing an auxiliary heat engine station in the city. A third alternative is to increase the size of the present tunnel, giving a supply from a temporary steam plant while this is being done, and a fourth is to construct a new tunnel parallel to the existing tunnel, and increase the capacity of the present station.

The engineers do not favour any attempt to improve the present tunnel, but suggest that the present station could be used, according to the second scheme, with an auxiliary steam or gas-engine station. As the maximum winter load in eight years' time, including a tramway load, is estimated as not more than 2,300 h.p., and the maximum power of the present station is 1,380, the auxiliary heat-engine plant would have to supply 920 h.p. If steam engines were adopted, the installation of three triple expansion engines direct-coupled to three-phase generators is recommended. The total cost of the whole station would be about £23,500. If gas or oil engines were adopted, the total costs of the stations are estimated at £38,500 and £36,500 respectively, the excess over the steam station being mainly accounted for by an elaborate arrangement whereby the engines drive continuous-current generators, which, in conjunction with a large storage battery, drive motor-generators for delivering the three-phase current to the line. This arrangement is apparently deemed necessary by the engineers to make the supply reliable.

The second alternative consists in hiring a steam plant for six months in the year for two years, during which period the present tunnel would be enlarged so as to carry about three times the quantity of water, and the 20-ft. dam constructed. An addition to the station plant of four 400-h.p. water-turbines and generators would be required, and the total cost of this scheme, including £5,000 for the loaned steam plant, £6,570 for enlarging the tunnel, and £9,200 for other hydraulic work, is estimated at £38,800. This scheme provides for a maximum output of 3,450 electrical h.p., which is greater than the estimated demand 20 years hence, and, with the hydraulic work completed, no auxiliary heat-engine plant would be required.

As a third alternative scheme, the construction of a new 6-ft. tunnel parallel to the first, and the erection of dams, with a corresponding extension to the power plant in the existing station, is proposed. The power obtained would be equal in amount to that available under the third scheme. The estimated cost of this last proposition would be as follows :—Two dams, £9,196; new tunnel and hydraulic work, £18,900; building extension, steel pipes, four 400-h.p. turbines and generators, £18,034; giving a total of £46,130.

The figures in the above estimates do not cover the cost of the mains and other apparatus necessary to the development of the distribution system.

THE WEST STANLEY COLLIERY DISASTER

Inspectors' Report

THE report of Messrs. R. Redmayne and R. D. Bain, H.M. Inspectors of Mines, on the explosion at the West Stanley Colliery, which occurred in February last, and which resulted in the death of 168 men, has just been issued. A large amount of evidence was given at the inquiry, a report of which was given in ELECTRICAL ENGINEERING, April 8th, 1909, page 324, but this was so conflicting that the inspectors have been unable to arrive at any definite conclusions respecting either the point of origin or the cause of the explosion, except that it was due to the ignition of coal-dust. Whether the ignition was due to an electrical cause or not, they cannot say, but they add that on the assumption that the explosion originated in the Busty Seam (as was thought to be the case by the jury after the inquiry) they are of the opinion that electricity is a more likely first cause than any of the alternative suggestions.

Mr. R. Nelson, H.M. Electrical Inspector of Mines, in a special appendix to the report, describes the electrical equipment of the colliery, and makes some observations on the probable cause of the explosion. He points out that there is strong evidence against any possibility of the switch, fuse, or motor in the Busty Seam having caused the explosion, but considers that external arcing of the cables consequent upon mechanical damage by falling coal is a more probable reason. He concludes :—"Though electricity cannot be acquitted of suspicion in the absence of other positive cause, there is no direct evidence against it, any more than against any one of the dozen safety lamps which the evidence showed to be still unrecovered from the pit. A review of the evidence suggests one or two general considerations :—(1) The use of cables with earthed metallic outer sheathing wherever possible; (2) attention to mechanical details of gas-tight apparatus with the idea of ensuring that the apparatus shall be gas- and dust-tight in fact; (3) the proper protection of cables during shot-firing operations; (4) the use of oil-break switches with overload trip coils, wherever possible, in substitution for or in series with ordinary fuses; (5) the use of apparatus without exposed live metal terminals; (6) the importance of frequent inspection and cleaning where exposed live metal terminals are in use.

Colliery Fatality.—A miner named J. M'Mahon, employed in the Auchingeich Colliery, Chryston, came in contact with a live wire while engaged in carrying out some repairs last week, and was killed instantly by electric shock.

Wireless Telegraphy.—The Argentine Government has resolved to establish wireless stations for a service between Buenos Aires and Ushuaia at a cost of $75,000 gold. It is hoped that the stations will be working by May, 1910.

A new wireless station will shortly be opened at Cherbourg. This station may be used by the public and by vessels fitted with proper apparatus. The charges for vessels communicating with this station (exclusive of the rate charged on board) will be 80 centimes a word.

Digitized by Google

LOCAL NOTES

ABERDEEN: *Universal Penny Fares.*—The Council have decided to institute a system of penny fares only on their tramways, the stages being from the centre of the town to any of the termini. It is estimated that on last year's traffic there will be a loss of £4,000 under this scheme, but as the idea is to stimulate traffic, the Council hope that the extra traffic under the new arrangement will counterbalance this loss.

Electrical Apparatus on Hire.—The Council recently purchased £50 worth of electrical apparatus for hiring out, but this has been taken up so quickly that it has been found necessary to purchase further apparatus to the value of £150.

AMBLE (Northumberland): *Electric Lighting.* The ratepayers are to ballot upon whether a scheme of electric lighting shall be adopted.

AUSTRALIA: *Sydney: Tube Railways.*—The Royal Commission appointed last year to inquire into the general question of improvements in the City of Sydney, recommend the construction of tube railways under the harbour in order to dispense with the present system of ferries, which is regarded as dangerous to the general shipping. The Commission further recommend that a central authority should be appointed to initiate and carry out street improvements which extend beyond the boundaries of any one municipality, and that the State should bear its due proportion of the cost of improvements of a general character.

Sydney: Electrical Employers' Association.—A society called the Electrical Employers' Association of New South Wales has been formed. This will have the same relation to the employers as the Electrical Employees' Union has to the workpeople.

BRADFORD: *Tramway Accounts.*—The total revenue from the Corporation tramways during the year to March 31st, 1909, amounted to £244,235, a net increase of £1,086 on last year's figure. Traffic receipts, however, were £331 less than in the previous twelve months. Parcels traffic is mainly responsible for the increase in total receipts. Total expenditure, including interest and sinking fund, was £170,196, compared with £167,994 last year, an increase of £2,202, thus giving a net decrease in gross profit of £1,116. After meeting capital charges, &c., there is a balance of £15,518, against £17,258 last year, and this has been transferred to reserve and renewals fund, which now stands at £44,461. In accordance with the Board of Trade requirements to equip several cars with speed indicators, a sample speed indicator has been obtained. This is to be installed on the car used for training drivers. New designs have been made for the dual gauge axle Leeds-Bradford cars. The revenue per car mile was 10·905d., and the expenditure 7·598d. The number of passengers carried was 47,660,011, compared with 47,839,569 in the previous year.

CHESTERFIELD: *Tramway Accounts.*—The accounts of the Corporation tramway department for the year to March 31st last show a gross profit of £4,901, the revenue amounting to £12,157, and the expenses to £7,256. After meeting interest and sinking fund charges, there is a balance of £600, out of which provision has to be made for renewals and depreciation. The number of passengers carried was 2,481,321, the revenue being 9·46d. per car mile, and the expenditure 5·935d.

CHINA: *Electric Lighting.*—A British Consular report states that a project for lighting Amoy by electricity has been mooted for some time, but has not yet assumed any concrete form owing to want of capital.

Telephones.—During the year 1908, a telephone service was established in Amoy City, and it is proposed to link up the system with that of Kulangsu by a submarine cable across the harbour.

COSTA RICA: *Electric Supply.*—The Costa Rica Electric Light and Traction Co. has extended its tram line in San José, from the Pacific station to Rio Torres, about one mile, and is building a further extension to Guadalupe (2½ miles). According to a British Consular report, the company has also acquired rights for a 5,000 h.p. water-driven power station at El Brazil, and has commenced work.

DEVONPORT: *Summonses re Tramway Service.*—The local magistrates have now given their decision in regard to the summonses taken out by the Corporation against the Devonport & District Tramways Co. for ceasing to run a service of cars upon certain leased lines. We reported the arguments on p. 704 of our issue for August 5th. The total number of summonses was 155, divided into two sets, one numbering 83 for the non-running of a service of trams required by the Corporation in the public interest, and the second numbering 71, for non-compliance with an agreement to run workmen's cars. The magistrates found against the company, and inflicted a fine of £5 and costs for the first of the 83 summonses, and in the remainder 2s. 6d. and costs for each day. With regard to the second set of summonses, the company was fined £2 and costs for the first day, and 1s. and costs for each of the subsequent 70 days. The company subsequently applied for leave to appeal, alleging that the decision was wrong in law.

DUBLIN: *Electric Lighting Loan.*—The Corporation have taken up a loan with the Royal Liver Friendly Society of Liverpool, for £18,650 at 3¼ per cent., for electric lighting purposes.

DUNFERMLINE: *Tramways.*—The Council have recommended that bracket arms attached to buildings should be adopted by the promoters of the West Fife tramways for carrying the trolley wires instead of standards.

GLASGOW: *Decreased Tramway Receipts.*—Since the beginning of the financial year on June 1st, 39,634,205 passengers have been carried on the Corporation tramways, in comparison with 40,557,054 in the corresponding period of last year, while the receipts have been £162,016 10s.—a decrease of £4,566 8s.

Electricity Works' Accounts.—The accounts of the Electricity Department to May 31st, show gross revenue amounting to £245,675, and expenditure to £104,902. Interest on loans absorbs £54,748, and sinking fund £36,308, leaving a balance on the year's working of £49,715. Depreciation amounts to £55,259, making a deficit on the year's operations of £5,544, and this has been met out of the reserve fund, which now amounts to £19,281. The reduction in the charges for current granted last year, the introduction and extensive use of metallic filament lamps, and the general trade depression, have caused a decreased income of £7,729, which, however, is more than counterbalanced by an all-round decrease in the working expenditure of £10,415. The balance on the year's working is £140,771, as compared with £138,085. The deficit is due to the increased contribution to the sinking fund of £4,000, and to the increase in depreciation to the extent of £3,108, as compared with the previous year. Capital expenditure during the year amounted to £168,378, and the total capital expenditure on May 31st was £1,800,202.

GOVAN: *Electricity Accounts.*—The report of the Borough Electrical Engineer upon the working of the electricity department for the year to May 15th last has been issued. The total revenue amounted to £17,090, and expenditure to £9,148. The balance has been applied to meeting sinking fund charges and interest; the sum of £528 has been transferred to renewals reserve account, and small amounts applied as depreciation of office furnishings, arc lamps, &c. The total number of units sold was 2,356,367, the total maximum supply demanded being 1,485 kw. The number of motors let out on hire is now equal to 760 h.p., and the number of arc lamps is 79. It has not been found, however, that many new consumers desire arc lamps, and this is attributed partly to bad trade and partly to the use of metal filament lamps, which in many cases are being installed instead of small arc lamps. The number of units sold for lighting shows a slight decrease from the previous year, due to the increased use of metal filament lamps and decreased consumption of works on short time. The number of units sold for power shows an increase of 17·2 per cent. The revenue from private lighting is lower than last year, which is accounted for by the fewer number of units sold, and also because a good number of consumers have reduced their maximum demand by installing metal filament lamps, and at the same time have burned longer hours, thus reducing the average price per unit. Several other consumers, who were on the maximum demand system, and who on that system were paying a higher average price than 3½d. per unit, decided to be charged on the optional flat rate system of 3½d. per unit. The income from power supply, whilst larger than last year, was at a lower price per unit, due to the increasing number of consumers getting the benefit of the lower prices on the sliding scale. Total costs amount to 1·585d., including capital charges.

GRAVESEND: *I.M.E.A. Expenses.*—Although the Council had already sanctioned the expenditure, a councillor at the last meeting moved that the expenses of the Borough Electrical Engineer and Chairman of the Electricity Committee at the Convention of the Incorporated Municipal Electrical Association in June should be disallowed on the ground that the ratepayers reaped no benefit. The motion found no seconder, however.

HULL: *Workhouse Lighting.*—The Guardians have been negotiating with the Corporation for better terms for a standby supply. Mr. H. Bell, the Borough Electrical Engineer, has quoted £4 per annum per kw. of maximum demand, plus 0·5d. per unit. The Guardians regard this as unreasonable, and suggest that a standing charge of £5 or £10 per annum should be charged. The matter is to be further discussed.

JAPAN: *Large Water-power Scheme.*—It is reported that a company of Japanese and British capitalists is being formed to establish an immense hydro-electric power industry in Japan. This company will be incorporated under the Canadian law.

KILREA (Ireland): *Electric Lighting.*—A proposal to form a company for the purpose of erecting an electric supply works is under consideration.

PERTH: *Tramway Deficit.*—During the past year there was a loss of £1,562 on the tramways, and it has been decided to levy a rate of 2⅛d. in the £ to meet this, and to reduce the suspense account.

PORTSMOUTH: *Tramway Profits.*—At the last meeting of

Digitized by Google

the Corporation, several speakers objected to the granting of £2,000 from the tramway profits to relief of rates. The Tramways Committee's recommendation, however, was carried.

RHYL: *Diesel Oil-engine Set.*—We announced last week that the Council desired tenders for a Diesel oil-engine generating set. Mr. E. H. Wright, the Council's Electrical Engineer, has prepared a report dealing with the best method of providing necessary extensions, and states that he decided to recommend the installation of a Diesel engine on account of its extreme economy in fuel and the small attendance it requires. After referring to a number of other towns where these engines are at work and have effected considerable economies in works costs, Mr. Wright points out that the Diesel Oil Engine Co. are prepared to guarantee that the works cost at full load shall not exceed 0·6d. per unit generated, as compared with the present works cost at Rhyl of 1½d. per unit. By the outlay of £3,530 decided upon by the Council it is calculated that a reduction of £360 per annum in the cost of fuel will be effected, besides a saving of £100 on repairs and maintenance, £30 in oil, water, and stores, and £120 on labour. This gives a total saving of £610 a year, from which, however, £254 for capital charges must be deducted, assuming that the required loan of £3,530 is granted for 20 years.

SHEFFIELD: *Tramways Accounts.*—The accounts of the Corporation tramway department for the year ended March 31st last show a total revenue of £288,860, and a total expenditure of £180,606. After meeting capital charges there is a net profit of £36,635, and after placing £21,454 to renewals fund and meeting other charges, the balance of £15,000 is transferred to relief of rates. The passengers carried numbered 76,356,031, compared with 77,568,686 in the previous year. The revenue per car mile was 9·512d., against 10·049d., and the working expenses 6·32d. per car mile, against 6·505d. per car mile.

SOUTH AFRICA: *Oudtshoorn: Electric Lighting.*—It is stated in *Commercial Intelligence* that the Oudtshoorn Electric Lighting Co. has transferred its agreement with the local Town Council to the General Electric Co., of London. Lighting plant will be installed without delay.

SOUTHEND: *Light Railways.*—The Light Railway Commissioners have submitted to the Board of Trade for confirmation the Southend & Colchester Light Railways (Amendment) Order, which revives the powers granted, and extends the time limited by the Southend & Colchester Light Railways Orders, 1904 and 1905, for the compulsory purchase of land and the construction of works. Objections should be lodged with the Board of Trade by September 10th. The Southend-on-Sea Light Railways (Revival and Extension of Time) Order has also been submitted to the Board of Trade for confirmation. This order revives the powers granted by the Southend-on-Sea & District Light Railways (Extension) Order, 1901, and extends the periods limited by the Order for the compulsory purchase of lands and the completion of works.

URUGUAY: *State Telephone Scheme.*—A British Consular report states that last year a Special Committee was appointed to report upon the question of instituting a Government or municipal telephone service; they have recommended the institution of a national telephone service with underground lines, in accordance with plans drawn up by a British engineer, in place of the present overhead wires system, and a project of law dealing with this question, which is, however, beset with certain legal and equitable difficulties in connection with the existing telephone companies, has been submitted to the Chambers by the Government. The cost of the proposed work, calculated at £212,766, will probably be met by a loan of £319,149 at 5 per cent., and 1 per cent. redemption. It is not expected that there will be the slightest difficulty in raising this loan, as the Post Office surplus revenue has for several years averaged £19,149 per year, and last year it amounted to £24,664. This revenue will only be under contribution during the time of construction as the telephone service, once it is established, will, it is anticipated, after deducting 50 per cent. for expenses, produce an income of £21,276 per year.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BARNSLEY.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £3,000 for electric lighting purposes, mainly for cable extensions.

LEEDS.—The Electric Lighting Committee require tenders for the supply of cables for one, two, or three years, at the option of the Corporation. The value of the cable required by the Corporation in recent years has been from £8,000 to £10,000 per annum. Particulars from the Borough Electrical Engineer (fee one guinea, returnable), and tenders to the Town Clerk by September 7th.

PLYMOUTH.—The Corporation invite tenders by September 2nd for a turbo-alternator. Particulars from the Borough Electrical Engineer.

WISHAW (N.B.).—The Corporation require a three-wire direct-current switchboard for their Craigneuk sub-station. Particulars from the Electrical Engineer, and tenders to the Town Clerk by November 30th.

Miscellaneous

DUBLIN.—The Corporation require tenders by August 31st for an electrically driven water-sprinkling car. Particulars from the secretary to the Cleansing Department, 3 Cork Hill, Dublin.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON: E.C.—Warehouse building (£4,120). E.C. Architect, W. L. Dowton, City Bank Chambers, Bedford Row, W.C.

S.E.—Assembly hall and additions to schools, Bermondsey, S.E. (£746). Architect, J. Moir Kennard, 13 Railway Approach, London Bridge, S.E.

S.W.—Alterations, Vine Street Police Station, W. (£4,000). Surveyor, J. Dixon Butler, New Scotland Yard, S.W.

PROVINCES.

ACTON.—Extensions, Cottage Hospital, W. (£980). Builder, George Bollom, 1a Essex Road, Acton, W.

BARROW.—Skating rink, Abbey Road. Secretary, Barrow Rink Co.

BELFAST.—Warehouse for Messrs. Adams. Builder, J. Hogg, Jury Street, Belfast.

BLACKBURN.—Mission hall, King Street (£2,500). Architect, F. J. Parkinson, 9 Richmond Terrace, Blackburn.

Church. Architects, Gradwell & Son, Victoria Street, Blackburn.

BURNLEY.—The Guardians have decided to obtain tenders for the electrical work required for the new Nurses' Home and alterations to the Infirmary.

CHICHESTER.—School (£8,650). Architect, Haydon P. Roberts, Education Offices, Horsham.

CROYDON.—Skating rink. Architects, Berney & Son, 104 George Street, Croydon.

DARTMOUTH.—Swimming baths. Borough Surveyor.

GARSTON.—Bank (£3,000). Architect, Woolfall Eccles, Castle Street, Liverpool.

GATESHEAD.—Church Hall (£3,000). Architect, R. Wylie, Gateshead.

HOYLAKE.—Hospital. Builder, J. Merritt, Birkenhead.

KEIGHLEY.—Confectionery Works (£2,000). Architects, J. Haggas & Sons, Keighley.

LIVERPOOL.—Residence (£2,200). Architect, H. L. Beckwith, Castle Street, Liverpool.

Printing works (£4,500). Architects, J. & A. Burroughs, Vernon Street, Liverpool.

SKIPTON.—New banking premises (£3,000). Architect, J. W. Broughton, 19 High Street, Skipton.

TAUNTON.—Post Office. Builders, Cowlin & Sons, Bristol.

TUNBRIDGE WELLS.—Church. Rev. A. D. Rowe, Wilkins Road, Tunbridge Wells.

WOLVERHAMPTON.—School (£12,750). Architects, Fleeming & Son, Wolverhampton.

Extensions, School (£3,750). Architect, as above.

TENDERS RECEIVED AND ACCEPTED

ACTON.—The tender of the St. Helens Cable Co., Ltd., has been accepted for the supply of lead-covered paper insulated cables for the ensuing year.

DAWSON CITY.—Messrs. J. Booth & Sons, of Bolton, have secured the contract for the constructional steel-work required for the new electric power station of the Northern Light, Power, & Coal Co., which will supply the local mining district with electricity for lighting and power purposes. It is stated that the order was secured in face of keen competition with American and German firms, and that the scale was finally turned in favour of the British tender by the operation of the Canadian preferential tariff on British goods.

GRAVESEND.—A short while ago the Council decided, on the advice of their electrical engineer, to invite tenders for an automatic stoker. These were duly received, and one at £215 was recommended for acceptance. At the last meeting of the

Digitized by Google

Council, however, a motion that this expenditure was unnecessary, and that the plant was working quite satisfactorily at present, was carried by nine votes to eight.

LONDON: *Greenwich.*—The Guardians have accepted the tender of Messrs. Medway & Co., Deptford, for the installation of two electric lifts at the East Greenwich Infirmary.

NEWPORT (MON.).—The Council have accepted the following tenders: Liverpool Electric Cable Co., 2,500 yards of small cable, £65 6s. 9d., less 2½ per cent.; General Electric Co., lamp fittings, £1 2s. 6d. per set.

PAIGNTON.—Twelve of the existing street gas lamps are to be converted for three 50-c.p. Osram lamps at £2 10s. per lamp by the Paignton Electric Light & Power Co.

PONTYPRIDD.—The following tenders have been received for a 500-kw. engine:—Browett, Lindley & Co., Ltd., J. H. Holmes & Co., Bruce, Peebles & Co., Ltd., James Howden & Co., Ltd., Brush Electrical Engineering Co., Ltd., Lancashire Dynamo & Motor Co., Ltd., British Electric Plant Co., Ltd., Siemens Brothers Dynamo Works, Ltd., Rees Roturbo Manufacturing Co., Ltd., Phœnix Dynamo Manufacturing Co., Ltd., Dick, Kerr & Co., Ltd., General Electric Co., Ltd., British Thomson-Houston Co., Ltd., Electric Construction Co., Ltd., British Westinghouse Co., Ltd.

COMPANIES' MEETINGS AND REPORTS

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—The report and accounts given in our last issue were adopted at the meeting on Thursday. The chairman, Sir George Gibb, stated that the issue of capital to the contractors was now complete. During the past two years the increase in the passengers carried had been no less than 60½ per cent., and it was gratifying to notice that the largest increase was in respect of passengers paying the higher fares.

BAKER STREET & WATERLOO RAILWAY CO.—At the half-yearly meeting on Thursday, the report and accounts given in our last issue were adopted. Sir George Gibb, who presided, called attention to the satisfactory position, the receipts having gone up and the expenses down, with the result that they had been able to double the small dividend paid in 1908. The number of passengers carried had increased by 11 per cent. After meeting the full 4 per cent. dividend on the preference shares, 1½ per cent. on the ordinary shares, and a further 1½ per cent. on the ordinary shares except those held by the Underground Co., the sum of £3,105 was carried forward. With regard to the Paddington extension referred to in the report, the directors had no hesitation in recommending the abandonment of this, as they had, after careful consideration, come to the conclusion that large railway termini, such as Paddington, did not yield large traffics to a line such as theirs.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—At the meeting on Thursday, the report and accounts given in our last issue were adopted. Sir George Gibb, who presided, pointed out that the increase in the gross revenue amounted to 18·3 per cent., and was the largest percentage of increase shown by any London traffic-carrying company.

TYNESIDE TRAMWAYS & TRAMROADS CO.—The accounts for the half-year to June 30th show a surplus of receipts over expenses of £3,746, which, with the balance brought forward from last half year, makes a total available of £4,388 10s. 10d., and after deducting interest on debentures, loans, &c., there remains an available balance of £3,246. The directors propose a dividend on the preference shares of 5 per cent. per annum (less income tax), and a dividend on the ordinary shares of 1 per cent. per annum (less income tax). It is also proposed to place to the credit of reserve for renewals, depreciation, and other contingencies, the sum of £900, and for the reduction of registration and formation expenses, £330. The amount carried forward is then £773. The amount available for distribution shows an increase of £790 as compared with the corresponding period of last year. The traffic receipts are £747 better than they were last year, though the depression in the trade of the district continues. At the meeting last week, the report and accounts were adopted.

METROPOLITAN DISTRICT RAILWAY CO.—At the half-yearly meeting last week, the report and accounts given in our last issue were adopted. Sir George Gibb, chairman of the company, presided, and pointed out that the passenger receipts for the June half-year were a record, being higher by £10,900 than the highest previous receipts in any half-year, viz., the December half of 1908. Now that the undertaking was in a more satisfactory position, the directors were discussing a scheme for capitalising the arrears of dividend on the 4 per cent. guaranteed stock, which at present amounted to about 20 per cent. on the nominal value of this stock, which was £1,250,000.

LIVERPOOL OVERHEAD RAILWAY CO.—At the half-yearly meeting on Tuesday, the report and accounts given in our last issue were adopted. Sir William Forwood, the Chairman of the company, who presided, said that there had been a shrinkage in receipts during the past half-year of £2,486, mainly due to trade depression, but there had been a saving of £3,138 in working expenditure through the introduction of a less expensive train service. This had given every satisfaction, which proved that they had not sacrificed efficiency for economy.

ELECTRIC SUPPLY CO. OF VICTORIA.—The accounts of this company for the year to March 31st, 1909, show a credit balance of £7,760, to which has to be added the £8,582 brought forward, making a total of £16,342, after meeting debenture and other interest. Preference dividend to March 31st, 1908, absorbs £7,800, and debenture stock redemption £3,962, leaving £4,581.

APPOINTMENTS AND PERSONAL NOTES

An interesting little ceremony took place recently at the electricity works of the Bradford Corporation, when Mr. Chas. W. Salt, chief assistant to Mr. Thomas Roles, City Electrical Engineer and Manager, was presented by the staff and employees with a handsome brass-mounted oak clock and a calabash pipe on the occasion of his marriage with Miss Ida Potts, of Bradford. Mr. Roles, who made the presentation on behalf of the subscribers, spoke of the high esteem in which Mr. Salt was held in the department, and several members of the staff cordially endorsed his remarks. Mr. Salt suitably responded.

Mr. T. Medcalf, General Manager of the Swindon Corporation tramways, was married to Miss Alice Grey, daughter of Alderman J. M. Grey, J.P., of Bolton, on Thursday.

Mr. Frank Stuart Milne, who some time ago left the Newcastle-upon-Tyne Electric Supply Co., Ltd., to take up an important appointment in the Argentine in connection with the Electrical Department of the State Railways, has, in view of the rapid commercial expansion of the Republic, commenced business in Buenos Aires as commercial engineer and agent for British railway, mechanical, and electrical engineering firms. Associated with him as British engineer and secretary is Mr. J. A. Seager, and any firms desiring representation should communicate with the latter gentleman at his office, Emerson Chambers, Newcastle-on-Tyne.

Mr. Harold Dickinson, engineer and manager of the Leeds Corporation electricity undertaking, has been presented with a grandfather clock, silver tea and coffee service, and other articles by the electricity works staff on the occasion of his recent marriage.

Mr. R. Cleaver, a director of the Northampton Electric Light & Power Co., who died on June 14th, left estate valued at £38,364, with net personality *nil*.

Mr. E. H. Westwood, of 369 Collins Street, Melbourne, has been elected secretary of the Electrical Association of Victoria.

The Llandilo Urban District Council require an Electrical Engineer to take charge of the municipal electrical undertaking under the supervision of the Consulting Engineer. Application to the Clerk, stating salary, by August 31st.

An electric wiring instructor is required at the Northampton Institute, Clerkenwell, London.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 15s. to £61 5s. per ton (last week, £60 to £60 10s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of Messrs. Thomas Parker, Ltd. (in voluntary liquidation for the purpose of reconstruction), will be held at the office of the liquidator, Lich Gate, Wolverhampton, on September 17th, at 2.30 p.m., for the purpose of hearing the liquidator's account of the winding-up.

Mr. A. Riding, 15 Cockspur Street, has been appointed receiver and manager to the London Electrobus, Ltd., under powers contained in a trust deed dated December 7th, 1908.

Mr. D. Gibson, 4 Kingsmead Road, Birkenhead, has ceased to act as receiver and manager of the Bogota Telephone Co., Ltd.

The last day of receiving proofs in the bankruptcy of L. W. de Grave, Electrical Engineer, 19 Queen Street, Derby, is September 1st. The trustee is Mr. F. Stone, 47 Full Street, Derby.

Herbert Shuttleworth, Electrical Engineer, Cross Court, Briggate, Leeds, has been adjudicated bankrupt. The first meeting of creditors will be held on August 25th at the Official Receiver's Office, 24 Bond Street, Leeds, and the public examination will be held on September 14th at the County Court House, Albion Place, Leeds, at 11 a.m.

MESSRS. A. P. LUNDBERG & SONS.—This firm notify us that Mr. H. Jackson is no longer representing them.

CANADIAN IMPORT DUTIES.—The Canadian Customs Department have decided to admit British commutator bars of copper, cut to form, for electrical apparatus under a preferential import duty of 15 per cent. *ad val.* The general tariff is 27½ per cent. *ad val.*

METAL FILAMENT LAMPS.—The Metallic Seamless Tube Co., Ltd., of Birmingham, inform us that they are now in a position to supply from stock 25-c.p. high-voltage metallic filament lamps.

SHIP CARBONS, LTD.—We are informed that Mr. James Veit has been appointed Secretary, and Mr. F. B. Pell, Sales Manager, to this Company.

PARLIAMENTARY INTELLIGENCE

GLASGOW CORPORATION TRAMWAYS.—This Bill, which came before a Select Committee of the House of Commons on Thursday, was ordered to be reported for third reading. As stated in a previous issue, a number of railway companies opposed the tramway clauses, which sought to make it clear that the Corporation tramways undertaking is part of the Common Good, into which all their profits had hitherto been paid. It is generally accepted by the ratepayers that this is so, but the Scottish Office have expressed a doubt about it, hence the clause in the present Bill to define the position. The committee passed the proposal.

PROGRESS OF ELECTRICAL BILLS.—The Torquay and Paignton Tramways Bill was read a third time in the House of Commons on Friday.

Electric Lighting Provisional Orders Confirmation Bill (No. 1) and Tramway Orders Confirmation Bill were read a third time and passed in the House of Commons on Monday.

ROYAL ASSENT.—The following received Royal Assent on Monday:—Electric Lighting Order Confirmation (No. 2) Act, 1909; Dudley Corporation Act, 1909; York Town and Blackwater Gas (Electric Lighting, &c.) Act, 1909; Preston, Chorley, and Horwich Tramways Act, 1909; County of Durham Electric Power Supply Act, 1909; Liverpool Corporation Act, 1909; Southport and Lytham Tramroad (Abandonment) Act, 1909; Wallasey Tramways and Improvements Act, 1909; North-East London Railway Act, 1909; Folkestone, Sandgate, and Hythe Tramways Act, 1909; Manchester Corporation Act, 1909; Oxford and District Tramways Act, 1909; South-Western and Isle of Wight Junction Railway Act, 1909; Gateshead and District Tramways Act, 1909; Central London Railway Act, 1909; Holywood Tramways Act, 1909; London County Council (Tramways and Improvements) Act, 1909; West Kent Electric Power Act, 1909; Greenock Corporation Act, 1909; Heywood Corporation Act, 1909; Watford Urban District Council Act, 1909; Oldham Corporation Act, 1909; Torquay and Paignton Tramways Act, 1909; Shrewsbury Corporation Act, 1909.

THE NATIONAL TELEPHONE CO.—In answer to questions in the House of Commons on Tuesday, the Postmaster-General stated that he was aware the National Telephone Co. had discharged a certain number of construction hands during the present year owing to a slight diminution of the amount of new work and orders. There was no evidence, however, that the company were causing inconvenience to subscribers by failure to carry out alterations and repairs to plant. The condition of the plant would be taken into account in the settlement in December, 1911, and the company had, therefore, a direct interest in keeping it up to date. He had just concluded an arrangement with the company for the continuance of certain new work, and he was in communication with them as to arrangements for establishing new exchanges in the districts served by their system. He was assured that the company were not refusing to connect up new subscribers.

NEW COMPANIES

ALFRED WISEMAN.—Registered on July 30th, with a capital of £15,000 in £1 shares, to take over the business of an iron and general metal founder, engineer, electrical and other tramway, equipment and weighing apparatus specialist, manufacturer, &c., carried on by A. Wiseman at Venus Works and Globe Works, Glover Street, Birmingham, as "Alfred Wiseman," the "Electric Tramway Equipment Co.," "S. C. Parkes & Co.," and "F. and J. Allen." The subscribers are:—A. Wiseman, 89 Glover Street, Birmingham, engineer; J. W. Harris, The Laburnums, Bilston, engineer. Registered by Alfred H. Atkins, Ltd., 27-8 Fetter Lane, E.C.

LAING WHARTON.—Registered on August 12th, with a capital of £3,000 in 2,900 preference shares of £1 each, and 2,000 ordinary shares of 1s. each., to carry on the business of electricians, mechanical engineers, makers of and dealers in electricity, suppliers of light, heat, and power, &c. Registered by H. J. Moore, 2 Gresham Buildings, Basinghall Street, E.C.

GENERAL ACCESSORIES CO.—Registered on August 9th, with a capital of £3,000 in £1 shares (1,580 6 per cent. preference, 920 5 per cent. preference, and 500 ordinary), to carry on the business of manufacturers of and dealers in electrical goods of all kinds, general merchants, warehousemen, factors, and agents, &c., and to adopt an agreement with E. C. Friend. Registered office, 148-150 Curtain Road, E.C.

GEARY ADAMS & CO.—Registered on August 9th, with a capital of £3,000, to adopt an agreement with F. C. Geary, and to carry on the business of electrical installation and general engineers and agents, &c. Registered by Alfred H. Atkins, Ltd., 27-28 Fetter Lane, E.C.

VIVO VIBRATOR CO.—Registered on August 11th, with a capital of £1,000 in 5s. shares, to adopt an agreement with G. L. Hogan, J. W. Walker, jun., and Sir Edward Sullivan, Bart., and to carry on business relating to massage treatment, also as chemists, druggists, manufacturers of electrical and other scientific apparatus, &c. Registered office, 329 High Holborn, W.C.

DYNAMIC ELECTRICAL CO.—Registered on August 6th, with a capital of £100,000, to acquire all or any of the undertakings, businesses, properties, and assets of the Dynamic Syndicate, Ltd., the Dynamic (French) Syndicate, Ltd., and the Mitcham Electric Fan Co., Ltd., to adopt agreements with the said companies and the liquidators thereof, and to carry on the business of electricians, engineers, makers and manufacturers of and dealers in electric and other motors, fans, dynamos, tools, induction coils, and other machinery and electrical apparatus, &c.

MISCELLANEOUS CITY NOTES

CHLORIDE ELECTRICAL STORAGE CO.—A dividend of 10 per cent. is recommended for the past year, placing £5,000 to reserve and carrying £14,200 forward.

CROSSLEY BROS.—An interim dividend of 2 per cent. has been declared.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The transfer books and register of members of this company will be closed from the 18th to the 31st August, 1909 (both days inclusive), for the preparation of warrants for interim dividends payable the 31st inst., on the 7 per cent. cumulative first preference shares and 6 per cent. cumulative second preference shares, for the half-year ended 30th June, 1909.

NORTHAMPTON ELECTRIC LIGHT & POWER CO.—An interim dividend of 4½ per cent. per annum (less tax) has been declared on the "B" ordinary shares for the June half-year.

CALCUTTA ELECTRIC SUPPLY CORPORATION.—At a meeting on Monday, a resolution to amend the Articles of Association by adding the words "allowing a commission on the placing of shares to be paid not to exceed 10 per cent.," was confirmed.

TANTALUM LAMPS IN RUSSIA

As an outcome of the popularity of the "satisfied consumer" poster used by Messrs. Siemens Brothers Dynamo Works for advertising tantalum lamps, the design has been translated into Russian, German, Spanish, and Portuguese, in order that the same idea may be brought before the public mind of

these countries. It will be readily understood, however, that for different countries an alteration in the design is necessary to bring it into line with the prevailing types of the country represented. We reproduce here the Russian version, and it will be noticed that the design is similar to the English one, but is made to appeal to the Russian idea of "satisfaction."

Tramways & Telephone Exchanges.—We announced a short while ago that the Board of Trade had appointed Mr. G. L. Macfarlane, K.C., as arbitrator in the case between the Postmaster-General and the Tramways and Light Railways Association on the question whether the cost of fuses and heat coils for the protection of telephone exchange apparatus from the effects of accidental contact with overhead tramway conductors should be borne by the tramway authority or the Post Office. The case selected was that under the Wemyss Tramway Order. The arbitration, we learn from the August circular of the Tramways and Light Railways Association, took place on July 23rd, when Sir Robert Hunter and Major W. A. J. O'Meara represented the Postmaster-General, and Mr. Sydney Morse and Mr. Stephen Sellon represented the Association. The arbitrator's award has not yet been given.

MULTIPLE-SPEED INDUCTION MOTORS

IN a Paper read before the American Institute of Electrical Engineers at their summer meeting in June last, Messrs. H. G. Reist and H. Maxwell discuss the various methods of obtaining more than one efficient speed for three- and two-phase induction motors. For work where variable speed is required, the authors state, a motor with collector rings is used, the speed variation being produced by varying the amount of resistance inserted in the secondary circuit. Such a motor is wasteful of power whenever resistance is used, and the speed varies greatly with the load when much reduction in speed is required. It sometimes happens that two or three speeds will be satisfactory. For such conditions, multiple-speed motors, in which the different synchronous speeds are produced by changing the number of poles, can be used. Each of these speeds is fixed if no resistance is used in the secondary circuit, so that a change in load will produce only a very slight variation in speed, and the motor will operate efficiently at each speed. Secondary resistance may be used to vary the speed below each of the synchronous speeds.

A change in the number of poles may be produced by :—(*a*) changing the number of poles by re-grouping the coils, (*b*) by the use of independent electric circuits, or (*c*) by means of separate magnetic and electric circuits.

The selection and design of the motor is affected principally by the number of speeds required, the ratio of the desired speeds, and the ratio of the maximum outputs at the different speeds.

The first type has probably been used more extensively than any other, due to its economical use of material, all of which is active at all speeds. A disadvantage is the large number of leads which must be brought out, and the complicated switching apparatus needed. For any ratio of two speeds other than 2 : 1, the ordinary three-phase winding requires 33 leads. A two-phase winding requires 16 leads. If more than two speeds are desired, the number of leads will be greatly increased. In this form of motor the same coils are used for the different arrangements of poles, the relative pitch of the winding depending on the number of poles. Since the economy of a winding rapidly decreases when the pitch of its coil is less than one-half, it is disadvantageous to build motors of this type having a greater ratio of speed than 2 : 1. On account of the large number of leads required, it is not practicable to use this type of winding on the rotors of induction motors, except with a ratio of 2 : 1 speed, with which arrangement only six collector rings are required. With all other speed-ratios the number of collector rings would become prohibitive, so for these motors a squirrel-cage rotor is generally used.

There are a number of different methods that may be used in connecting the windings, the selection in any case depending on the relative maximum outputs required at the two speeds. The connection for which the material is worked to the best advantage, has a half-speed rating of from 60 per cent. to 70 per cent. of full-speed rating. The following table gives several connections that may be used, with the approximate relative outputs. The third combination is the one generally used, as it best suits the average conditions of a load which requires constant torque at the two speeds; that is, when the output of the motor is proportional to the speed.

	Speed.	Connection.	Approximate maximum output.
(1)	100	2-circuit Delta	100
	50	Y-Delta	11
(2)	100	2-circuit Y	100
	50	1 ,, Y	22
(3)	100	2 ,, Y	100
	50	1 ,, Delta	66
(4)	100	1 ,, Delta	100
	50	2 ,, Y	117
(5)	100	1 ,, Y	100
	50	2 ,, Y	350
(6)	100	Y-Delta	100
	50	2-circuit Delta	700

These values will vary slightly with the ratio of the reactance to the resistance and also with the ratio of the coil-end to the slot part of the reactance leakage. It will be seen that there is a wide range of maximum torque from a little over 10 per cent. for the half-speed connection, to about seven times that of the full-speed connection. These various combinations are often valuable in unusual cases to maintain a good power-factor and efficiency at the desired loads. In most of these combinations the material is not worked to equal advantage at both speeds.

The second type of motor, having independent windings, has three leads for each speed in the stator for a three-phase and four for a two-phase motor. The slots are usually made large enough to contain all the windings. It is usually impracticable, however, to use more than two windings. The relative maximum outputs are independent of each other, but to work the magnetic material to advantage they should be approximately proportional to the speed. The motors of this type have to be built large for their output in order to allow space for the increased amount of copper and insulation. The space occupied by insulation becomes excessive on high-voltage motors so that this type is applicable chiefly to low-voltage windings. It is possible in this form of motor to utilise one or more of the windings mentioned in the table, thus increasing the possible number of speeds.

The concatenated or cascade motor is the only motor of the third type in general use. The rotors are mounted on the same shaft, the secondary of the first motor being directly connected to the primary of the second. If the two motors have different numbers of poles, there will be four synchronous speeds, two for the motors independently and two for the combination. If the speed corresponding to the difference in the number of poles is higher than the synchronous speed of the first motor, the set will not accelerate by itself to this speed; and although there might be ways of accelerating to this speed, the switching devices will be complicated so that from a practical standpoint this combination is not generally considered. By using in concatenation two of the half-speed motors mentioned in the table, the number of speed combinations is very large, and the number of leads and switching of the electric circuits, while complicated, may be warranted in some cases. If, for instance, we take a 4-8 pole and a 6-12-pole motor, we can obtain combinations to give motors having speeds equivalent to every possible number of poles from 4 to 20, except 18. The ratio of speed of the two motors is limited by the necessity of changing the poles of each motor, two at a time. A further limitation is the centrifugal stress in the larger motor at high speeds. If the individual motors have the same synchronous speed and can be run in multiple at the high speed, the ratio of the maximum output of the high speed to the low speed is about 4 : 1. If the load requires this ratio of work with the different speeds, the material in the motor is worked to the best advantage. The two conditions—of having a load as desired in the foregoing, and having speeds with ratio of 2 : 1—rarely exist, so in general the material cannot be economically used in concatenated motors. The ratio of the outputs mentioned is usually unfavourable, since in general the output required at the lower speed is more than one-quarter that required at the higher speed. There are some classes of work, however, such as the driving of blowers, where approximately this load-ratio may exist.

On account of the large variation in output at the two speeds, the concatenated motors generally use material at the high speed to a very great disadvantage, so that such motors are usually large and expensive for the work to be done. The most favourable condition for the use of the concatenated motor is when the various speeds required are close together. In such a case the two motors would be very different in size and the large motor would be used for the highest speed; for example, if the large motor had 16 poles and the small one had 4, speeds corresponding to 12, 16, and 20 poles could be obtained. Another disadvantage of the concatenated motor is its low power-factor. This is inherently low, even at the highest speed, owing to the fact that both motors give a poor power-factor because they are underloaded. The maximum output of a motor is inversely proportional to its impedance at a given frequency and voltage, so that if the two single motors have equal impedance, the maximum output of the concatenated couple is approximately one-half the maximum output of one motor alone, and its magnetising current is approximately twice that of one motor—hence its inherent low power-factor in concatenation.

As a guide in the selection of the best type for given conditions, the authors have drawn up the following conclusions :—

(1) For two speeds having a ratio of 2 : 1, use motor type (*a*).

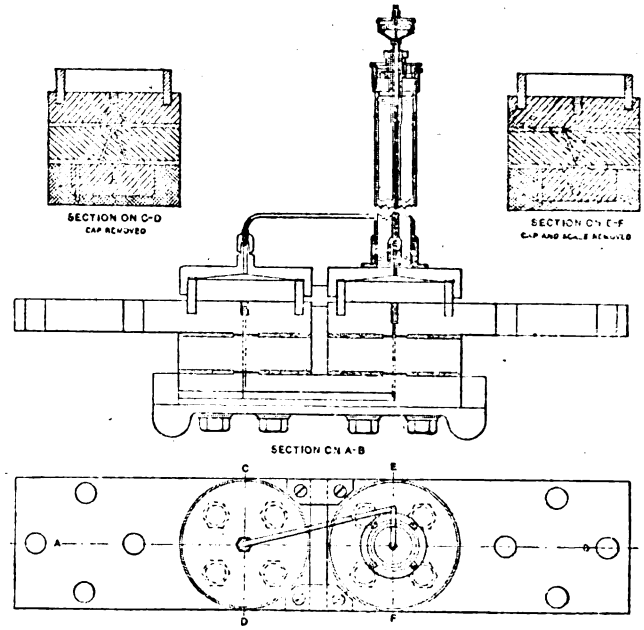
(2) For two speeds having other ratios than 2 : 1, use motor type (*b*), except when the winding and insulation require too much space.

(3) When three speeds are required, two having a ratio of 2 : 1, the other being intermediate, type (*b*) may be used with one winding connected as in (*a*).

Digitized by Google

(4) If four speeds are necessary, one speed being one-half of the highest speed, and the lowest speed one-half of the next highest speed, type (*b*) may be used, with each winding such as is used in type (*a*).

(5) Use type (*c*) concatenated motors, when two or more speeds close together are required.



(6) Use concatenated motors when polar windings on the rotor are necessary with more than two speeds, or if the two speeds differ from 2 : 1.

(1) Use concatenated motors for high-voltage machines except when type (*a*) can be used.

In the discussion which followed the reading of the Paper, reported in the *Electrical World*, Mr. H. C. Specht, Pittsburgh, pointed out that for the various schemes of connections the number of leads is generally dependent upon the number of poles and the type of winding. The maximum output is dependent on the limited density in the copper and iron, and the stresses in the mechanical parts. If the synchronous speed of the second motor is higher than that of the differential concatenation, then the second motor may be connected to the line instead of to the first motor. In the case where neither one of the two motors has a lower synchronous speed than that of the differential concatenation, the speed for the latter cannot be obtained without auxiliary means. The individual motors of a cascade set can be designed for greater width and smaller diameter, thus keeping the peripheral speed lower than would be the case for a single motor for the same speeds. Mr. A. M. Dudley, Swissvale, Pa., suggested that another method of getting multi-speed service is by internal concatenation, putting a two-speed winding on the stator member and also on the rotor. The idle primary is short-circuited and the speed depends upon the number of poles. Dr. C. P. Steinmetz said that there is not much, if any, gain in concatenation or cascade connection compared with changing the poles. The difficulty is to avoid too many poles and hence too large a motor. If one doubles the number of poles to get half the speed, the motor constant is thereby made inferior. In any case, the motor has to be designed better than for high speeds. In concatenation each motor always keeps the same number of poles. One motor only reacts on the supply circuit, and it carries the exciting current of the other motor. The electrical constants of a concatenated couple are inferior, and the characteristics are the same as those of a motor which changes its number of poles. The latter is superior mechanically and from the point of view of manufacturing. Concatenation may be used in railway service. The reactance of the second motor upon the first cannot be overlooked, however.

A NEW AMMETER FOR HEAVY CURRENTS

THE American technical journals describe a somewhat novel form of ammeter for heavy currents, which has been developed in America by the Leeds & Northrup Co. The apparatus is based upon the mutual forces between conductors, or parts of a conductor, carrying current such as would cause a number of free parallel flexible wires carrying current to cluster together, or a liquid conductor to heap itself up in the centre. In the instrument, two vessels of mercury are provided connected by a U-shaped channel through the part main copper conductor, which also takes a U-shaped course. The conductor is so built up in sections with ring-shaped insulators between them, leaving flat circular spaces to be filled by the mercury. These spaces are connected by poles in appropriate directions also for the reception of the mercury. In one arm the action of the current is to make the mercury tend to flow towards the centre of each circular pool, and rise in the outwardly sloping channels which connect the centre of each circular pool of mercury with the outside of that next above it. In this manner, as the connecting pipes are sloped the reverse way in the two arms of the U, the mercury is caused to rise in one chamber and fall in the other, and an indication of coloured water in a tube magnifies the movement. The arrangement is made clear in the illustration. Referring to the cross-sections on *EF* and *CD*, the current, for instance, enters through the upper copper leaf. To get to the next copper leaf of the cell it must pass through the mercury-filled space within the ivory ring (shown dotted). In passing through the disc of mercury it causes the mercury to tend to flow away from the edges and "bank up" at the centre. The force causing this action is exactly the same force that causes solid conductors, carrying current, to tend to attract each other. This attraction toward the centre causes mercury to flow through two diagonal tubes, which tubes extend from the circumference of the disc of mercury to the centre reservoir of mercury. Thus a force is set up which tends to make the mercury flow through tubes and discs of sections *CD* and *EF* and through the connecting tube in the base of the instrument from *CD* to *EF*. In the meter in question there are four points at which the force is exerted, two being in section *EF* and two in *CD*. This force causes mercury to flow until it is just balanced by the force due to the difference in hydrostatic head between the levels of the liquids in the two sides. The ammeter consumes about 1 watt per inch of scale reading, regardless of the amount of current to which 1 in. of scale corresponds. The scale is found to

PLAN AND SECTIONS OF MERCURY HEAVY-CURRENT AMMETER.

follow a square law, and an accuracy within 0·1 per cent. is claimed for continuous current or alternating current of any usual frequency. The instrument is particularly intended for standardising ammeter shunts and current transformers.

The calibration of the instrument is dependent only upon the number and diameter of the discs or cells, the density of the liquid which serves as an indicator and the force of gravity. The liquid is not exposed to evaporation and, due to the fact that the instrument involves only hydrostatic heads, the effect of variations in the diameter of the index tube is eliminated, as is also the possibility of error due to "drainage effects." Within wide limits the calibration is also independent of temperature changes.

Telegraph Traffic and Movements of Cable Ships.—We have to announce the stoppage of communication with Swakopmund in German South-West Africa.—A cable runs from Capetown to Mossamedes, and a branch from that cable connects Swakopmund with the world's telegraphic system. This part became damaged on the 11th inst. From the 13th, however, telegrams could once more be accepted up to Walfisch Bay, subject to delay.—Direct communication between Saigon and Bangkok was restored on the 12th inst., while the line between Rome and Constantinople ceased working on the 14th inst.—On the latter date the cables between Dakar and Conakry, and Trinidad and Demerara, were restored to working order.—The line between Bagdad and Bassorah broke on the 14th inst., and some derangement of the telegraph system has taken place in Japan owing to the earthquake.—We also learn that the cable between Corfu and Trieste ceased working on the 16th inst.—The repairing steamer *Amiral Caubet*, belonging to the Compagnie Française des Cables Télégraphiques, arrived back at Halifax, N.S., after repairing the New York—Cape Cod section of this company.—The cable steamers *Mackay-Bennett* and *Colonia*, the former owned by the Commercial Cable, and the latter by the Telegraph Construction & Maintenance Co., are still engaged on the diversion of the former company's cables to Newfoundland. Some delay to the work has been caused by fog and ice, but the two vessels are to meet at Halifax, N.S., about the present time.—The *Colonia* has been engaged on the New York—St. Johns section, while the *Mackay-Bennett* has been joining the main section off Flemish Cap to the cable laid from there to Newfoundland.—The New York end is landed on Manhattan Beach, near Coney Island. An iceberg caused damage to the main section, necessitating a repair.—The cable between New York and Guantanamo still continues interrupted.—The cable steamer *Relay*, after prolonged operations, abandoned the repair, and the cable steamer *Cambria*, of the Telegraph Construction Co., was chartered to mend the cable. She arrived at New York on the 30th ult., and although she immediately proceeded to the scene of operations, no news of the cable being repaired has yet been received.—The break is in 2,500 fathoms of water, so that some difficulty may be experienced.

THE PECKHAM PENDULUM AND RADIAL TRAMCAR TRUCKS

THE Peckham Truck Co. (Queen Anne's Chambers, S.W.) have sent us some particulars of the Peckham patent pendulum method of truck suspension for tramcar and other trucks, giving a lateral flexibility and freedom for which great advantages are claimed.

This gear as constructed for tramway single trucks consists of an inverted U-shaped link, suspended from a seating in the top of the axle box and flexibly connected to a horizontal bar located underneath the axle box. This horizontal bar is provided at each end with spiral springs, upon which the truck frame is supported. These spiral supporting springs are located 1 ft. 3 in. each side of centre of the axle, increasing the spring support of the side frames (effective wheel base) 2 ft. 6 in.

The action of this gear permits the carriage or truck that it suspends from the axle boxes to pendulate independently of the wheels and axles, the latter being free to follow the rails and adjust themselves to the various conditions of the track. This they do instantaneously and without imparting to the motors, truck, and car body the shocks and side blows they would receive if suspended from the axle boxes by the ordinary rigid gears. When applied to high-speed bogie trucks the swing bolster universally used can be dispensed with, as the pendulum gears serve the same purpose more efficiently.

The same principle can be applied to railway passenger coaches and goods wagons, as well as to a variety of designs of tramcar trucks, including maximum traction trucks. Mr. H. M. Sayers has reported very favourably with regard to a truck on this principle, which has been in use on a car of the West Ham Corporation Tramways, and considers that not only is the riding of the car much improved, but rail corrugation is rendered less likely of occurrence, and the power consumption is considerably reduced on curves as compared with a rigid truck.

The Peckham radial gear is an improvement upon the pendulating gear, and consists in the method of connecting the swing link of the gear with the horizontal spring supporting bar underneath the axle box. Instead of securing the swing link directly to the spring supporting bar, the swing link is connected flexibly to a housing or box that surrounds three sides of the spring supporting bar. This housing is provided with a series of cold rolled steel rollers upon which the horizontal spring bar (that supports the truck frames) is supported. When the wheels and axles radiate on curves, the rollers permit the housing to move in either direction as far as the radius of the curve requires, the jaws of the pedestals of the truck frame being made sufficiently wide to allow for the radiation of the wheels and axles. To prevent the housing from binding against the spring supporting bar when the wheels and axles radiate, the seating for the swing link in the top of the axle box is made separate from the axle box and so that it will swivel, permitting the swing link to remain parallel with the spring plank.

These features, according to a report of Mr. H. M. Sayers, enable the wheels to follow a curving track with a minimum of side thrust, and without shock, whilst the necessary guiding forces are applied to the main truck and car body by each pair of wheels almost directly in line with the wheel flanges, and act about the central pivotal point. This results in a gradual relative movement of trucks and car body at the ends of curves and at changes of curvature. The slung roller bearings oppose the minimum of resistance to the radiating movement when entering curves, and to the straightening movement on leaving them; whilst there is a positive straightening couple tending to prevent radiation on straight tracks. The end extensions of the side frames and the semi-elliptic and spiral car body supporting springs are made sufficiently strong to support the entire weight of the overhang of the car body and prevent teetering, while the pendulating movement of the suspension links of the gear prevent shocks and side motions to the car body.

Colliery Accident.—Two workmen, O. Davies and D. Thomas, employed in the Cribbur Fawr Colliery, Kenfig Hill, Cornwall, received fatal shocks by catching hold of an electric cable on their way down the mine on Thursday last.

Recording Telephone Messages.—A device for recording telephone messages on a phonograph "record" so that they can be reproduced afterwards at will is announced from Milan. The designer, S. Pasquale, a cashier of the Agricultural Bank at Taranto, has named the instrument the "Telephonograph."

Conductivity of Metals under Stress. Some experiments are described in *Elektrotechnik und Maschinenbau* by Dr. J. Sahulka, which were made in order to determine whether the conductivity of metal bars or wires were effected by putting them under stress, as it had occurred to him that if this were the case, the resistance of members of bridges, towers, &c., could be taken as a guide as to their state of stress. It was found, however, after experimenting with iron and aluminium wires, that no difference in the resistance appeared until the elastic limit was reached, when an increase, corresponding exactly to that calculated from the diminished section and increased length of wire due to stretching, was noticed.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

CRANE MOTORS AND CONTROLLERS.—Messrs. Dick, Kerr & Co., Ltd., have just issued a new edition of their catalogue of crane motors and controllers. A number of excellent illustrations are given of the specially designed series of crane motors, with or without their well-known brake, in the form of an electromagnetically operated cone clutch. These motors range from 1·5 to about 150 h.p., and standard outputs and speeds are given at the quarter-hour, half-hour, and hour ratings. Photographs of cranes of a variety of patterns, fitted with these motors, are included. Full particulars are also given of the firm's substantial patterns of metallic shield blow-out controllers, specially designed for the arduous conditions of crane work.

GENERATORS AND MOTORS.—New lists from the Oerlikon Co. (Oswaldestre House, Norfolk Street, Strand) deal with standard patterns of continuous-current motors and generators for small outputs, and small single-, two- and three-phase asynchronous motors.

POWER CHARACTERISTICS OF TUNGSTEN FILAMENTS

AN article in the *Electrical World* by Dr. C. P. Steinmetz describes an experimental investigation into the manner in which the power consumption of tungsten filament lamps increases with increase of voltage.

In pursuit of an extended investigation on the radiation law of the tungsten filament, a series of tests had been made with special care on a number of modern tungsten lamps, extending over a wide range of candle-powers. Taking the readings very quickly, by experts especially trained in photometric work, it was possible to reach ten times the rated candle-power of the lamps, without any appreciable impairment or change of the filament or blackening of the globes, as evidenced by the lamp showing its original candle-power and efficiency after the test. Analysing the relation between the power consumption and the impressed voltage, the interesting result was found that the power consumption varies proportional to the 1·6 power of the voltage; that is, follows a law analogous to that of the hysteresis loss in iron in an alternating magnetic field.

The following table gives the observed values of candle-power, impressed voltage, and current of one of these lamps, a 32-c.p. 40-watt lamp. The fourth column gives the watts. The values of this column can be expressed by the equation,

$$w = 0{\cdot}0235\, e^{1{\cdot}6}$$

with an error in no case reaching 1 per cent.

CP.	Volts.	Amps.	Watts.
2	49·6	0·247	12·25
4	59·6	0·274	16·33
8	70·6	0·302	21·35
12	79·0	0·324	25·60
16	85·3	0·339	28·91
20	90·4	0·350	31·64
24	95·7	0·361	34·55
28	100·5	0·371	37·29
32	103·3	0·380	39·26
36	106·6	0·389	41·47
40	110·9	0·398	44·14
44	113·3	0·401	45·42
48	115·6	0·407	47·05
64	126·6	0·429	54·31
96	142·9	0·460	65·73
128	157	0·489	76·77
192	180	0·529	95·24
256	196	0·556	109·00
288	206·5	0·571	117·9
320	212	0·580	122·9

In the tungsten lamp, the law of the 1·6 power is not only an empirical law, but can rationally be derived as a theoretical conclusion from the temperature law, of metallic resistance,

$$r = a\ T,$$

and the normal radiation law,

$$R = b\ T^4,$$

where T = absolute temperature and R = total radiation power.

Electric Traction in Hungary.—According to the *Financial News*, the Hungarian Minister of the Interior has commissioned the firm of Ganz & Co. to construct an electric railway between the city of Pressburg in Hungary and the Austrian frontier. It is hoped that the line will be ready at the end of next year.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 12th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

17,705/03. **Shade Holder for Incandescent Lamps.** W. A. G. Hill. The carrier is composed of two metal rings, the lower of which has slots in the inner periphery, so that it can be slipped over the lamp cap. The lower ring rests on the shoulder of the lamp cap and presses the upper ring, to which it is attached by one or more springs, against the shade, so as to hold it firmly against the collar on the lamp holder. A single spiral spring surrounding the holder, or two small springs on either side, can be used. The shade comes off when the lamp is taken out. Two claims, five figures.

19,589/08. **Circuit-breaker.** British Thomson-Houston Co., Ltd. (*General Electric Co., U.S.A.*) In this circuit-breaker, the series solenoid is mounted on the arm, and is connected in series between the two fixed contacts of the circuit-breaker when the arm is moved into the closed position. The switch is set by adjusting the position of a movable core in the solenoid. Six claims, six figures.

19,765/08. **Shade Carrier for Incandescent Lamps.** J. Nelson, and Drake & Gorham, Ltd. Outside the barrel of the lamp holder is placed a tube with bayonet slots, which engage with projections on the lamp holder barrel. The lower end of the tube is turned up, and supports a spiral spring which presses the lamp shade up against the collar on the lamp holder. The lamp can be taken out without the shade coming off. Two claims, four figures.

20,268/08. **Circuit-breaker.** Siemens Bros. Dynamo Works, Ltd. (*Siemens-Schuckertwerke Ges.*). This is a switch for automatically breaking the connection between two separately fed sections of a traction conductor as soon as a fault develops in either, and for automatically re-connecting the two sections directly the fault is removed. When the circuit-breaker operates, it simultaneously closes a resetting switch, which causes the breaker to be closed again directly both sections are at the normal pressure. Five claims, three figures.

21,004/08. **Storage Battery Plates.** H. J. Haddan (*Nya Ackumulator Aktiebolaget Jungner*). Graphite plates for accumulators in which an alkaline electrolyte is used are made by heating coal or anthracite with silicic acid to a high temperature in the electric furnace. The graphite produced is very porous, can be sawn into thin plates and worked mechanically, and is indifferent to electrolysis. Methods of producing plates with active masses of nickel and iron respectively are described in the specification. One claim.

26,967/08 and 8,570/09. **Time Relays.** D. Timar and R. Ziegler. These two specifications describe time relays for attaching to circuit-breakers to cause them to operate an interval of time after the overload inversely proportional to the value of excess current. In the first, a device comprising an electromagnet and a vessel containing mercury, which, when inverted, causes contacts to be bridged by the mercury on the principal of the sand-glass, is employed, and in the second, a hollow vessel with a hole in it is plunged into mercury, the latter rising through the hole and closing the tripping-coil circuit. Four claims, seven figures.

Opposition to Grant of Patents

22,647/06. **Igniter for Miners' Safety Lamps.** J. C. Bowie and J. H. Phelps. This patent has been granted, in spite of opposition, and covers a special construction of an air-tight receptacle in which the safety lamp to be ignited is placed, and which contains a hand-driven magneto, a condenser, and a device to prevent the turning of the magneto when the receptacle is open.

20,223/07. **Manufacture of Metal Filaments.** "Z" Electric Lamp Syndicate, Ltd. (*H. Zerning*). The opposition to the grant of a patent on this application has been withdrawn. The patented process, as described in Electrical Engineering of December 10th, 1908, Vol. IV., p. 772, consists in making a paste of a hydrogenous compound of the metal (tungsten hydride) with a binding agent of castor oil, amylacetate, and nitrocellulose. The interior of the vessel in which the squirted filaments are heated is lined with a paste of zirconium hydride and amylacetate.

786/08. **Tramcar Life-guard.** W. Timbrell and C. E. Gabriel. In spite of opposition, the grant of a patent on this application has been allowed. The specification, which describes a life-guard in which the guard itself can work without causing any movement of the resetting handle, was abstracted in Electrical Engineering, April 1st, 1909, page 311.

Revocation of Patent Applied for

2,122/08. **Insulating Material.** W. Claypoole. Application has been made for the revocation of this patent under Section 26 of the Patents Act, the applicant having failed to enter opposition before the grant. The patent covers a process of manufacturing a substitute for ebonite. This consists in heating a mixture of carbolic acid, formalin, and caustic soda to a certain temperature, and then pouring the resultant liquid into moulds. When hard and polished, the moulded pieces look like light grey porcelain. Other similar compositions are described.

Application for Restoration of Lapsed Patent

24,170/04. **Boiler Cleaning.** A. R. Raymer. Application has been made for the restoration of this patent, which relates to a method of cleaning boilers while under steam pressure. The patent expired in Nov., 1908, owing to the non-payment of the renewal fee. Notice of opposition should be given before Oct. 5th, 1909.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: MacGahan [Manufacture of conductors] 23,007/08; Diesser [Impregnating varnishes] 11,166/09.

Dynamos, Motors, and Transformers: Siemens Bros. Dynamo Works (*Siemens-Schuckertwerke Ges.*) [Speed regulation of motors] 18,017/08; Pollet [Electrical driving gear] 22,377/08; Fraser and Tudor Accumulator Co. [Brush-gear] 23,709/08.

Electric Ignition: Deniéport, 18,311/08; Mattonet [Indicator for multi-cylinder engine] 3,403/09.

Electrometallurgy and Electrochemistry: Compagnie Française de L'Ozone [Purification of liquids by ozone] 15,854/08; Frank and Caro [Extraction of nitrogen from combustion gases] 16,963/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Reduction of oxides] 5,821/09; Gröndal Kjellin Co., and Härdén [Induction furnaces] 8,194/09.

Incandescent Lamps: Cooper [Packing lamps] 17,973/08.

Instruments and Meters: Hookham, 15,802/08; Hardingham (*Hartmann & Braun Akt.-Ges.*) [A.-C. magnets for resonance apparatus] 2,016/09.

Switchgear, Fuses, and Fittings: Sandycroft Foundry Co. and Dutton [Liquid motor-starters] 18,623/08; Falk [Lamp-shade holder] 22,964/08; Frauenlob [Lamp shades or globes] 27,523/08.

Telephony and Telegraphy: Colwill and Horswell [Telephone call-box] 16,755/08; Kingsbury (*Western Electric Co., U.S.A.*) [Telephone exchange systems] 17,209/08; Dommerque [Three-wire telephone systems] 18,038/08; Burney and Brinkmann [Intercommunication telephone systems] 25,446/08; Marconi's Wireless Telegraph Co. and Pound [Measurement of decrement of oscillations] 185/09; Johannsen [Telephone exchange switchboard] 3,539/09; Bellini and Tosi [Directive wireless telegraphy] 4,801/09; Eisenstein [Wireless telegraphy] 5,578/09; Vyle [Polarised Morse-sounders and ink-writers] 8,533/09.

Traction: Lambert [Sanding apparatus] 19,475/08; List and Atkinson [Point-operating mechanism] 19,572/08; Griffin [Point-operating mechanism] 27,142/08; Thomas and Harries [Operating points from vehicles] 6,062/09.

Miscellaneous: Siemens Bros. & Co. (*Siemens & Halske A.-G.*) [Röntgen-ray apparatus] 4,252/09; Justice (*Soc. Anon. Electricité Electromécanique*) [Friction couplings for motors driving machine tools] 6,850/09; Allgemeine Elektricitäts Ges. [Cranes and lifts] 8,456/09; Darling [Temperature measuring apparatus] 11,187/09.

The following Specifications are open to Inspection at the Patent Office for Acceptance, but are not yet published for sale.

Dynamos, &c.: Allgemeine Elektricitäts Ges. [Regulation of machines] 17,199/09.

Incandescent Lamps: Canello [Attaching filaments] 15,210/09.

Miscellaneous: Steinert and Stein [Electromagnetic separator] 17,490/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, &c.: P. C. Hewitt [Vapour rectifier] 8,297/04.

Electrometallurgy and Electrochemistry: A. Neuburger and A. Minet [Electric arc furnace] 9,468/04.

Incandescent Lamps: Improved Electric Glow Lamp Co. and A. Barnes [Silvering lamp bulbs] 9,977/98.

Traction: F. H. Daniels [Hollow wire-rope rail-bonds] 15,189/99; J. C. Fell (*H. E. Haddock*) [Rail sanding gear] 9,499/05.

Miscellaneous: O. Kammerer [Electric crane gear] 7,997/00.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

On Wednesday of last week a high-tension wire supplying current to the village of Olginate, Lombardy, broke and fell on to a low-tension wire of the village lighting system, with the result that the wiring in all the houses was raised to the full line pressure of 3,000 volts. Ten persons in houses supplied with electricity were killed, and twenty-nine seriously burnt. (Page 752.)

An Aberdeen correspondent, who sent us particulars of the advantages gained by substituting electric motors for a gas engine, now gives us some further figures with regard to the economies obtained. (Page 753.)

The electric passenger hoist, which conveys tourists up and down between the level of the Wetterhorn Hotel and a point 1,380 feet higher up this famous mountain is an entirely new departure in passenger railways. The cars are hung from four-wheel trucks, which run on two cables supported one above the other. There are two such sets of cables, and the two cars running on them are connected together by two hoisting cables, which pass round electrically-driven winding sheaves in the upper station. Automatic brakes on the trucks grip the suspension cables in case of a breakage of either hoisting cable, and an elaborate system of brakes and safety devices is provided for the winding gear. (Page 753.)

A new pattern of porcelain fuse-carrier, with an attachment to give an indication of the blowing of the fuse, has been introduced. Simplex Conduits, Ltd., the firm manufacturing this novelty, has recently installed a large extruding press in their works for the manufacture of fuse-wire. (Page 757.)

An electrically-worked railway signal has recently been introduced in which the motor is driven either from a central battery at the signal cabin or by a local battery at the post, controlled by a relay. It can be readily applied to any existing post, and only a few dry cells are required, the motor taking very little energy, and the holding-off current being practically negligible. (Page 757.)

Two Papers by Messrs. E. Friedlander and E. W. Yearsley on the subject of the electrical driving of rolling mills were read at the Summer Convention of the American Institute of Electrical Engineers. A num-

Digitized by Google

ber of advantages possessed by electric driving over steam engines were pointed out, and the requirements of various conditions were considered. (Page 758.)

WE publish this week particulars of the courses in electrical engineering which are given in the leading University and other Colleges in London, in the same way as the provincial Colleges were dealt with in our last issue. We have endeavoured to indicate in each case the previous education expected of students, the nature and length of the course, the fees and the degrees of certificates obtainable. (Page 760.)

A CORRESPONDENT sends us a short article dealing with the dispute between the Commercial Cable Co. and the Newfoundland Government with regard to the refusal of the Government to ratify an agreement made with the company by the previous Ministry. (Page 762.)

THE accounts of the Acton Electricity Department for 1908-9 show a deficiency of £4,944.—There was a deficiency of £384 upon the working of the Bath Corporation electricity undertaking for the past year.—The tramway manager at Belfast has reported against the use of centre tramway poles on account of their obstruction to the general traffic.—The Local Government Board have repeated their refusal to grant the Bray Council a loan for expenditure incurred in past years.—September 15th has been fixed for the inauguration of the tramway service over Blackfriars Bridge.—Highgate Hill cable-cars have been discontinued and the work of electrification commenced.—Thefts of tantalum lamps to the value of £500 have taken place at Manchester.—Portsmouth Corporation electricity accounts for 1908-9 show a net profit of £3,930, of which £2,000 have been handed over to the relief of rates. (Page 763.)

LONDON COUNTY COUNCIL require motor-generators for tramway sub-stations; and large electrical extensions are to be carried out at Dudley and Londonderry. The sum of £25,000 is to be spent upon tramway and lighting extensions at Fremantle (W.A.); tramway extensions are to be carried out at Leeds; and the Australian Postmaster-General's Department invites tenders for large quantities of telephone materials. (Page 764.)

AN interruption in the electricity supply at King's Lynn occurred early on Saturday morning, due to three faults on the distributing system. The network was not entirely re-connected until Monday, and on Saturday night an important part of the town was still without electricity supply. (Page 766.)

THE Government have decided to drop the London Electric Supply Bill for the session. The Electric Lighting Acts (Amendment) Bill is to be proceeded with, and has been read a third time in the House of Commons, with certain additional amendments. (Page 766.)

SOME notes are given on the exhibits of electrical engineering interest at the Nancy Exhibition. (Page 767.)

THE tax on electrical and other illuminating apparatus in Germany comes into force on October 1st. It is to be paid by the manufacturer by means of tax stamps affixed to the packages of the articles concerned. In the case of imported articles, the tax is to be paid by the importer at the time of clearance through the Customs-house. The articles must be in closed packages, with the number and nature of the contents clearly marked on the outside. (Page 767.)

AMONG the specifications published by the Patent Office on Thursday last is one by G. Hookham for a method of compensating for the temperature error of mercury-meters by causing the effective length of a shunt resistance wire to be varied by the movement of a column of mercury. P. MacGahan has protected a process for coating copper wire with a thin film of insulating aluminium oxide, and a specification by the British Thomson-Houston Co. covers a process for the reduction of the higher oxides of tungsten. A lamp shade gallery with spring pins, which can be temporarily held outwards while the shade is being inserted, is patented by S. Falk, and the Grondal Kjellin Co., Ltd., and J. Härden have protected an induction furnace in which the lining acts as a secondary circuit to melt the charge in the first instance, thus avoiding the necessity for metal rings or an initial molten charge. The opposition to the grant of a patent to the British Insulated and Helsby Cables Ltd. and D. B. Saunderson for a process of welding wires and cables has been unsuccessful, and a patent has also been granted to Crompton & Co., Ltd., J. C. Macfarlane and H. Berge for a motor-generator set for supplying constant current, in spite of opposition. (Page 768.)

SERIOUS H.-T. ACCIDENT IN ITALY

A 3,000 volt Line fallen on the L.-T. Distribution Network

SOME particulars are to hand of a most deplorable accident which occurred on Wednesday last week at Olginate, a village of some 2,000 inhabitants, on the banks of the River Adda, a few miles south of Lecco, in the Lake Como district, Lombardy. As in the case of many other Italian villages in the mountainous regions, Olginate is supplied with electrical energy at a cheap rate from a neighbouring water-power station, the supply in this case being given at 3,000 volts over an overhead line from a power station at Lecco.

From the reports received up to the present, it appears that during a severe thunderstorm about eight o'clock in the evening of the 18th, when most of the street and house lamps were in use, one of the overhead high-tension wires broke in Olginate, and fell on to an overhead wire of the village lighting system, with the result that the wiring in all the houses and cottages was immediately raised to the full line potential of 3,000 volts. Ten persons were killed outright either in attempting to switch off the current or by coming in contact with the wiring, and twenty-nine persons were seriously burnt. Surface wiring is largely employed, and it appears that in many cases the wires caught fire and fell from the walls and ceilings, giving fatal shocks to the occupants of the rooms. All the lamps were, of course, extinguished, and there was quite a panic in the village. The resident electrical engineer telephoned the station at Lecco, and the supply was switched off. Firemen and soldiers arrived, and order was soon restored.

It is stated that the victims belong almost exclusively to the lower classes of the population, the effects not having been so serious in the houses wired according to modern methods.

The *Morning Leader* states that, according to the latest reports, the total number dead is 12, and that of the 29 injured, many, it is feared, will not survive. The same paper adds: "The responsibility for the disaster is now attributed to the fact that the transformers, the charge of which should be entrusted to an experienced electrician, had been left to a lad of 14, who at the moment of the disaster lost his self-control and, frightened, took no such precautions as would have avoided or mitigated the disaster."

Although most accounts agree that the cause of the accident was the falling of a high-tension wire on to the low-tension network, it is surprising that there was no earthed guard-net between the crossing wires to prevent this. The *Daily Chronicle* states that there was a great outburst of indignation against the electricity supply company, and that the company's representatives had to be guarded lest they should be lynched.

Central London Railway Extension.—It is announced that work will shortly be commenced on the extension of the Central London Railway from the Bank to Liverpool-street, for which powers have been secured in the present session of Parliament. Other improvements are also projected in connection with the Central Tube. The scheme includes the construction of a movable platform connecting the British Museum Station of the Central London Railway with the Holborn Station of the Great Northern, Piccadilly & Brompton Railway.

CORRESPONDENCE

ELECTRIC MOTORS v. GAS ENGINES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have pleasure in giving you, as near as I can, the particulars Mr. Horsnaill asks for, thus :—

(1) Average cost of gas, 3s. per 1,000 ft.
(2) Average cost of electricity, 1½d. per unit.
(3) H.P. of gas engine, about 4 B.H.P.
(4) Two electric motors, 2 h.p. each.
(5) Total outlay on electric installation, rather over £60.
(6) Original cost of gas engine also rather over £60. The engine would have been about eight years old when it passed away.

In so far as I am concerned, there is no need for further inquiry regarding the commercial advantage of the change; I have tangible proof of this. I regret I am unable to give more exactly the capital expenditures, but the following are fuller details, in reply to Mr. Horsnaill's inquiry :—

Gas Consumed.

Year.	Cubic feet.	Price.
1899	142,700	s. d. and s. d. 3 1 and 3 0
1900	162,100	3 0 ,, 3 2
1901	160,600	3 2 —
1902	169,200	3 2 ,, 3 0
1903	161,400	3 0 —

Electrical Energy Consumed.

Year.	Units.		Price.
1904.....	1,504	=	650 at 3*d.* 854 ,, 1*d.*
1905.....	1,797	=	385 ,, 3*d.* 1,412 ,, 1*d.*
1906.....	1,822*	=	418 ,, 2½*d.* 1,404 ,, 1*d.*
1907.....	2,254	=	464 ,, 2½*d.* 1,790 ,, 1*d.*
1908.....	1,922	=	449 ,, 2½*d.* 1,473 ,, 1*d.*

* The sum given in my previous communication should have been £10 3*s.* 11*d.*; a clerical error of mine—against the motor, however.

The current rate for gas is 2s. 7d. per 1,000 ft., subject to a rebate of 1d. and 2d. per 1,000 ft. for prompt payment.

One of the motors drives four lathes, a grinding machine principally for tools, a small drilling machine, and one small Root's blower. The second motor is a combined motor polishing machine.

The price I mention includes the two motors, starters, switches, fuses, wiring, &c., all my outlay, except perhaps a little for new belting and wood casing for one motor.

The gas engine was not new, but not very old, when I obtained it, and was sold to me as fully overhauled. The cost given above is exclusive of concrete base, and other extras.

I have no wish to be considered an authority on the merits or demerits of motors or gas engines, but besides the particulars mentioned by Mr. Horsnaill, it seems to me that others have to be taken into account, such as personality, assistance, the nature of the building, and the class of work being done. Cost of electrical energy as against cost of gas is not the only consideration. You wish finally to drive your tools, and where current can be got as conveniently as gas and water on anything like reasonable terms, motors are far superior to gas engines, if common sense is exercised in selecting and fixing them. I am now hastening to connect up more motors. Last January I connected an additional motor to a small blower direct, and it has already proved a great convenience. Last month I discarded a belt-driven grinder, and fixed a small motor, on which I placed a small emery wheel on each end of the spindle to grind tools, &c., and it works like a charm. This month I have got delivery of six motors, which I mean to attach direct to various tools, and for some time I have been on the outlook for a combined motor turret lathe; but so far I find any maker of such wants a fabulous price for one. It will be seen that I shall save a lot of shafting, pulleys, belts, &c.

Yours truly,

AN ABERDEEN BRASS-FOUNDER.

Aberdeen, August 21st, 1909.

ELECTRIC PASSENGER HOIST ON THE WETTERHORN

THE electric passenger hoist recently constructed up a portion of the Wetterhorn, one of the perpetual snow peaks of the Bernese Oberland, offers a number of features of engineering and general interest, for the height of the lift is 1,380 ft., and during the passage from bottom to top the car is suspended in mid-air. The lift, which was opened for public service in July of last year, is the first of its kind to be constructed. It starts from the base of the mountain, near the Wetterhorn Hotel and the famous Upper Grindelwald Glacier, some 5,500 feet above sea level, and therefore rises to a height of 6,880 feet above sea level. The height of the summit of the Wetterhorn is 12,150 feet.

The hoist is constructed on a system designed by Herr Feldmann, who superintended the contruction of the Barmen-Elberfeld suspension railway, but who died in 1905, and was unable to see the completion of the present lift. Two cars are suspended by means of four-wheeled trucks from two cables placed one above the other, and connected together by a pair of hoisting cables, so that when one car ascends the other descends, thus, to a certain degree, counter-balancing one another. By arranging the suspension cables above one another in a vertical plane, instead of side by side, increased stability of the cars, especially in high winds, is obtained. The other advantages claimed for the Feldmann system are a high speed of working and exceptionally low capital and working costs as compared with other mountain railway systems.

At the top, the hoisting cables pass round two winding drums, which are geared to a 45-h.p. motor. In Fig. 1, which gives a diagrammatic view of the cable-way, the two stations and one of the two cars are indicated, and the two suspension cables are in each case represented by a single line. The upper line represents

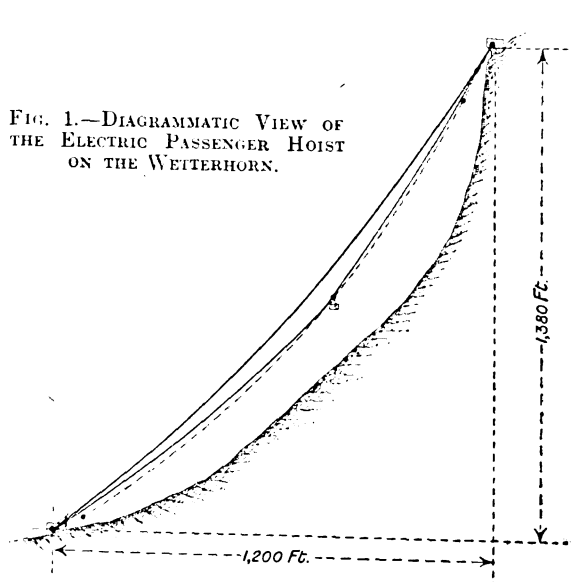

FIG. 1.—DIAGRAMMATIC VIEW OF THE ELECTRIC PASSENGER HOIST ON THE WETTERHORN.

the position taken up by an unloaded pair of cables, the lower, by a pair of cables with a car on them, in the position indicated, and the dotted line represents the path taken by the car. The steep angle at which

Digitized by Google

the ropes are suspended is shown in the figure, and also in Fig. 5.

The suspension cables are 1·93 in. in diameter, and weigh 7·4 lb. per foot. Each cable comprises 96 steel wires in five layers of 6, 12, 22, 28, and 27 wires respectively round a central wire. The two cables are spaced 2·9 ft. apart, while the distance between the two lines is 26 feet. Although the maximum load per cable was estimated at 13·8 tons, the cable used showed a tensile strength of over 154 tons under test, so that a factor of safety of 11 is obtained. To prevent any bending of these cables at the points of fixture at the upper station, each is supported in a movable bearing, as indicated in Fig. 2, which is a vertical section through the upper station. The bearing is semi-cylindrical in shape, with two rows of hard steel rollers between the fixed and moving portions, the fixed portion being supported at the end of a main horizontal member of the steel frame-work. The cable is provided at its extremity with a steel collar, which rests on an annular ridge in the moving portion. At the lower end the two cables of each line are connected together by a chain, which runs over rollers and through a traverse, as shown in Fig. 3. A weight Q of 18·5 tons is suspended from this traverse in a pit, and keeps the two cables in equal tension. There are three spur wheels in the traverse; the two outer ones, a and b, are free to rotate, but the middle one, c, is fixed, but capable of adjustment, so that any difference in the expansion of the two cables can be allowed for. When the two cables are equally loaded, the traverse is in the position a, b, c, and the weight hangs centrally. Should the cable S_1 stretch through being overloaded or for any other reason, the traverse will take up the position a_1 b_1 c_1 and the weight Q will then be displaced, so that the cable S_1 is relieved, and more load put on the cable S. Thus any weakening of either cable is automatically compensated for. To prevent either cable from slipping through the traverse on the breakage of the other, bolts pass through the links on either side of the fixed spur wheel. These are removed if it is desired to adjust the position of the traverse on the chain. If one cable breaks, the remaining one is quite strong enough to support the car.

The hoisting cables are 1·14 in. in diameter, and weigh 1·9 lb. per foot. Each cable consists of 90 steel wires, woven together in six strands, and has an actual tensile strength of over 43 tons, whereas the working stress is only 2·5 tons. By means of a cross-arm attached to the truck, the two cables are spaced horizontally at a distance of 5·4 feet. Each car weighs over four tons, including the truck, but excluding passengers, for which a further one and a quarter tons must be added. One of the most interesting features of the system is the elaborate automatic braking gear on the trucks, illustrated diagrammatically in Fig. 4. This works as follows:—Should one or both of the hoisting cables Z break, a relative movement of the two halves of the cross-arm, A and B, takes place, and this results in the levers i and i_1 being disengaged. The spring g then causes the eccentrics e and e_1 to turn, and to press the two halves a and a_1 of the conical grips towards one another, and, simultaneously, the lever f strikes the cam k. This releases the springs p and p_1 which force the two cone grips into the sleeves c and c_1 respectively. As the grips are already in contact with the cable, the springs only move through a very short distance, and exert nearly their full force on the brake. With these brakes it is possible to stop the cars, when running at full speed, in a distance of less than one foot, and this rapid braking is practical in this case as the hanging cable acts as a spring, and takes up the shock. Fig. 4 also shows the arrangement of the four running wheels and the guide wheels. The automatic brake can be operated by hand by the attendant. To reset the brake it is necessary to climb on to the roof of the car. The cable was supplied by the Felten & Guilleaume Lahmeyerwerke.

An idea of the surroundings of the hoist and of the difficulties which had to be overcome in its construction, is given by the following illustrations:—Fig. 5 is a view taken from the side, and shows the angle at which the cars travel; while Fig. 6 is a view looking up at the cars from below. In the latter photograph a portion of the famous Grindelwald Glacier is to be seen. Fig. 7 shows one of the cars arriving at the upper station which was constructed on a heavy concrete foundation in step-form, as can be seen from the sectional drawing of Fig. 2. The hoisting gear illustrated in Fig. 8 comprises two large sheaves, each over 12 feet in diameter and having six grooves. These are driven through gearing by a 45-h.p. continuous-current motor running at 750 r.p.m. The two hoisting cables from the one car pass into the station over two inclined guiding sheaves, each 9·8 feet in diameter, and then pass one-quarter the way round the first winding sheave on to the second,

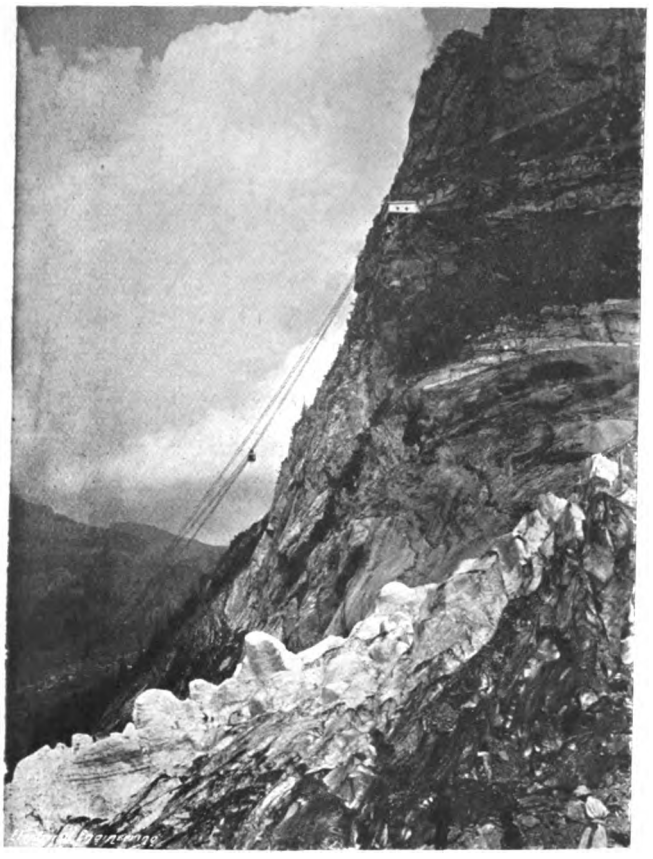

FIG. 5.—VIEW OF WETTERHORN PASSENGER HOIST FROM THE SIDE.

from the second to the first, and round this again to the second, and from that over the other inclined sheaves to the other car. The manner in which the motor is geared to the winding sheaves can be seen from Fig. 2. A hand-brake is provided, but this is not supposed to be employed when the cars are running, its object being to secure the gear when the hoist is not in use. An automatic safety-brake on the horizontal shaft of the gear comes into action if the cars run too fast, in consequence, for example, of a failure of the supply, if the motor or gear should be damaged, or if the attendant should fail to cut off the current at the proper time. This brake is magnetically operated, but can be applied by hand if necessary by the station attendant, who has indicators to inform him of the position and the speed of the cars.

The motor is shunt wound, and if the pressure across the terminals is too high it is automatically switched off and the brake applied. When this brake is employed the cars run about six feet before coming to rest. About 13 feet from the stopping-place the car comes in contact with a lever, which cuts off the current from the

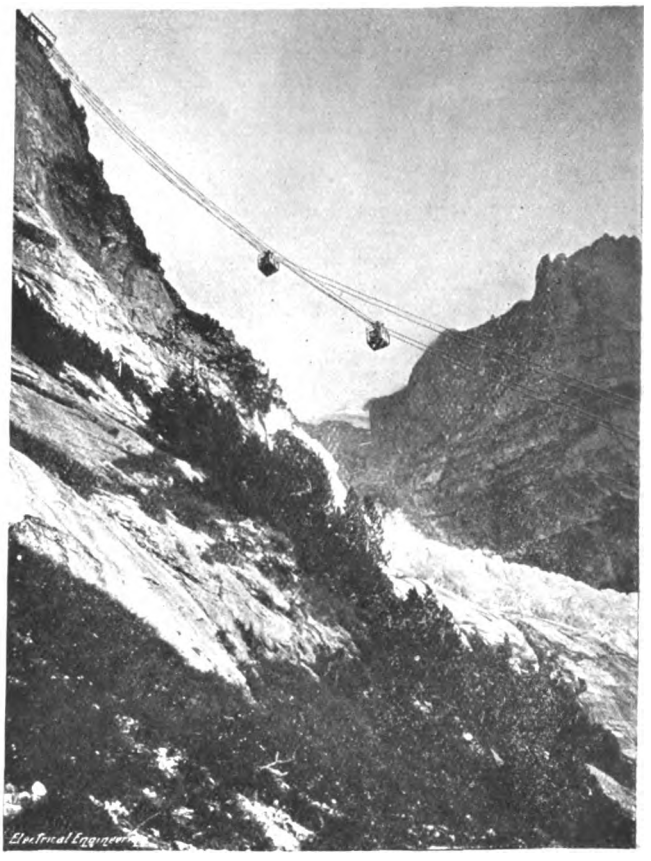

FIG. 6.—VIEW OF WETTERHORN PASSENGER HOIST LOOKING UPWARDS.

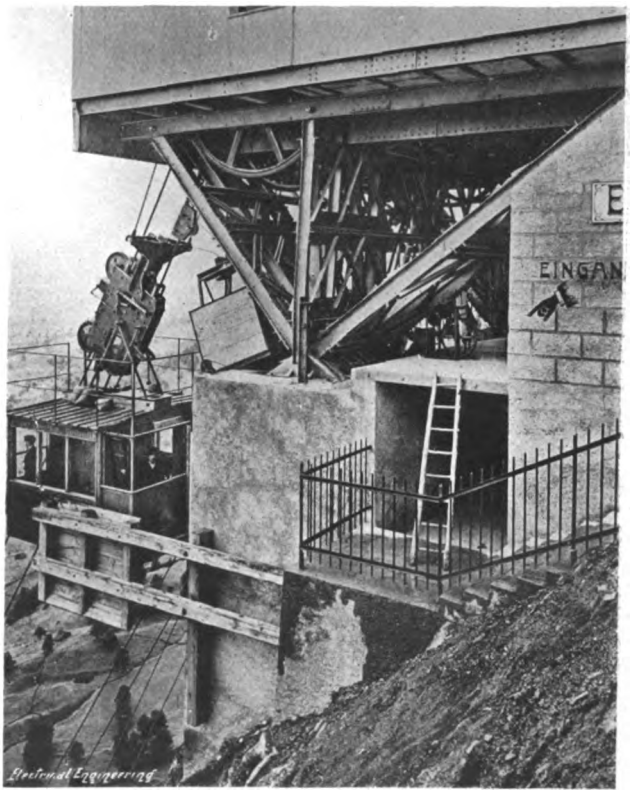

FIG. 7.—THE UPPER STATION OF THE WETTERHORN PASSENGER HOIST, WITH ONE OF THE CARS ARRIVING.

motor, and connects it across the full resistance, gradually cutting this out in steps, so as to bring the gear

Digitized by Google

gradually to rest. Power is supplied in the form of single-phase alternating-current at 2,400 volts from the Grindelwald generating station, and is converted to 800 volts continuous-current by means of a motor-generator set. This latter is situated in the lower station, with a 74 ampere-hour battery, which, when fully charged, is capable of running the hoist for 25 journeys.

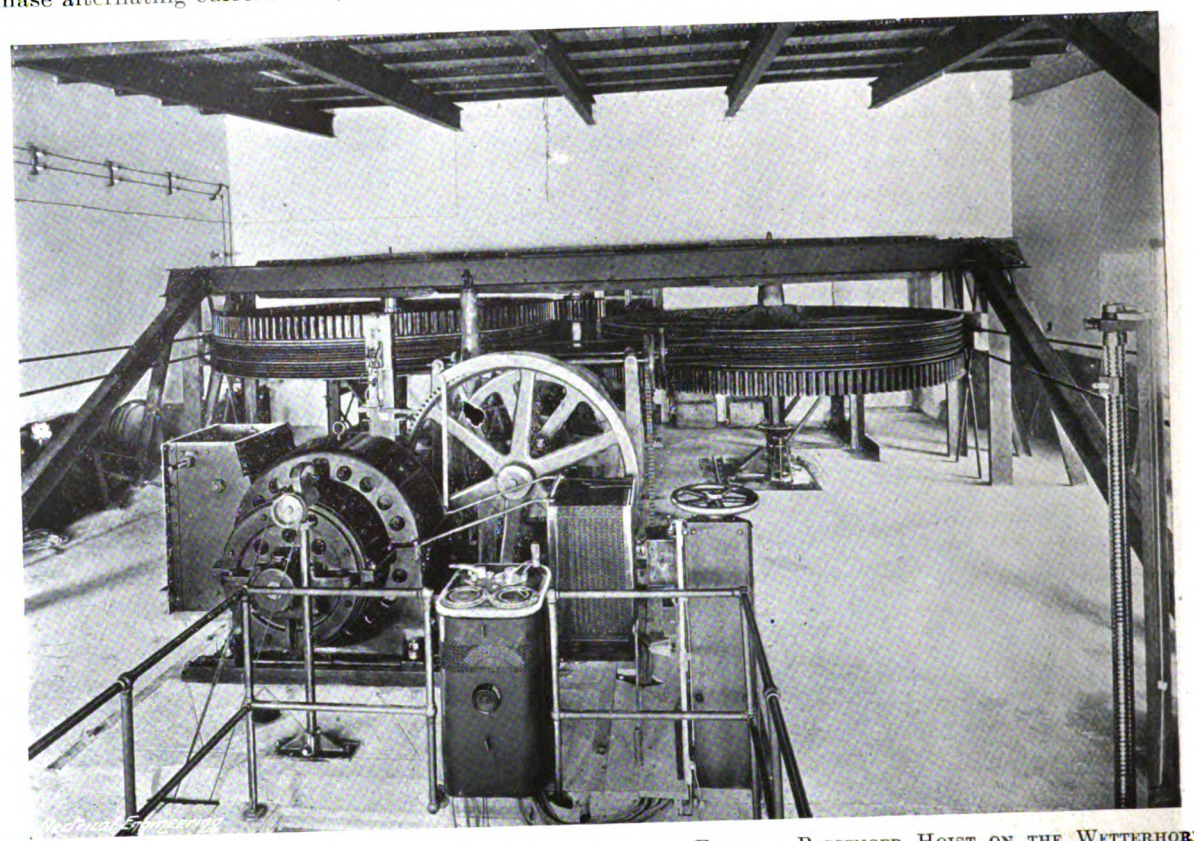

FIG. 8.—VIEW OF THE INTERIOR OF THE UPPER STATION OF THE ELECTRIC PASSENGER HOIST ON THE WETTERHORN.

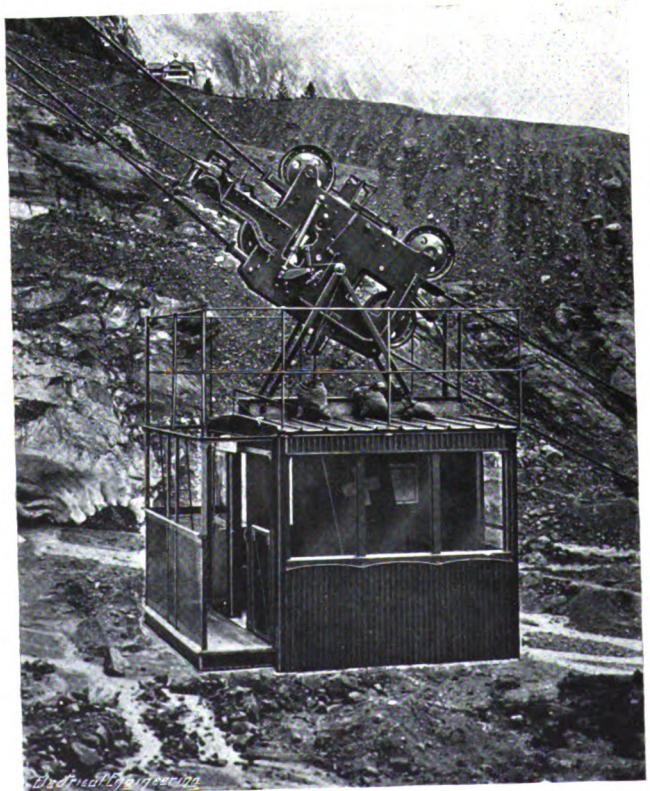

FIG. 9.—TRUCK AND CAR OF THE WETTERHORN ELECTRIC PASSENGER HOIST.

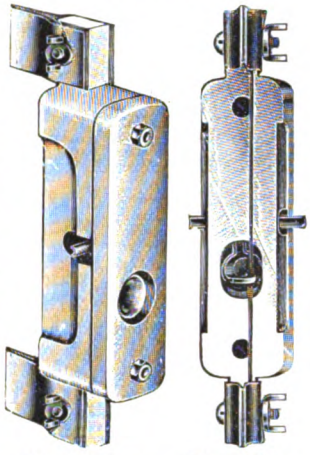
Fig. 9 is a view of the passenger car and truck. The car itself is about 10 feet square by 8 feet high, and has seating capacity for eight persons besides the attendant. Including standing room, the car will hold seventeen persons, however. As the angle of travel is very steep, the gradient at the top being about 200 per cent., the car is divided into two parts by a slot through which the cables can pass. A railing is fixed to the top of the car, so that the attendant can inspect the truck or reset the brake in safety.

Although there is little chance of a complete failure of power to operate the hoist, the winding sheaves can be manually operated. As a further precaution, a small emergency car, which can be let down the cables to either car, is provided. This car, which is shown in Fig. 2, is supported over a windlass operated by an 8-h.p. single-phase motor, but it can also be worked by hand. We are informed that the service has been most satisfactory, and that the hoist has been much patronised by tourists. If the present section proves to be a commercial success, the hoist will be extended to some considerable distance up the Wetterhorn, and it is expected that other well-known peaks will soon be provided with similar hoists.

The entire work of construction was carried out by the Giesserei Bern, a branch of the L. von Roll'schen Eisenwerke, of Gerlafingen, Switzerland, who have, within the last ten years, erected a large number of cable railways in Switzerland, France, and in other parts of the Continent. The electrical equipment was supplied by Messrs. Brown, Boveri & Cie, of Baden, Switzerland, and we are indebted to these firms for supplying us with the information and illustrations for the present article.



Overhead Wires in Australia.—At a recent meeting of the Electrical Association of Queensland, says the *Australian Mining Standard*, it was stated that the State had not even the same facilities for the use of overhead electric lighting wires as England, with its closer population, or the Continental cities. A committee was formed as a proposed deputation to wait upon the Minister, with a view to having these regulations amended.

AN INDICATING FUSE CARRIER

MESSRS. SIMPLEX CONDUITS, LTD., of 113 Charing Cross Road, W.C., are giving a considerable amount of attention to the development of their fuse and fuse-wire business, and the following notes with regard to their work in this direction, and description of a new indicating fuse carrier which they have just introduced, are of interest.

The fuse carrier (Hatry's patent) is a modification of the firm's standard design, there being an attachment added which gives a clear indication of the blowing of the fuse. Fig. 1 shows front and back views of the fuse carrier. The indicator, which is coloured red, appears at the hole in the front cover when the fuse is blown, the spring of the indicator being attached to the fuse wire by means of a hook. The wire is carried at the back well out of the way, and is clamped by two butterfly nuts as shown. The carrier can be used in the standard type and size of fuse-boards and clips, and only a very slight increase of price over that of the standard pattern of carrier is involved by the addition of the indicator.

Front View. Back View.

FIG. 1.—INDICATING PORCELAIN FUSE CARRIER.

Fig. 2 is a photograph of a large extruding press, which has recently been installed by the firm at their Garrison Lane works in Birmingham for the purpose of the manufacture of fuse wire. The total weight of the press is over 10 tons, the working pressure on the ram is 400 tons, and the press is fed by a vertical pump working at a pressure of 2 tons per sq. in. It has been especially designed for the work, and new safety valves and special facilities for enabling rapid recharging with the metal alloy from which the fuse wire is made have been provided. The metal is poured into the container, and maintained in a molten state by means of gas rings. The control is simple and effective, and the pump actuating the press is driven by an electric motor.

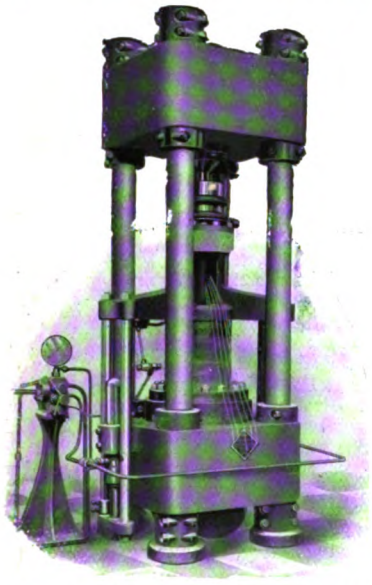

FIG. 2.—EXTRUDING PRESS FOR THE MANUFACTURE OF FUSE-WIRE.

BATTERY-OPERATED SIGNALLING APPARATUS

A SIGNAL machine, constructed to overcome the difficulties attendant on working signals by mechanical means when such signals are at a great distance from the levers working them, and also for operating signals automatically by track circuit, has been put on the market by Messrs. Siemens Bros. & Co., Ltd., of Caxton House, Westminster.

The essential feature of this machine is that only a small primary battery is used to lower the heaviest signal to the "clear" position, only a very small amount of energy being required. The machine can be fixed to any signal post, and can be worked either from a battery at the cabin, or by a local battery at the post controlled by a relay. The motor is operated by a few dry cells, Leclanché or soda batteries, and the "holding off" current is said to be practically negligible. The machine is self-contained in a rain and dust-tight case of cast iron, and is specially adaptable where slotting is necessary, as, for example, the case where "distant" signals are fixed under and controlled by "starting" signals operated from two cabins. A positive release to "on" position is claimed, there being no catches or brakes to hold the signal "off," and the signal arm cannot be lowered to the "off" position by anyone tampering with it, as the machine holds the signal arm at "danger" at all times except when current is sent through the motor.

The machine, which is illustrated in Fig. 1, can be attached to any part of the signal post. The upright rod working the signal, which is usually attached to the balance lever at the bottom of the post, is cut and attached instead to a crank on the outside of the machine. This crank is the only working part on the outside of the case, and is keyed to a shaft which passes through the case. On the same shaft is keyed the arm 929 (see Fig. 2), which carries at its end a pawl, 934, which engages with the teeth on the wheel 916, and which is connected by a rod on to a crank arm of the armature of the holding-off magnet 942. When the armature is held by the magnet the crank arm centre 939 is co-axial with the shaft carrying the wheel 916, and turns the pawl 934 into a locking

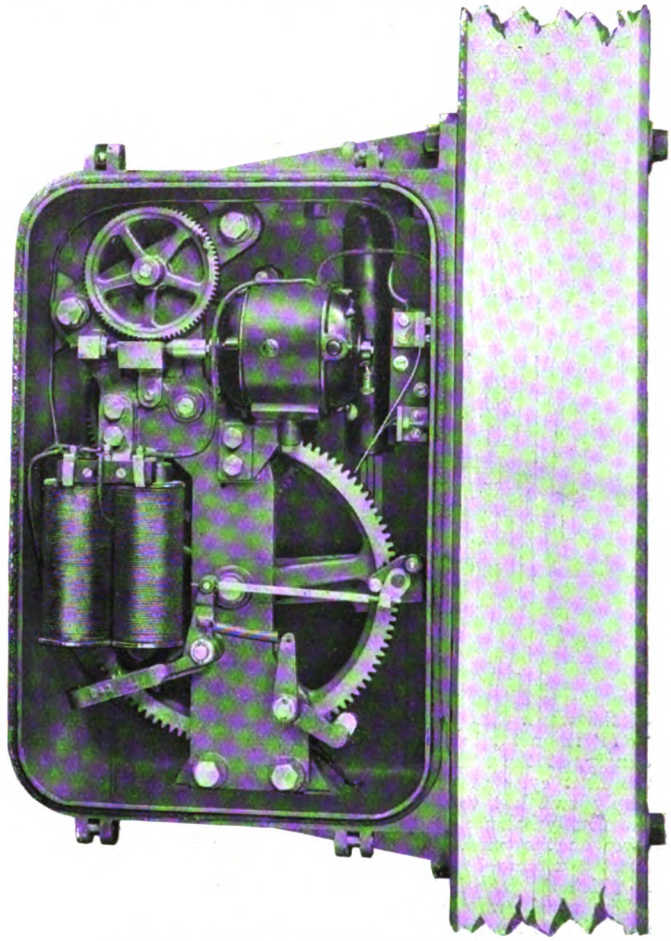

FIG. 1.—INTERIOR OF SIGNAL MACHINE. (SHOWN RETURNING TO "DANGER" POSITION.)

position, so that it is carried round with the wheel when the latter is caused to revolve by the motor. On the application of current the motor revolves until the insulated roller 932 lifts the contact spring 978, and thus automatically opens the circuit of the motor. The signal arm, however, is held "off" independently of this action, owing to the holding "off" magnet being energised from a shunt circuit.

When the signalman replaces his lever, or if by any other means the circuit is opened, the magnet becomes de-energised and allows the pawl to be released from the locked position and turn so as to freely pass by the teeth, thereby allowing the lever arm and semaphore to return to their normal position. In returning to the normal position the lever arm presses on a bell crank, 944, which is connected through a spiral spring to the armature of the holding "off" magnet. This is for the purpose of mechanically replacing the armature in readiness for the next operation. Only a very small current is necessary for the energisation of the magnet, it not being necessary to attract the armature from its fallen position. Another function of the spring is that, should the wheel 916 stop in such a position that its teeth will not allow the pawl to enter one of the tooth spaces, the spring is put into a state of tension when the lever arm presses the bell crank, and the strain that would otherwise come on the armature and connecting rod is taken up by the spring. As soon, however, as the wheel 916 begins to revolve, the pawl engages with the first tooth space passing it, and the armature is brought up to the poles of the magnet by the tension of the spring. To minimise the shock, when the signal arm returns to "danger," a suction dashpot is provided. This has an advantage over a compression dashpot, inasmuch as it cannot

Digitized by Google

prevent the signal arm from returning to danger should the escape passage become blocked.

By reference to Fig. 2 it will be seen that on switch Z being closed at the cabin, or by relay at the signal post, or by other means, current flows through the outer winding of coarse wire of the magnet, thence through the motor 480, switch 978, and back to the battery. It also flows through the inner winding of the magnet back to the battery. This excites the magnet and holds the armature up. The object of the coarse winding, which is in series with the motor, is to provide a more intense field when the arm is being moved, thereby making the holding up of the armature more positive. The inner winding of fine wire provides a sufficient magnetic field to do so when the motor has stopped, and the arm is at rest in the "off" position.

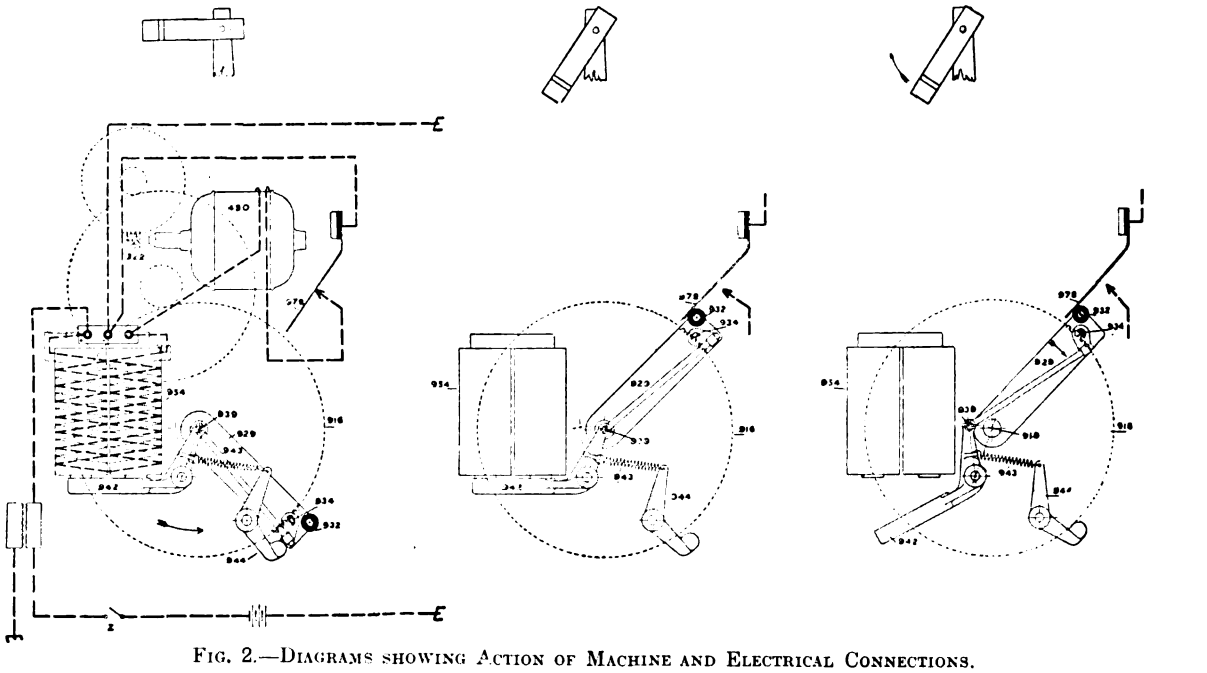

Fig. 2.—Diagrams showing Action of Machine and Electrical Connections.

The motor drives the gearing for moving the crank by means of the worm 922. Upon the circuit being opened the holding "off" magnet releases the armature, and the signal returns to danger, at the same time setting the machine in readiness for the next cycle of operations. The weight of the armature is amply sufficient to release the pawl from the wheel 916, but the counterbalance of the signal arm exerts a similar turning force on the pawl. The amount of power which the arm can exert to release the pawl can be adjusted by altering the angle at which the pawl is held in relation to the teeth.

The usual practice in working these machines for automatic signalling is to employ motors requiring a relatively low voltage, worked by a few cells locally at the signal post, and controlled by a relay also at the signal post, the relay being connected electrically with another battery at the cabin by means of a telegraph line wire, or to a track circuit. In this case, the resistance being low, motors requiring, say, 12 volts, are used, 12 Leclanché or dry cells being sufficient to maintain this voltage while the motor is working. For working distant signals, a central battery at the cabin is employed, and, instead of using 12-volt motors, 24-volt motors taking 1·25 amps. or 30 watts at full load are employed.

With a view to ascertain the life of the "Siemens-Obach" dry cell when used for the battery working this machine, tests have been carried out over a considerable length of time; 24 "Siemens-Obach" cells, size "M," connected in series, are required to give a pressure of 24 volts at the motor terminals when a current of 1·25 is passing—*i.e.*, when the motor is running, after overcoming the line resistance. The time taken to lower the signal is about eight seconds. Assuming the signal machine to be operated twice during the hour throughout each day of 24 hours, and being held in the "off" position 10 minutes at each operation, the battery would, we are informed, continue to supply current not differing by more than 10 per cent. from its original value for 120 working days. If a still higher E.M.F. of 30 volts were employed, the requisite number of cells would be 28, and the battery would, it is stated, be efficient for 200 working days under the same conditions.

These machines may be profitably used for working the signals at wayside stations, and the points, if any, can be operated by ground levers controlled by a key in combination with the signal switches, assuring complete interlocking. The machine is fully protected by patents in this country, and foreign patents are pending.

ELECTRICALLY DRIVEN ROLLING MILLS

TWO Papers on the electric driving of rolling mills were discussed at the annual Convention of the American Institute of Electrical Engineers at Frontenac, New York, one by Mr. E. Friedlander, and the other, which was more particularly devoted to the motors themselves, by Mr. E. W. Yearsley. In the first Paper it was remarked that the introduction of electric drive has made it possible to clear up many points in regard to the power required for rolling different shapes of steel, and, moreover, the operator is able to see at a glance the work done by each pass. The electric roll drive has also taught us how to get the best relation among rotation masses, speed, time, and horse-power. It has helped the roll designer to calibrate rolls in such a manner that the power characteristic for all the passes is uniform, thereby avoiding high power peaks, decreasing the size of the prime-mover, and reducing first cost and fuel consumption.

The wattmeter warns the roller of bearings or rolls becoming tight and hot, or that steel is causing excessive friction in the passes, often due to overfilling, cold steel or faulty calibration, thereby guarding against damage to the rolls and bearings. The meter indicates that lower heat, greater elongation, and especially change of profile in different directions, increase the power required at the rolls much more rapidly than do chemical hardness, high tensile strength, or larger draughts. The meter also shows that it is not the higher percentage of carbon in steel which requires more power in rolling, but the lower temperatures at which this steel has to be rolled, and also that an increase in width of the steel shape requires more power than a decrease in height. By means of the meter, too, it can readily be seen that rolling "squares" and "rounds" takes per square inch displacement much less power than shapes with large peripheries and many flanges, as the latter cool off quickly and cause much friction in the rolls. Tests on rail-mills have shown that the foot-pounds per square inch of displacement gradually increase the nearer the rail is to the finishing pass, partly due to the greater density and rapid cooling of the steel, especially at the thinner flanges near the finishing pass. Whenever required, exact power consumption can be given for each phase of rolling.

The ideal motive power for rolls should drive them slowly when the steel enters and should drive the roll faster as the piece lengthens. The reciprocating engine will do just the reverse; namely, run very fast without load and slow down as the load increases, finally stopping if the load becomes too

Digitized by Google

great. The maximum torque of reciprocating engines is fixed by the size of the cylinders and the pressure; it cannot be increased no matter how much steam or gas is available. For this reason most mill engines are made very large and often run with only half load, causing high steam consumption per horse-power, their most economical cut-off being at full load.

For this work the characteristics of the electric motor are much better. Even with double its full torque, the efficiency is good and the motor will not stop, but will take more and more current, finally becoming overheated and burning unless properly protected. If desirable, its speed changes from no load to full load can be made small. The current can also be limited to a certain maximum, without stopping the motor, in this manner preventing excessive strains and probably serious breakdowns.

Where high speeds are necessary, motors can be direct connected to rolls, increasing the energy of the rotating parts and at the same time decreasing the size of motor, the power required, and the fuel consumption. Heavy reciprocating engines cannot run at such high speeds, and must be connected to the rolls by means of gears, ropes, or belts.

In the case of three high non-reversible mills with flywheels, while the steel is being rolled, both the motor and the flywheel should furnish the power, but as soon as the steel leaves the rolls the motor should accelerate the rotating masses to the same speed before rolling. The time available and the number of revolutions will determine the size of the motor more than anything else. It has been observed that on blooming and roughing mills, where the pieces are very short and the intervals long, rotating masses supply the largest part of energy during the rolling period, and should therefore be large. The reverse takes place at the finishing passes, where pieces are long and follow each other rapidly. Heavy rotating masses would in this case be useless, and would even require larger motors for their quick acceleration.

The total motive power required in a steel plant is changeable and fluctuates continuously, the average in many plants being often below one-fourth of the total horse-power installed in motors. Electrically-driven rolling mills will, however, demand considerably larger power stations to take care of the large currents, especially when all the motors happen to be overloaded at one time, as, for instance, when rolling cold steel. The short, high-peaked current demands should be kept off the power station as much as possible, and only the average current be supplied. By means of storage-batteries or flywheel sub-stations the occasional large demands for current can be taken off the station and supplied from these two sources, where it is stored up when the current demand is below the average. The exchange of current from one motor to another, in connection with electric roll-drives, is often considerable and should not be overlooked.

With regard to the electric reversing mill, it is a fact that soon after its first appearance the use of reversing mills became more general, especially in England and Germany. In those countries, small quantities of one kind and shape of material are rolled, and the cost of the large number of rolls required and the saving of time in changing rolls are probably the chief reasons for using the reversing mill, where many different sections can be worked with the same rolls. The absence of the heavy and troublesome lifting tables is also a welcome feature, especially when pieces rolled are very long. In a reversing mill the operator is able to draw steel slowly into the rolls and "speed up" while the piece lengthens, making a great advantage in rolling steel.

With the use of electric motors in place of reciprocating engines, the problem of reversing rolls becomes much simpler and better, in regard to manipulation, fuel consumption, and cost of maintenance. Operation of electric-driven reversing mills is nearly automatic; no skilled operator is required and all danger to the motor and the mill is eliminated. The speed of acceleration is prearranged, and no matter how fast the operator moves his levers, the maximum current and the speed are limited. Reversing is done with the least shock to rolls and couplings.

As for other mill work where power and speed variation are considerable, the direct-current motor, on account of its load and speed characteristics, is better adapted for driving rolls than the alternating-current motor. For reversible roll-drives it is used exclusively. There is no reason why the direct-current motor should give any more trouble than the direct-current generator at the power station. Four years' experience has shown that the wear of the commutator and the cost of maintenance amount to practically nothing. The transmission of large low-tension currents is much more serious, especially when tens of thousands of horse-power have to be supplied and the distance of the motors from the station is considerable. The use of higher direct-current voltages in connection with large rolling-mill motors should be satisfactory; but no doubt high-tension alternating-current transmission and induction motors direct on the line will be generally employed, especially in new installations. Where conditions demand it, the induction motor characteristics can now be made nearly similar to the compound-wound, direct-current motor. However, much of its simplicity and efficiency will be sacrificed in doing this.

Whether direct-current power stations and direct-current motors are used, or alternating-current stations are installed for high-tension transmission with alternating-current motors directly on the line or fed through transformers, or direct-current motors are supplied from an alternating-current station through converters, or motor-generators, batteries, or flywheel sub-stations, is a matter of detail. No doubt any one of these systems will give satisfaction if properly designed and installed.

In the second Paper, Mr. E. W. Yearsley emphasised the importance of protection in the steel mill, where conditions are necessarily uncleanly, and electrical apparatus must work in the midst of dust, moisture, and gases. Large motors should be enclosed in solidly built tight compartments, ventilated by clean air if necessary, or should be of the totally enclosed type. Considered economically, the author believes main-motor drives to be superior to engine drives, even when power must be derived from a steam engine-driven generator plant fed by coal-fired boilers. Steam losses due to condensation and leaky valves and rings are surprisingly large, but usually escape definite measurement. Then in the usual rolling-mill engine, very little expansion is utilised, and it is not likely that attempts to refine such machines are satisfactory. Where water power or waste gas is available there is no question of the greater economy of electric drive.

The controlling apparatus for mill service is usually the weak part of the system; it is much less satisfactory than the motors. Mechanical strength and simplicity are the main points to be observed in designing this apparatus. Heavier and more mechanical switches and circuit-breakers, better protected and more durable rheostats, and more dependable automatic controlling devices, requiring less attention, are badly needed. This is a problem more difficult of solution than improvement of the motor, but no less necessary.

For large main-drive motors the advantage of continuous running at constant speed is so great that it would appear advisable to make the design of the mill suit the characteristics of the motor, and avoid the extra expense and complication of devices like the reversing drive. The tendency has been to build a machine and then to couple on a motor somewhere to drive it. This mistake, while not so frequent as formerly, is still made.

There seems to be no great difficulty in designing mills for continuous-running motors. By combining such motors with a suitable flywheel, it should be possible to keep the line load sufficiently uniform.

The importance of low armature inertia for reversing motors is now well recognised, but designs could be improved by still further reduction in speed. The writer is decidedly against the use of high-speed motors for any kind of mill service, and believes the extra cost of slow-speed machines well warranted. Electric motors subject to excessive vibration communicated from the gearing and other parts of the machine should be protected by a flexible coupling.

For mill apparatus which must be handled directly, especially for direct-current apparatus, the writer favours a maximum of 250 volts. Safety of employés requires that with higher voltages special guards be provided to isolate the apparatus.

Alternating-current and direct-current motors and apparatus both have their advantages for steel mill installations. Local conditions must determine which is superior. Unless transmissions are too long, the author favours a direct current installation, especially if the plant has many machine tools.

Telephones in the Transvaal. Quoting from the *Natal Mercury*, the *Board of Trade Journal* states that further extensions and improvements of the Transvaal telephone and telegraph services are in hand. Every town not yet linked up with the telephone system is to be brought into it, and the main trunk lines are to be carried to every point where the railway lines cross the border, with a view of preparing the way for the ultimate extension to the coastal ports and Bulawayo. It is regarded as certain that the Union Government will find telephonic communication between Cape Town and Pretoria absolutely essential under the proposed arrangement by which Parliament will meet at a place so far removed from the administrative centre. The scheme contemplates connections with farmhouses, and the establishment of call offices at convenient centres in rural districts. It is estimated that the coast extensions definitely undertaken will cost £250,000.

ELECTRICAL ENGINEERING EDUCATION

III.—COLLEGES, &c., IN LONDON.*

As is the case in the provinces, there are colleges and institutions of very varying character at which courses in electrical engineering are given. Some of these, formerly entirely distinct, are now incorporated in the scheme of the University of London, such as University College, King's College, and the East London College. The Central Technical College of the City and Guilds of London Institute at South Kensington, which now forms the engineering section of the new Imperial College of Science and Technology, ranks also as a school of the University of London. The Finsbury Technical College was also founded by the City and Guilds of London Institute, and is one of the oldest institutions of engineering instruction in the country. In addition to these more or less interconnected organisations, and some others of an independent nature, there are a number of institutions or polytechnics in various parts of London, where evening and day classes of various grades are held, and most of these also have well-equipped educational laboratories. Following, however, the course taken in our notes on the provincial colleges, &c., we shall make no attempt to describe the laboratory equipments, but shall endeavour to indicate the main characteristics of each institution, and the course of instruction there given. We have grouped those more closely connected with the University of London together for the sake of convenience, but neither is their order, nor the order of the various polytechnics and other establishments which follow, to be taken as any indication of precedence or relative merit.

University College.

University College (Gower Street, W.C.) is now incorporated with the University of London. It has for some time possessed an electrical engineering department under the direction of Prof. J. A. Fleming, F.R.S., who is assisted by Mr. W. C. Clinton and a staff of demonstrators. Mr. H. M. Hobart is lecturer on dynamo design.

Students who go through the complete electrical engineering course of three years can obtain the University of London degree of B.Sc. in engineering, and the college diploma. Degree students, before beginning their courses, should have passed the matriculation or school-leaving examination of the University, or some examination accepted in lieu of it. Students who have reached the standard of matriculation, but, owing to some special reason, have not passed the examination, can begin their engineering course in October, and pass matriculation in the next following January. It should be mentioned that for the London matriculation the following subjects are required in the case of engineering students: English, elementary mathematics, elementary mechanics or physics, and two of the following subjects: French, German, Spanish, or mathematics (more advanced). Diploma students should, as a rule, pass the college engineering matriculation examination (or some examination accepted in lieu of it) in the May or September preceding their entry to the college. Students who have not passed the college engineering matriculation examination or some exempting examinaton may be admitted to a diploma course in engineering upon producing evidence satisfactory to the Dean that they are able to follow the course, and will be required to pass the college matriculation examination within twelve months of the time at which they begin their diploma course. The composition fee for the three-year course is 120 guineas, which is paid in three instalments—namely, first year, 45 guineas; second year, 40 guineas; third year, 35 guineas. For students who have already completed part of their training elsewhere, special courses are arranged, extending over one or two years, as the case may be. The department of electrical engineering and all the departments of the faculty have excellent facilities for post-graduate and research work. The accommodation provided for the electrical engineering department, and that of all the engineering departments, was doubled two years ago, and the extensions were opened in 1908. The equipment of these extensions is of the latest, and has been provided largely by the generosity of former students of the college. The electrical engineering department has a licence from the Postmaster-General for a wireless telegraph plant and antenna, practical instruction is given in this subject, as well as courses of post-graduate lectures. Scholarships are awarded to electrical engineering students.

King's College.

King's College (Strand, W.C.) is also connected with the University of London, its incorporation with which will be complete next January. The faculty of engineering is under Prof. D. S. Capper, and Prof. Ernest Wilson is professor of electrical engineering, assisted by several demonstrators. The courses are arranged to give preparation for those wishing to take the London degree of B.Sc. in engineering. The matriculation examination of the University, of which some particulars have already been given, should be passed before commencing the course. For engineering students it is very important that the subjects taken for the matriculation examination of the University should include mathematics (more advanced), and a science subject, otherwise the examination is not accepted by the Institution of Civil Engineers in lieu of their own studentship examination. They can then be registered as internal students of the University of London, and eligible to take the intermediate examination in the College.

Either a four-years' course, the winter sessions being passed in the college, and three summer sessions in "Works," may be taken, or a three-years' continuous college course. The four-years' course has been arranged, so that students who show sufficient progress may after one complete year at the college, during six months in each ensuing year, undergo a course of practical training in some engineering works. In order to carry out this arrangement, a number of places have been put at the disposal of the college by well-known engineering firms, and to these places students may be nominated under certain conditions. By this means the practical and the scientific training will proceed side by side, and the opportunity will thus be given for a complete engineering training under the most favourable conditions, while at the same time the student will be able to qualify for the B.Sc. degree of the University of London, or for the college certificate and associateship.

An entrance fee of £5 5s. has to be paid, and the tuition fees for the regular course amount to £50 per annum, and £1 5s. per annum laboratory fees.

Students can be admitted to portions of the courses by special arrangement. Three- and four-year evening courses are also held.

The City and Guilds of London Institute.

The Central Technical College.

The Central Technical College of the City and Guilds of London Institute in Exhibition Road, South Kensington, is, as has been already stated, a "school" of the University of London in the Faculty of Engineering, and also forms the engineering section of the Imperial College of Science and Technology, which was incorporated in 1907 with this college, and the then existing Royal College of Science and the Royal School of Mines as a nucleus. For many years before its affiliation with either of these bodies, it was famed as a centre for electrical engineering education, and the pioneering work in this direction of the late Prof. W. E. Ayrton, F.R.S., will always be a landmark in the history of the subject. The ordinary course entirely at the college consists of three years' work, and a special feature is the large proportion of the tuition given in the laboratories, the lectures being rather for the purpose of aiding students in their laboratory practice than of forming distinct courses by themselves. The morning hours are mainly devoted to lectures, and exercises in connection with the lectures, whilst the afternoons are usually spent in the drawing offices, workshops, and laboratories. The programme is arranged so that students can take the examinations for the London B.Sc. degree in engineering, but is not absolutely confined to these requirements, the aim being more to give a sound and useful training than merely to provide for examination passing. The head of the electrical engineering department is now Mr. T. Mather, F.R.S., who is assisted by a number of demonstrators. Attention should also be drawn to the special post-graduate course in railway engineering, under the superintendence of Prof. W. E. Dalby, which include lectures on electric traction by Mr. Philip Dawson.

Entering students must be over 16, and those not taking the London University matriculation examination must pass a college matriculation examination of about the same standard. A diploma of associate of the City and Guilds of London Institute (A.C.G.I.) is awarded to matriculated students who have gone through a complete course of instruction as laid down in the programme, and have passed certain college examinations thereon. An honours diploma can be obtained by students who present a thesis embodying the result of original work during a fourth year of study. The title of Fellow of the Institute (F.C.G.I.) is conferred upon associates who have spent at least five years in actual practice and specially distinguished them-

* Part I, "The Universities of Cambridge and Oxford," and Part II, "Universities, Colleges, and Technical Schools in the Provinces," appeared in our last issue.

Digitized by Google

selves. A number of scholarships are obtainable for engineering students. The fee for the complete course to matriculated students is £36 per session. Special or partial courses can be taken by non-matriculated students at special fees.

The City and Guilds Technical College, Finsbury.

The Finsbury Technical College (Leonard Street, City Road, E.C.) of the City and Guilds of London Institute is one of the oldest centres of instruction in electrical engineering in the country. Both day and evening courses are given. The day courses cover a period varying from two to three years. The college is provided with laboratories and workshops, and the scheme of instruction is of an intermediate grade; it occupies the position of a finishing technical school for those entering industrial life at a comparatively early age; of a supplementary technical college, for those who, having had some industrial experience, desire to qualify themselves to become foremen or managers; and of an intermediate college in the educational scheme of the Institute leading up to the Central Technical College. A certificate is awarded by the Institute to students who have passed through one of the complete day courses of instruction with sufficient merit. The age of admission to the day department is over 14 years. There is an entrance examination once a year in September, and the fee for the session is £20 if paid in advance. The principal is Professor Silvanus P. Thompson, F.R.S., who is himself professor of electrical engineering, and is assisted by several demonstrators. The professor of mechanical engineering is Dr. E. G. Coker. There are several scholarships open to engineering students.

East London College.

The East London College (Mile End Road) was admitted as a school of the University of London in 1907, and the electrical engineering courses, which are under Prof. J. T. Morris, are arranged for students who take electrical engineering subjects and in preparation for the final B.Sc. examination in engineering, pass, and honours. Students joining the college must be not less than 16 years of age, and must satisfy the principal that their general education is sufficiently advanced to enable them to take the prescribed course of study which they desire to follow. The work of the department consists of a three years' course—the first year's work being general electrical engineering; the second year's, two courses, one on instruments and testing, the other on dynamos, motors, transformers, and electric traction; the third year being devoted to a more advanced study of these subjects. In conjunction with the lecture courses, laboratory courses and work in the drawing office have been arranged, to train the student in practical electrical engineering testing, and in the design of electrical machinery and apparatus. The fee for the session is ten guineas. Evening courses of instruction are also given in preparation for the same degree, and facilities are offered in the laboratories for research and experimental investigation.

The Electrical Standardising, Testing, and Training Institution.

The principal difference between the electrical engineering course of the Electrical Standardising, Testing, and Training Institution (Faraday House, Southampton Row, W.C.) and elsewhere is the affiliated works arrangement, by which every one of the students who passes through the theoretical course satisfactorily is sent for two years to engineering works, alternating with the college years, thus realising the much recommended "sandwich" system. The institution keeps in touch with the students by means of visits to the works by one of the staff, and also by each student in works sending a monthly report to the institution; the managers of the works also send in reports each month upon the students.

An elementary mathematical examination has to be passed by entering students, and the course, which occupies four years, is arranged as follows: First year at Faraday House, second year at engine manufacturers, third year at Faraday House, fourth year at electrical manufacturers or power house. The post of principal is now vacant owing to the recent sudden death of Mr. H. E. Harrison. Dr. Alexander Russell lectures in mathematics, and special lectures are given by Mr. H. M. Hobart, Mr. W. R. Cooper, and Mr. J. B. C. Kershaw. The fees are inclusive of everything, and no extra payments have to be made to the works to which the student is sent. The amounts are as follows: First year, thirty-five pounds a term; second year, seventy-five guineas the year; third year, twenty-five guineas a term; fourth year, fifty guineas the year.

The Northampton Institute.

The principal feature of the training in electrical engineering to be obtained at the Northampton Polytechnic Institute (St. John's Road, Clerkenwell, London, E.C.) is the way in which the commercial experience and education work of the institute are interlaced. The course occupies four years. In the first year, which is to a great extent preliminary, the student is put through a full session's work at the institute, and at the end of that period, if he be an undergraduate of London University, he should take the intermediate examination for the degree of B.Sc. in engineering. The second and third year's work consists of six months' training at the institute during the winter, and two periods of approximately six months each passed in commercial workshops during the summer. The fourth year's work is entirely at the institute, and extends over a complete session. Negotiations with various manufacturing firms have resulted in all the second year's men, who qualified for admission to the third year during the past five years, being placed in good commercial workshops for the summer upon advantageous terms. The works to which the students are sent include some on the Continent, as well as in this country, and it may be mentioned that at the present time several are working on the Italian State railways. The principal, Dr. R. Mullineux Walmsley, who is also the head of the electrical engineering department, makes a tour himself every summer, and visits all the works where his students are engaged. Dr. C. V. Drysdale is the associate head, and is assisted by a number of permanent lecturers and demonstrators. Mr. H. M. Hobart also gives some of the lectures. In the electrical engineering section, besides the training incidental to the ordinary work in electric lighting and power distribution, special courses are given in electric traction and electro-chemistry. The advanced students, especially in their fourth year, specialise in these subjects.

Entering students should have received a sound preliminary education, either in good secondary schools, or in the higher elementary schools established under the Board of Education. The courses are intended for those who desire to obtain a good technical training in engineering before being apprenticed to engineering works, or having been already engaged in actual engineering work are desirous of consolidating and extending their knowledge of the fundamental principles underlying such work and the most recent applications in particular directions, or are desirous of benefiting by the instruction provided, with a view to proceeding later on to the highest technical instruction which can be obtained.

Before being admitted to the courses, students should be not less than 15 years of age, and will be required to pass an entrance examination. The fee for the electrical engineering course is £15 per session for the first and fourth years, and £11 for the second and third years. Evening classes are also given.

The South-Western Polytechnic.

Electrical engineering courses are given at the South-Western Polytechnic (Manresa Road, Chelsea) for both day and evening students. The regular three-years' day course includes preparation for the engineering degree of the University of London, and it is also possible for evening students to take the same degree. Special courses are also arranged for the examinations of the Institution of Civil Engineers for Studentship and Associate Membership. Some of the courses form suitable preparation for some of the honours examinations of the City and Guilds of London and the Board of Education. The syllabus of any particular body is not slavishly followed, but the amount of ground covered enables a student to sit for a number of public examinations if he wishes to do so. A number of special courses are arranged for students engaged in or preparing for engineering work of various kinds. In almost all of these a class in technical mathematics, conducted by an engineer, has a place. A special feature is made of mathematics for engineering students, and it has been found to be most valuable in rendering the technical teaching effective. It is often asked from what avocations are the bulk of the students drawn, who take up advanced work. A large proportion consist of draughtsmen, assistant engineers in central stations, foremen, assistants in engineers' offices, and apprentices who have followed a consistent course of scientific study. There are also quite a number of university graduates and students who have gone through three-year courses in pure science at various London colleges, and who come to this institute for special technical work.

Entering students must be over 16, and before being admitted to a complete course are required to pass an elementary entrance examination. Certificates and diplomas of various grades are given to those going through the courses satisfactorily. The fees vary from £7 10s. to £15 per session, according to the number of hours per week. Mr. A. J. Makower is head of the electrical engineering department. Evening courses in electrical engineering extending over four years are also given, and special arrangements may be made for students engaged in central stations, whereby they may attend in the day during those weeks in which they are on night duty. Courses will be found suitable for students wishing to sit for the elementary, ordinary, and honours grade examinations in electrical engineering and the examinations in wiremen's work of the City and Guilds of London Institute, and for the evening science exhibitions in electrical engineering offered by the London County Council.

Battersea Polytechnic.

The Battersea Polytechnic provides in the day technical college a course in electrical (including mechanical) engineering extending over either three or four years, according to the capability of the student on entering, admission being restricted to students

Digitized by Google

of 16 years and upward who pass the entrance examination held previous to the commencement of the session in September. Students passing the full entrance examination enter directly into the first-year diploma course, and after passing the examinations at the end of their second and third years are awarded the Polytechnic diploma in electrical engineering. Students not sufficiently advanced to take the first-year course for direct entry are eligible to enter the preparatory course, and may enter the first-year diploma course at the beginning of their second year. The fees for the above courses amount to £12 12s. per session of three terms. The ordinary three-years' course covers the work in electrical engineering required for the London B.Sc. degree in engineering. The head of the electrical engineering department is Mr. A. W. Ashton. Extensions to the laboratory equipment are in progress, which will be available during the coming session.

The Borough Polytechnic.

The Borough Polytechnic Institute, 103 Borough Road, S.E., is chiefly devoted to evening classes. The courses of instruction in electrotechnology are arranged to cover a period of several years. For students who do not possess any theoretical knowledge of electricity, a first-year course has been drawn up, which deals with general elementary principles. The second-year course is devoted to the more technical applications, including electric wiring, and is only open to those students who can produce evidence of a fair knowledge of the elementary principles of electricity and magnetism. The third-year course, which is only open to students who have either passed through the second-year course in electrotechnics, or have passed the preliminary stage examination in electric lighting and power of the City and Guilds of London Institute, deals with more advanced subjects in electrotechnics, including continuous-current machinery, &c. The fourth-year course is a continuation of the third-year work, and takes up the principles of alternating-current working, &c. Advanced and honours courses in pure electricity are also arranged for those students who wish to specialise on the pure science side as distinguished from the technological. Students in the electrotechnical and pure science classes may present themselves for examination by the Board of Education (science and art department) and the City and Guilds of London Institute. The fees are low for all the courses. The head of the electrotechnical department is Mr. J. Henderson.

The Crystal Palace School of Practical Engineering.

Electrical engineering subjects can be included in the general engineering course given at the Crystal Palace Co.'s School of Practical Engineering. The electrical works is intended to follow the mechanical and civil courses, and to provide a minimum of training for the ordinary engineer, and to act as an introduction to the electrical engineering branch of the profession, should the student decide to follow it. The mechanical and civil engineering courses occupy one year, and a simple entrance examination in mathematics is required. The ordinary curriculum for the electrical section in the school is of two terms' duration, from the beginning of any term. During the whole period the student's time is devoted to special lectures; instruction, both theoretical and practical, in the shops and offices of the school; and directed practical work on the electrical installation in the Crystal Palace and grounds. Excursions are made by students to places of engineering interest. The complete fees for the mechanical and civil engineering courses, either of which may be taken alone, or the two one after the other, are £54 and £64 respectively, and the fee for the subsequent electrical course is £21 per term. Each student must also pay 10s. 6d. for an annual season ticket to the Crystal Palace. Certificates are given to successful students. The principal is Mr. J. W. Wilson, and it should be said that the school, which was founded in 1872, is one of the oldest institutions of engineering instruction in the country.

Telephone Apparatus in Australia.—Mail advices from Melbourne received this week state that the postal department is calling for tenders for the supply of 5,000 telephones of Australian manufacture. One of the conditions is that any design or pattern submitted will be considered by the department, but preference will be given to instruments conforming to the sealed pattern. The latter is similar to the Ericsson type, without any distinguishing name. On July 15th Messrs. O. C. Beale & Co., Messrs. Straeker & Hipsley, of Sydney, and other manufacturers of electrical plant, waited on the Postmaster-General. They contended that the adoption of the Ericsson type as the standard was not wise, it would entail the laying down of special plant purely for the manufacture of that class of instrument, which later improvements would render obsolete. There were already many improvements, they said, on the Ericsson instrument. If tenderers were allowed to submit the most up-to-date patterns they could manufacture, the industry was more likely to be established on a firm basis in the Commonwealth. Sir John Quick promised to consult the officers of the department as to whether the form of tender and specifications could be revised in the direction desired by the deputation.

THE NEWFOUNDLAND CABLE EMBROGLIO

(By a Correspondent.)

FOR the last two weeks a three-cornered fight has been in progress between the Commercial Cable Co., the Newfoundland Government, and the Anglo-American Cable Co., the subject of contest being a concession for landing cables in Newfoundland in favour of the first-mentioned combatant.

The Commercial Cable Co. claims that: it has the right to land cables in the colony; that the Government is bound to hand to it for 25 years all cable messages collected by its landline system; that, further, a yearly payment of $4,000 by the Government is due for establishing an office in St. John's, which, in the absence of this provision, would not have been established, as the company was debarred from dealing directly with the public; and that all material, &c., imported is duty free. The concessionaire claims to have concluded this bargain with the Bond Ministry, which was succeeded within a very short period by a new one, and states that it was not only final, being similar in all respects to others made with the Bond Ministry, but that the present ministry is breaking faith by not carrying out a contract made by its predecessors in office. Sir Edward Morris, the Premier of the Colonial Government, replies that "the present Newfoundland Government . . . were fully justified in taking time to consider the matter before embarking on legislation," and while freely granting the necessary land for the landing of cables, "the Government have not felt justified (not, however, without fully considering the matter) in granting by Act of Parliament the further concession attempted to be given in the agreement of 1909, namely, a monopoly for 25 years and freedom from taxation, whilst taxing the Anglo-American Co., doing business on the same street, $20,000 per annum."

It must not be forgotten that the Anglo-American Co. previously had the monopoly of telegraphic communication to Newfoundland, but the concession expired, and the Commercial Co. has been able to obtain landings for its cables, although it will not derive the additional advantages which the previous Newfoundland Ministry were about to accord it. Since it appears that the Anglo-American Co. is prepared to face competition on a fair basis, there is no doubt that the interests of the colony itself and the population are being best served by the refusal of the present Government to ratify the agreement with the Commercial Cable Co. It must be admitted that it is necessary to concede monopolies in some cases where the laying of a cable to a colony by a commercial body would not be justified by the traffic to be derived from it, but in the case of an important colony, this should not be permitted unless it have for its object the preservation or consolidation of British imperial interests.

Post Office Telephones.—A complaint was recently made that, where the telephone was under the control of the Postmaster-General, it was only open for the same period as the telegraph office, whereas the National Telephone Co. have no restrictions of that kind. A correspondent wrote to the Postmaster-General pointing out that a great advantage would be conferred upon users if the service could be extended beyond the hours of the ordinary telegraph business, and inquiry was made as to whether there was a possibility of this being done. The Postmaster-General has replied that at several of the more important Post Office telephone exchanges attendance is given at all times. In other cases, regard is had to the needs of the district, and if it is found that a service is necessary after the usual hours of telegraph business, arrangements are made as far as possible to meet the requirements. Where the National Telephone Co. are now giving continuous service, the Post Office will, in all probability, do so after the transfer of the company's system to the State.

Wireless Telegraphy.—According to the *Daily Telegraph*, active steps are being taken with a view to the establishment of wireless stations along the South African coast. The Natal Government is negotiating with the Imperial Government on the subject, and it is thought desirable that a station should be established on the Bluff at Durban. It is practically certain that on the return of the Premier, the Natal Government will take definite steps in the matter. The scheme in view is the establishment of a line of wireless stations between Delagoa Bay and Cape Colony, and the importance is also being urged of a similar system on the West Coast.

The Marconi wireless station at Marien Bay, Nova Scotia, which is used for the Transatlantic service, was partially destroyed by fire on Saturday last. The tower was not damaged. It is estimated that the repairs will take at least six weeks. In the meanwhile, messages will be dispatched *via* the Cape Cod station in Massachusetts.

An influential committee has been formed at Chamonix for the purpose of constructing a wireless station on the summit of Mont Blanc. The idea of the proposed installation is to provide means for summoning aid for alpinists in danger on Mont Blanc and neighbouring peaks, and also to connect the Alpine districts of France, Italy, and Switzerland. We understand that there has already been a generous response to an invitation for subscriptions for this purpose.

CATALOGUES AND PAMPHLETS RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

IGNITION COILS.—A leaflet from Messrs. Siemens Brothers & Co. (Caxton House, Westminster), which forms a supplement to the company's general catalogue of ignition apparatus, describes special forms of ignition coils, both of the trembler and non-trembler forms, for use with dry cells, for which arrangement considerable advantages are claimed over accumulators.

FIRE EXTINGUISHER.—A system of first-aid fire protection is described in a leaflet from Messrs. Lund Bros. & Co. (78 and 80 Queen Victoria Street, E.C.). The principle adopted is to have water ready on the spot where fire is likely to break out. This is contained in specially constructed galvanised steel vessels, each containing 40 gallons, and provided with a suitable length of special 1 in. hosing, and nozzle with a cock for directing the jet on to the fire. The number of vessels used is proportionate to the area to be protected and to the number of floors or storeys in the building. The area that any one vessel will protect simply depends on the length of hosing. All the vessels are connected by a small copper pipe to a conveniently situated compressed air reservoir of 40 gallons capacity, charged only with compressed air by a small hand-worked air compressor. There is a small air valve on the air pipe attached to the top of each water vessel. The compressed air fills the reservoir and the whole system of piping up to the valve on each water vessel, so that the water vessels are only subjected to pressure when it is required to discharge them. In the event of fire only one small valve has to be turned on, and a powerful 60-ft. jet is instantaneously produced lasting 6½ minutes (six times longer than from the usual chemical extincteur). The system is so arranged that air leakage from the pipes and reservoir is eliminated. The pressure gauge on the air reservoir or connected thereto shows at all times the readiness of the apparatus. When any vessel is brought into use the fall of pressure at the reservoir may be made to ring a powerful fire alarm.

HEATING AND COOKING APPARATUS.—The A.E.G. Electrical Co., of South Africa, Ltd. (Caxton House, Westminster), the agents for the foreign department of the Allgemeine Elektricitäts Ges., of Berlin, have sent us a pamphlet containing particulars of this firm's heating and cooking apparatus, including kitchen utensils, dining-room accessories, water heaters, electric soldering irons, office sealing apparatus, and other novelties.

INDUCTION MOTORS.—A list from the Electrical Co., Ltd. (121-5 Charing Cross Road, London, W.C.), gives particulars of several lines of three-, two-, and single-phase induction motors with outputs up to 6 h.p. Both open and enclosed type motors are included in this list, and prices and particulars of starters, switches, and other accessories are also given. The figures refer to 50-cycle motors; particulars of motors for other frequencies will be given on application to the firm.

METAL FILAMENT LAMPS.—Three new lists relating to "Aegma" metal filament lamps are to hand from the Electrical Co., Ltd. The first of these announces several further reductions in the prices, and some new sizes. A 16-c.p. 60/130-volt lamp is listed at 2s. 9d., pear-shaped; and with a round bulb, 3s. The 25-c.p. 200/260-volt lamp is listed at 4s., pear-shaped; and the 32-c.p. and 50-c.p. lamps for the same range of pressure at the same price. A 100-c.p. 200/260-volt lamp at 6s., and a round bulb 400-c.p. 100/130-volt lamp at 20s., are also to be obtained. The efficiency of these lamps is from 1·1 to 1·2 watts per Hefner candle-power. The other lists refer to 1 watt per c.p. miniature lamps for use with accumulators, and to an improved pattern of the "Ideal" candle fitting.

METRIC AND DECIMAL EQUIVALENT TABLES.—Mr. S. N. Brayshaw, of 2 Mulberry Street, Hulme, Manchester, manufacturer of Brayshaw's patent hardening furnaces, milling cutters, steel washers, and rollers, and other engineering accessories and tools, has sent us three varnished cards with tables of decimal, millimetre, and temperature equivalents, respectively. These tables appeared originally in the firm's catalogues, and are in a very useful form. Mr. Brayshaw's name is printed in small, unobtrusive type, and no other advertisement of any kind appears on the face of the cards. These will be supplied gratis on application to anyone mentioning this journal.

SWITCHGEAR, &c.—A pamphlet from James Ferguson (61 Pollok Street, Pollokshaws, Glasgow) describes a number of patterns of automatic circuit-breakers with overload, overload and reverse-current, reverse-current, or no-voltage and overload attachments. These switches are provided with magnetic blow-out, and can have auxiliary trip coils fitted for remote control. Other lines of automatic and also quick-break knife switches are listed, as are also several types of open and ironclad porcelain replacement fuses. Switchboard and engine-room clocks are included in this pamphlet, which also contains illustrations of a very compact form of crane or factory switchboard enclosed in an iron case, and a petrol-electric generating set for a low-voltage country-house installation.

DISC GRINDERS.—We have received a leaflet from Messrs. Perkin & Co., Ltd. (Lord Street Engineering Works, Leeds), describing two new patterns of steel disc grinding machines for disc diameters of 12, 14, 16 and 18 in. These are practically rotary files, and can do work for which the ordinary emery machine is no use, and which is generally accomplished by milling and shaping, followed by draw-filing or scraping.

TRINIDAD LAKE ASPHALT.—Messrs. Previté & Co., of 2 Crosby Square, London, E.C., who are consignees for the Trinidad Lake Asphalt shipped to Europe, have sent us an interesting pamphlet with regard to this very useful material. The asphalt or pitch lake in Trinidad, which was originally discovered by Sir Walter Raleigh, covers an area of 127 acres, and seems to be practically inexhaustible, as, although several hundred tons may be removed in a single day the excavations are refilled in 36 hours by the natural pressure of the asphalt from below. Analyses and other particulars are given with regard to the crude material, the "Epuré" asphalt, from which the water has been removed, and the refined Trinidad bitumen, which consists of the crude or Epuré asphalt, boiled and fluxed with certain bituminous oils.

LOCAL NOTES

ACTON: *Electricity Accounts.*—The annual abstract of the accounts of the Council for the year ended March 31st, 1909, shows that although 70,597 units were sold more than last year, the total income was less by £118. This is accounted for by the discontinuation of the street lighting early in the year, the charge for which was 4d. per unit, and the increase in the number of power units sold. The average selling price per unit was 3·33d., as against 3·88d. last year. Another effect of discontinuing the electric street lighting was to increase the generation costs per unit sold, as the maximum demand on which payment was made to the Metropolitan Electric Supply Co. for the full year included the street lighting demand, which was only continued during the first six weeks of the year. The total cost to the Council of each unit sold, exclusive of loan charges, was 3·51d., against 3·48d. last year. The deficiency, after providing for the repayment of loans and interest, was £4,944, as compared with a deficiency of £2,935 in 1907-8.

BARNES: *Exhibition.*—A sub-committee has been appointed to consider the advisability of holding an electrical exhibition.

BATH: *Electricity Accounts.*—The accounts of the Electricity Department for the year to March 31st show a total revenue of £20,342, and expenditure £10,281, but after meeting capital charges there is a loss of £384, bringing the accumulated loss on the undertaking to date £1,660. The number of units sold was 1,475,811, being 401,792 units for public lighting, 20,721 units by contract, and 1,053,298 units to private consumers. The total maximum supply demanded was 1,078 kw.

BELFAST: *Tramway Centre Poles.*—At the weekly meeting of the Tramways and Electrical Committee on the 23rd inst., the manager of the tramway system, Mr. Andrew Nance, recommended the abolition of the tramway centre poles in the interests of street traffic regulations. This was referred to the electrical engineer for report.

BRAY: "*Excess Expenditure*" *Loan.*—On p. 690 of our issue of July 29th we reported that the Local Government Board had refused to sanction a loan for works executed in 1904, 1905, and 1906. In a further communication the Board now state that with regard to the excess expenditure of £1,162, accounts had not been kept while payments in respect of the works were made, and the engineer was not able, at the time of the inquiry, to say what were the exact works necessitating the extra cost. The Board further point out that when works had been already completed they could not, under such conditions, satisfactorily determine their adequacy and suitability. Moreover, items comprised in the sum in question had long since been presented in the ordinary accounts of the Council, and had passed audit, and it was not the practice of the Board to sanction loans for such items. Regarding the sum of £460 for a new switchboard, the Board had again to point out that capital sums amounting to £407 had already been sanctioned for this work, of which £200 did not appear to have been applied for the purpose for which the borrowing was sanctioned. If so, it must have been applied towards the cost of other works. The switchboard obtained for the sum of £203 was afterwards sold by the Council for £30, and a new switchboard provided. Such replacement must be regarded as a work of maintenance, for which a loan could not be sanctioned. In the circumstances, therefore, the Board were unable to alter the decision conveyed in their previous letter, which sanctioned a loan of £1,000 for procuring a gas-producing plant, disconnecting boxes, &c.

DOVER: *Light Railways.*—The Board of Trade have recently

Digitized by Google

confirmed the undermentioned Order made by the Light Railway Commissioners :—Dover, St. Margarets, and Martin Hill Light Railway Order, 1909, authorising the construction of light railways in the borough and rural district of Dover.

GLASGOW: *Electricity Accounts.*—At the meeting of the Corporation on Friday, the accounts of the Electricity Department given in our last issue were adopted. Bailie J. W. Stewart, Convener of the Electricity Committee, said that the shrinkage in revenue arose from causes which could be easily explained. It was due to a small extent to the depression which had affected every industry in the country. It was also due to the reduction of rates conceded to certain classes of consumers. Another cause was the introduction and very extensive use of metallic filament lamps which they had urged their customers in their own interests to adopt. A further cause of the shrinkage was the closing of the annual accounts eight days earlier than usual. That resulted in a sum of £3,400 of revenue not being brought into the accounts. The shrinkage of revenue had been more than counterbalanced, however, by a reduction in expenditure, amounting to about £10,000. This was due to the more favourable terms on which they had purchased fuel, and also to a considerable extent to economies effected in the consumption of coal and a material reduction in the standing charges—rents and taxes and general administration expenses. As an indication of the progress of the department, he mentioned that during the year they had added 1,232 new consumers—an increase of 7½ per cent.—439 of whom were power consumers, representing in the aggregate 5,757 h.p., which meant the closing down of some 40 to 50 boilers and chimneys, and showed that the department was a valuable auxiliary to the health of the city.

HUDDERSFIELD: *Municipal Tramways Conference.*—The Mayor, Chairman, or Deputy Chairman of the Tramways Committee, and the Tramways Manager, have been appointed to attend the annual conference of the Municipal Tramways Association, which will be held in London next month.

KINGSTOWN (DUBLIN): *Tramway Speeds.*—The Dublin United Tramways Co. have asked for the consent of the Council to an increase in the speed of the Company's "express" cars from Dublin to Dalkey in view of an application to the Board of Trade for such increase. The Dublin & South Eastern Railway Co., however, have sent a letter to the Council protesting against any increase as overriding the terms of the tramway company's Acts of Parliament, and constituting it practically a railway company. The Council have passed a resolution against the proposed increase.

LEEDS: *Tramway Receipts.*—The total receipts for the financial year to date (twenty weeks) from the municipal tramways amount to £135,512, an increase on the receipts at the corresponding date of last year of £1,548.

LONDON: *London County Council: Tramways.*—Wednesday, September 15th, has been fixed for the inauguration of the tramway service over Blackfriars Bridge. Test runs have been made during the past week.

Highgate Hill Tramways.—The County Council withdrew the service of cable tramcars on Highgate Hill on Monday night. It will be remembered that the undertaking was acquired last year from the Highgate Hill Tramways Co. with a view to the conversion of the lines to electric traction on the conduit system, and the work of conversion is now to be put in hand. The Highgate Hill cable tramway system was laid down about 25 years ago, and was the first of its kind in Europe; but although a number of other places in Great Britain, including Birmingham and Edinburgh, adopted the system, they have all been abandoned, with the exception of the excellent service in Edinburgh, which now remains the only example of cable traction in the United Kingdom. The cessation of the service on Highgate Hill was the occasion of a remarkable outburst of enthusiasm on the part of the inhabitants, people fighting to get upon the cars, and letting off fireworks, coloured lights, &c.

MANCHESTER: *Theft of Electric Lamps.*—Two men named Withers and Brocklebank were before the Manchester magistrates on Saturday on a charge of stealing tantalum lamps to the value of £9 10s., the property of Messrs. Drake & Gorham, Ltd. Mr. George Hamilton, of Messrs. Drake & Gorham, stated that about 6,000 tantalum lamps, valued at from £500 to £550, had been stolen from the firm, and in order to give the police an opportunity of tracing them, prisoners were remanded until to-day (Thursday).

PORTRUSH (IRELAND): *Condition of Tramway Track.*—Two summonses against the Giant's Causeway, Portrush, & Bush Valley Railway & Tramway Co. by Antrim County Council and the Portrush Urban District Council respectively were heard at the Portrush Petty Sessions last week. The company was summoned for allowing the tramway track to remain in a bad state of repair, inasmuch as the level of the rails was below the level of the roadway outside the track. Evidence was given by the Surveyor to the Portrush Council, and by the Engineer to the Tramway Company, whose case was that the Council had, in repairing their portion of the roadway, raised the level above that previously maintained, and that in the circumstances the company could not be bound, under their Acts of Parliament, to keep their track to the same level. It was also claimed that the proper course on the part of the local authorities was to ask the Board of Trade to send down an inspector. In the end, the magistrates dismissed the case, without prejudice, and awarded £1 costs to the company on each summons.

PORTSMOUTH: *Electric Lighting Accounts.*—The revenue from the Corporation electricity undertaking for the year to March 31st amounted to £48,631, and the expenditure to £24,442. After meeting capital charges, a balance of £3,930 remains, of which the sum of £2,000 is voted to relief of rates, £573 to insurance fund, and £1,357 is utilised as a revenue contribution to capital outlay. During the year, 3,476,730 units were sold, of which 746.823 were for public lamps, 25,693 under contract, and 2.704.209 to private consumers. Public lighting now consists of 266 large arcs, 166 flame arcs, and 463 incandescents. The total maximum demand was 2,750 kw.

ST. PETERSBURG: *Tramways.*—The *Financial News* St. Petersburg correspondent states that, contrary to the report that the offers made a few months ago to the St. Petersburg Municipality by an international syndicate regarding the reorganisation of the tramway system had been definitely rejected, it is now stated on reliable authority that the negotiations are being actively pursued. The syndicate includes besides the German General Electric Company and Messrs. Siemens & Halske, the English Westinghouse concern, and is being backed by the Deutsche Bank, together with the Société Générale. In brief, the scheme consists in the purchase from the city of all the lines, with the rolling stock and the municipal electrical works, at the price of 20,000,000 roubles; also the extension of the system, for which purpose another sum of 30,000,000 roubles would be reserved. The tramways would subsequently be worked by a company to be promoted by the syndicate, and the municipality would share in the net profits up to a maximum of 7½ per cent.

SOUTHEND: *Electricity Undertaking.*—The Engineer has reported with regard to the recent breakdown. He states that the cable was laid in 1902, and upon examination it was found that it had been roughly handled when it was laid, the insulation being stripped from the conductor in one or two places apparently during the process of drawing in. The increased revenue from the sale of electricity during the Fleet week was £90, after allowing for the normal increase and loss in transmission.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

DUDLEY.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £11,000 for the purposes of the electricity undertaking. This sum includes the cost of a storage battery, booster, and motor-generator, tenders for which have already been accepted.

ITALY.—The *Board of Trade Journal* announces that the Executive Council of the Italian State Railways have sanctioned a proposal to erect a central electric generating station at Vado, on the Ventimiglia-Savona line, at a cost of £60,000.

LONDONDERRY.—The engineer has reported that he has received an application for a large supply of power, and possibly lighting also, for the new locomotive works of the Lough Swilly Railway Co. at Pennyturn. In order to deal with this supply, it would be necessary to extend the cable system at an estimated expenditure of £889. As this extension in the meantime would only cater for this demand, he recommended that the company be asked to enter into an agreement guaranteeing to pay a minimum sum per annum for a minimum number of years for the supply. The Council have passed a resolution directing the engineer to prepare estimates of proposed capital expenditure for the above, and also the amount required to meet the demands of the increasing numbers of consumers which will be necessary in the near future, as the Council's capital powers are now exhausted.

H.M. Consul at Milan has, says the *Board of Trade Journal*, forwarded information announcing that the Executive Council of the Italian State Railways have sanctioned the proposal to erect a central electric generating station at Vado, on the Ventimiglia-Savona line, at a cost of £60,000.

Miscellaneous

AUSTRALIA.—The ratepayers of Fremantle (W.A.) have voted in favour of floating a loan of £25,714 to cover the cost of tramway extensions and additional electric lighting plant.

Tenders are invited by the Deputy Postmaster-General, Sydney, until October 6th, for the supply and delivery of 2,550 common battery telephones (2,000 wall sets, 500 table sets, and 50 party-line sets). Tender forms, specification, &c., may be obtained, and preliminary deposits paid, at the Commonwealth Offices in London, 72 Victoria Street, S.W. A copy of the specification, &c., may be seen by British firms

Digitized by Google

at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

CHINA.—According to a Consular report a scheme is on foot to construct an electric tramway from Swatow to the district city of Cheng-Hai, a distance of about 10 miles. According to the prospectus, the capital is to be 300,000 dols., in 5 dol. shares; the latter, however, are not being taken up readily. Two large rivers would require to be bridged, but otherwise the construction of the line should present no difficulties.

HUDDERSFIELD,—Tramway extensions at an estimated cost of about £14,000 are contemplated.

LONDON: *London County Council.*—Tenders are invited for the roadwork and platelaying required for the reconstruction of the tramway on Highgate Hill. The length of the route is equivalent to about 1·4 miles of single track. The contractor will be required to use the track rails with their fastenings, the slot rails and conductor rails, and the special work for the junction, cross-overs, &c., which will be provided by the Council under other contracts, but all the remaining metal work and other materials will be included in the contract. Particulars from the Chief Engineer (fee, £5, returnable), and tenders to the Clerk by September 7th.

Tenders are invited for two 500 kw. and one 150 kw. motor-generator, and high- and low-tension switchgear. (See an advertisement this week.)

Metropolitan Asylums Board.—The Board invite tenders by September 1st for the supply of stores, including electrical accessories. Particulars from the Clerk.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

ACTON.—Electric lighting is to be installed in the new public offices at an estimated cost of £450, and inter-communication telephones at a cost of £100.

AINTREE (LIVERPOOL).—Printing Works (£14,000). Builder, H. Kelly, Walton, Liverpool.

BELFAST.—Block of offices, Clyde Shipping Co. Architect, Graeme, Watt & Tullock, 7A Victoria Street, Belfast.

BIRKENHEAD.—Alterations and additions, Workhouse (£905). Architects, E. Kirby & Sons, 5 Cook Street, Liverpool.

School, Brassey Street. Builder, S. Rothwell, Birkenhead.

BOSCOMBE.—Library. Architect, C. Miles, Observer Chambers, Albert Road, Bournemouth.

Additions, Royal Hospital. Architect, G. A. B. L. Livesay, Fir Vale Chambers, Christchurch Road, Bournemouth.

DARLINGTON.—Offices. Architect, Mr. Bell, North Eastern Railway Co., York.

DERBY (WEST).—Lecture Hall (£1,500). Builder, S. Webster, Bootle.

DEWSBURY.—Nurses' Home (£6,000). Clerk to Guardians, Dewsbury.

DOVER.—School. Mr. Hawke, Borough Engineer, Dover.

EXETER.—Concert hall. Architect, J. Cricker, Queen Street, Exeter.

West of England Eye Infirmary (£3.000). Builders, Stephens, Gore Street, Exeter.

GATESHEAD.—Hall (£1,700). Architect, P. Steinlet, Camden Street, North Shields.

GLASGOW.—Laundry buildings, Messrs. Baikie & Hogg (£3,000). Architect, J. S. Hogg, 26 Frederick Street, Glasgow.

GRANTHAM.—Secondary school (£7,000). Corah & Son, builders, Loughborough.

HANLEY CASTLE.—Power station. Architect, H. Berkeley, Hanley Castle, Banbury.

LEYTON.—Tenders are invited by the Council for the electric wiring and fitting of an extension of the public offices. Particulars from the Architect, 2 Fenchurch Court, Fenchurch Street, London, E.C., and tenders to the Town Clerk by September 7th.

LONGTON.—Church and school. Vicar of St. John's, Longton.

NEWPORT (MON.).—School, Stow Hill (£19,197). Architect, C. T. Ward, Town Hall, Newport.

OXFORD.—Residence (£8,000). Architects, Tollitt & Lee, St. Aldates Street, Oxford.

Fire at the Brush Co.'s Loughborough Works.—Late on Saturday night a slight fire occurred in a coil drying room at the Loughborough works of the Brush Electrical Engineering Co., Ltd. The Loughborough Brigade quickly mastered the outbreak, with the aid of the works fire brigade. It is calculated that about £200 will cover the damage done, although the local newspaper reports gave the impression that the fire was a much more serious one.

TENDERS RECEIVED AND ACCEPTED

BURY.—At the last meeting of the Council the tender of Messrs. Clarke, Chapman & Co. was accepted for three Woodeson patent boilers for the new Chamber Hall power station.

CANADA.—It is stated that contracts for the Toronto and London sub-stations on the Government electric power transmission line have been let to Messrs. Witchall & Son (Toronto) at £7,300 and Messrs. Hyett Bros. (London) at £4,700 respectively. Tenders for eight other sub-stations will be let shortly.

DUBLIN.—An order for an electric goods elevator has been placed with Messrs. J. M'Lean & Sons, of Belfast, by the Cleansing Department.

GLASGOW.—The tender of Messrs. Allan, Arthur & Ure for wiring and fitting the Mitchell Library for electric light is recommended for acceptance at £2,799.

GOVERNMENT TENDERS.—The following tenders have been accepted for the Government Departments named:—War Office: electric cable, Callender's Cable & Construction Co., Ltd.; W. T. Henley's Telegraph Works Co., Ltd.; Hooper's Telegraph & India Rubber Works, Ltd.; India Rubber, Gutta Percha, & Telegraph Works Co., Ltd.; Johnson & Phillips, Ltd.; Siemens Bros. & Co., Ltd.; copper conductors, W. F. Dennis & Co. General Post Office: house telephone apparatus, Gent & Co., Ltd.; cable (paper core), Henley's Telegraph Works Co., Ltd.; British Insulated & Helsby Cables, Ltd.; cable, submarine, Siemens Bros. & Co., Ltd.; bell receivers, General Electric Co., Ltd.; portable telephones, British L. M. Ericsson Manufacturing Co., Ltd.; hard drawn copper wire, 800 lbs., British Insulated & Helsby Cables, Ltd.; T. Bolton & Sons; R. Johnson & Nephew, Ltd.; the Shropshire Iron Co., Ltd.; London Electric Wire Co., and Smiths, Ltd.; electric lifts at Post Office telegraph stores, Cherrywood Road, Birmingham, A. & P. Steven, 181 St. James Road, Glasgow; telephone service and equipment, extension at Ealing Telephone Exchange, the Western Electric Co.

HEREFORD.—The Corporation have accepted the tender of the Blasberg Engineering Co., of Manchester, for a cooling tower at £270.

MIDDLEWICH.—The Electrolytic Alkali Co., Ltd., have placed an order with the Key Engineering Co., Ltd., for a 500 h.p. Ehrhardt & Sehmer gas engine for driving an electric generator at their works.

SHEFFIELD.—A long discussion took place at the meeting of the Education Committee on Monday concerning tenders for the electric wiring, &c., of the training college buildings. The managers recommended the acceptance of the tender submitted by the electricity department at £155, but an amendment was moved that the tender of Messrs. Hall & Matthews, of Sheffield, at £127, should be accepted. Complaint was made by some members that although tenders were invited, it had been intended to entrust the work with the electricity department. Eventually the amendment was carried by a considerable majority, with the result that Messrs. Hall & Matthews get the contract. The matter has still to come before the Corporation, however.

COMPANIES' MEETINGS AND REPORTS

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—At the annual meeting last week, the report and accounts given in our issue for August 5th were adopted.

LANARKSHIRE TRAMWAYS CO.—At the annual meeting last week the report and accounts given in our issue for August 12th were adopted.

"Engineering Day" at the Imperial International Exhibition.—It has been decided to hold what is termed an "Engineering Day" at the Imperial International Exhibition, Shepherd's Bush, on Saturday, September 4th. Visitors will be permitted to inspect the construction and operating mechanism of the numerous examples of engineering in the amusements machinery and devices of the exhibition. The social functions will include a reception by the President (the Lord Mayor of London) and a banquet in the Garden Club. The visits of inspection will be conducted by members of the Organising Committee of the Engineering Section, and, besides the operating mechanism of the amusements, will include the sub-station for the conversion and distribution of electricity for lighting and power supply to the exhibition. Special demonstrations will be given in the Machinery Hall of various exhibits there. The following lectures will be delivered during the day in the Congress Hall:—2.45 p.m., "Water Power and Turbines," by A. Steiger; 3.30 p.m., "The Extended Uses of Electricity on Board Ship," by John McLaren; 4.15 p.m., "The Treatment of Marine Boilers on Long Voyages," by H. R. Keen; 5.30 p.m., "Large Gas Engines," by P. R. Allen; 6.30 p.m., "Snapshot Drawing for Engineers and Architects," by T. R. Ablett; 7 p.m., "The Simplest Perspective Drawing of Machinery," by C. A. Ablett. The reception by the Lord Mayor of London will be held at 5 p.m. on the Terrace of the Imperial Tower, and the banquet will take place in the Garden Club Banqueting Hall (morning dress).

Digitized by Google

MISCELLANEOUS CITY NOTES

DIRECT SPANISH TELEGRAPH CO.—An interim dividend at the rate of 4 per cent. per annum (free of tax) is announced on the ordinary shares for the half-year ended June 30th.

ASCOT DISTRICT GAS & ELECTRICITY CO.—An interim dividend of 5 per cent. per annum (5s. per share), less tax, is announced for the half-year to June 30th.

BRITISH INSULATED & HELSBY CABLES.—An interim dividend of 8 per cent. per annum is announced.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO.—The *Stock Exchange Gazette* states that the recent drop of about 12s. 6d. in the price of this company's £5 ordinary shares has been due primarily to the insistence of a private seller, who has pressed shares upon an unwilling market. Behind this lies the fact that some weeks ago the directors announced their decision not to pay an interim dividend this year on the ordinary shares, though the sum in hand would have sufficed for that purpose. It was felt, however, at the time this policy was adopted that the labour position all over the country, and in the coal trade in particular, was such as to call for great caution on the part of such a company as this in regard to the distribution of dividends, and the directors very properly decided to do nothing which would weaken their financial position. The current half-year promises, it is stated, to yield very satisfactory results, and it may be taken that for the whole of 1909 the ordinary shareholders will not receive less than 2½ per cent. by way of dividend.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 10s. to £61 per ton (last week, £60 15s. to £61 5s.).

DISSOLUTION OF PARTNERSHIP.—Messrs. D. Santoni and K. Fielder, trading as the Ely Electrical and General Agency, 24 Hatton Garden, London, have dissolved partnership.

Supply Interruption at King's Lynn.—There was an interruption in the supply from the King's Lynn electricity works early on Saturday morning due to three faults having developed on the distributing system. The most serious of these faults was at a point immediately under a leaky brick drain, and the other two were at joint boxes, and unfortunately the three faults were on different sections of the network. Supply was resumed on the remaining sections almost immediately, but part of High Street, Tower Street, and the South Gates district were still without supply on Saturday night, and on Sunday night a small portion was still disconnected. We strongly advise distributing engineers to carry out tests on their distributing networks during the next week or two, and to lose no time in unearthing and repairing incipient faults. Extremely hot weather, followed by a period of rains, has always the effect of accelerating developments of any slight faults on distributing mains.

New Secretary to G.P.O.—Having been appointed President of the National Bank of Turkey, Sir H. Babington Smith, C.B., has resigned his position of Secretary to the General Post Office, a post which he has held since 1903. Although Sir H. Babington Smith has been at the Post Office only a short time, two important matters have had to be negotiated, viz., the agreement with the National Telephone Co. concerning the transfer of their business in 1911, and the Radiotelegraphic Convention of 1906, which was the subject of a long Parliamentary inquiry in 1907. Sir H. Babington Smith is to be succeeded by Sir Matthew Nathan, G.C.M.G., at present Governor of Natal. The new secretary to the Post Office has had considerable administrative experience, having been entrusted with the administration of Sierra Leone in 1899, the Governorship of the Gold Coast in 1900, and the Governorship of Hong Kong in 1903. From the latter place he went to Natal in 1907, and will take up his new duties in London in January next. He was born in 1862.

Telegraph Traffic.—The cable between Dakar and Conakry was interrupted on the 20th inst. It had only recently been put into working order after the interruption of the 12th of May last. The cable between Trieste and Corfu has been restored, and telegraphic communication with Swakopmund has also been resumed.

Fire at Merchant Venturers' Technical College.—The meter room at the Merchant Venturers' College, Bristol, was somewhat damaged by a fire which followed an explosion due to an escape of gas on Tuesday. Fortunately, the electrical engineering laboratory, which is quite close to the meter room, escaped injury. The fire was put out with chemical extinguishers in a few minutes.

PARLIAMENTARY INTELLIGENCE

London Electric Supply Bill to be Abandoned

IN his statement to Parliament last week concerning the intentions of the Government towards the public Bills which have been introduced this session, the Prime Minister announced that the London Electric Supply Bill is to be dropped. The history of this Bill is as follows:—The London Electric Supply Act, 1908, contains provisions constituting the London County Council the purchasing authority (in lieu of the Metropolitan Borough Councils) in respect of the undertakings of nine ont of the fourteen companies authorised to supply electricity within London. These provisions were inserted in the Bill for the Act in accordance with an instruction moved by the President of the Board of Trade. An instruction for a similar purpose could not be moved on the Bill dealing with the five other companies last year, being out of order. But another instruction was passed binding the other five companies not to offer opposition to any future legislative proposals to constitute the London County Council the purchasing authority of their undertakings, and the provision giving effect to this instruction is embodied in Section 12 of the London (Westminster and Kensington) Electric Supply Companies Act, 1908. The effect of the Bill is that the London County Council will become the purchasing authority with respect to the undertakings of all the London companies, but will not be able to purchase the undertaking of one company without purchasing the undertakings of all. There was some opposition to the proposals by the City of Westminster, who stand in a somewhat peculiar position in regard to this matter, having authority to purchase the generating station of the Central Electric Supply Co., which is outside Westminster. However, no harm is done by the abandonment of the Bill this session, as none of the companies' undertakings are purchasable until 1931.

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL.—It is satisfactory to note, from the statement of the Prime Minister referred to above, that the Government intend to pass the Electric Lighting Acts (Amendment) Bill.,

The Bill was read a third time in the House of Commons on Friday. The following addition has been made to Clause 6, "Supply to premises outside area of supply in certain cases":—(4) Nothing in this section shall enable the Board of Trade, without the consent of the undertakers within whose area of supply the premises are situate, to give such permission as aforesaid to any undertakers where the last-mentioned undertakers are by any Act of Parliament specifically prohibited from supplying electricity within the area of the first-mentioned undertakers." This apparently aims at preventing the electric power companies from evading the terms of their Acts of Parliament by endeavouring to obtain the Board of Trade's consent to supply in districts excluded from their operations.

On the motion of Mr. H. J. Tennant (Board of Trade), Clause 24 (for the protection of County Councils) was struck out of the Bill. There were a number of amendments to the clause with the object of granting similar protection to railway companies, but the Board of Trade regarded this as extending the scope of the clause too much, and preferred to withdraw the whole clause.

The protection given in Clause 25 to gas undertakings is now extended to water undertakings, and the definition of "undertakers" has been made to read "any local authority, company, or person authorised to supply electricity to whom the Electric Lighting Acts apply."

It now remains to see what attitude the House of Lords will take up in regard to the various amendments in the Bill, particularly that relating to the wiring of premises and the hiring-out of fittings, &c., by local authorities.

TELEGRAPH (ARBITRATION) BILL.—This Bill will be passed this session if it is not opposed. It refers any difference between the Postmaster-General and any body or person under the Telegraph Acts, &c., to the arbitration of the Railway and Canal Commissioners, if the parties so agree.

The Cornwall Colliery Accident.—The inquest on the bodies of O. David and D. Thomas, miners employed in the Cribbwr Fawr Colliery, Pyle, who, as stated in our issue of last week, were killed by electric shock on August 12th, was concluded on Thursday last. According to the *Western Mail*, David gripped an armoured cable and received a fatal shock; he was dragged away, but artificial respiration failed. The other miner, D. Thomas, was found dead by the cable soon after. At the inquest, the colliery electrician stated that a kink had been caused in the cable by an accident with a tram on August 5th, and indications had been given of a leak between the cores and the armouring. The armouring was earthed, and had been cut and pressed back near the kink as a further precaution, and the tests had proved satisfactory. The accident was, he thought, due to an insufficient earth. Mr. Nelson, H.M. Electrical Inspector of Mines, supported this view, and recommended that a more efficient earth connection should be made, and more delicate tests carried out periodically. He did not consider the colliery managers had been well advised electrically. A verdict of accidental death was returned.

ELECTRICITY AT THE NANCY EXHIBITION

THE town of Nancy is a centre of considerable importance in the industrial district in the east of France, and it is only natural that the International Exhibition being held there this summer should embody features of electrical interest. The exhibition, which is described from an engineering point of view in *Le Génie Civil*, is held in the Parc Sainte Marie, and access to the various parts may be had by a miniature railway, with complete model "Atlantic type" steam locomotives, about 3 ft. in height. One of the largest of the many exhibition buildings is the *Palais des Arts Libéraux*, but the objects of electrical interest therein appear to be confined to an elaborate model shown by the municipality of Nancy of the river port of Malzèville, showing the electric cranes for unloading cargoes, especially of stone and sand, and electric locomotives for mineral trains. The educational section includes an exhibit which gives plans and details of the Electrotechnical Institute of Nancy, and radiographic apparatus is shown by certain hospitals.

The section of the Exhibition devoted to transport, navigation, &c., is largely devoted to steam railway rolling stock and material, including an exhibit of the London and North-Western Railway, but electric traction is only represented by an exhibit relating to the railways of the Bernese Alps, which includes photographs of the Lötchberg tunnel works, and drawings of the single-phase two-motor locomotives which are to be used on this line. The textile section contains a good deal of electrically-driven spinning and weaving machinery, including an exhibit by Messrs. Dobson & Barlow, of Bolton, of spinning frames driven on the Brown Boveri varying-speed single-phase system, with commutation motors, as described in ELECTRICAL ENGINEERING in connection with last year's Manchester Exhibition (Vol. IV., Manchester Exhibition Supplement, p. 26). There is also a very complete collection of textile machinery shown by the Société Alsacienne de Construction Mecaniques, which firm also occupy a prominent position in the Palais de l'Electricité. Their exhibit includes:—An electric mining locomotive, 23½ in. gauge, for a draw-bar pull of 2,560 lbs., as used in the Grand Combe mines (Gard); special three-phase motors for textile machinery; an electric locomotive axle with two 9-h.p. motors, and a "Stone" 24-volt train-lighting dynamo (such as is largely used on French and English railways and by the International Sleeping Car Co.), for supplying 30 lamps.

Reference has already been made in our columns to the exhibit of the Compagnie Générale Electrique de Nancy in this building, which includes a variety of plant and apparatus, including a mine haulage plant, fully enclosed mining motors, electrically-driven pumps, fans, and compressors. There is also a large display of continuous- and alternating-current motors, rotary converters, transformers, &c., including a 140,000-volt testing transformer. Attention should be drawn to an electric capstan, a self-contained electric hoist, and a special exhibit of continuous-current traction motors with commutating poles. The smaller apparatus shown by this firm includes small transformers and miniature converters for low voltage metal filament lamps, measuring instrument transformers, electric drills, ignition accumulator charging sets, arc lamps, switchgear, and a display of accumulators made by the company at their works at Frouard. Other exhibitors in this section include Les Etablissments F. Henrion, also of Nancy, which shows motors, converters, and other apparatus, and La Compagnie Electromécanique, of Le Bourget, near Paris.

The Palace of Mining and Métallurgie also contains the generating station from which the greater part of the exhibition is supplied. The exhibit here of the firm of Dujardin, of Lille, comprises a generating set with a Henrion dynamo, driven by two-cylinder cross-compound horizontal engine, a 550-kw. turbo-generator, and a model of an electric colliery winding plant. There is also shown a group of three Thomson-Houston 100-kw. dynamos rope driven by a 600-h.p. tandem compound "Beya" engine, by Berger André & Co., of Thann (Alsace). The Compagnie Générale Electrique also exhibit here. The most interesting item in their display is a 750 h.p. continuous-current generator, running at 2,000 r.p.m., driven by an "Elektra" turbine. The design of the generator, which is for 250 volts, presents the features of commutating poles as well as compensating windings, and a special patent brushgear. A turbo-alternator for 250 k.v.a. at 3,000 r.p.m., with two-pole rotor, and single excitation coil, and a 10-h.p. petrol-driven generating set are also shown. The Société Alsacienne de Constructions Mécaniques have also an extensive display in this section, including a 650-kw. 5,000-volt three-phase turbo-alternator running at 3,000 r.p.m., and a 350kw. 250-volt continuous current generator driven at 125 r.p.m. by a Stumpf engine exhausting into a Westinghouse-Leblanc condenser. The firm also show a 450-kw. 50,000/180-volt transformer, a six-phase 350-kw. rotary converter, and the complete field magnet system of a 1,900-kw. 550-volt 50-cycle slow-speed alternator over 26 ft. in diameter. This part of the building is served by a 10-ton electric traveller by the Société d'Appareils de Levage, of Paris. Among the metallurgical exhibits proper may be noticed a cast steel carcase for a 1,000-kw. dynamo weighing 16 tons, shown by the Longwy Steel Works. Other exhibits in the mining section include two generating sets driven by engines with Lentz valves by the firm of Lang, of Mannheim, and electrically-driven pumps of the Société de la Meuse (Liége). The Creusot stand is interesting on account of the display of manganese steel tramway special work, and a short length of construction demonstrating a side slot conduit system, with special combined slot and track rail points. A turbo-generator is also shown on this stand. Electrically-driven pumps are also shown by the Worthington Co. and Messrs. Sulzer Brothers.

Electrical machinery is also shown to some extent in the "Batiment des Moteurs et Machines Outils," where there are also a pair of the well-known semi-portable superheated steam "locomobiles" of Messrs. R. Wolf & Co., of Magdeburg, and Messrs. Ehrhardt & Sehmer, of Saarbrucken, exhibit pumping machinery; small electrically-driven pumps are also shown by Messrs. Japy Brothers, of Beaucourt, who have on view amongst other plant a compact 8-h.p. oil engine generating set. The Babcock Wilcox Co., of Paris, show a model of their boilers as erected at the St. Denis Station, and several other firms have displays relating to steam plant. A special feature of the exhibition of not strictly electrical interest is the aeronautical section, which includes the large dirigible balloon, Ville de Nancy, which made the voyage from Paris, and several aeroplanes and models.

Tax on Electric Lamps in Germany.—The amounts of the tax on electric lamps, arc lamp carbons, and other illuminating apparatus, which will be imposed on such goods, both manufactured in Germany and imported from other countries, on and after October 1st next, were given in ELECTRICAL ENGINEERING of July 29th, p. 693. The following additional particulars as to the administration of the tax are given in the *Board of Trade Journal*. The tax is to be paid by the manufacturer by affixing tax stamps to the packages before the completely packed articles are removed from the factory, &c., where they are made. In the case of imported articles, the tax is to be paid by the importer at the time of clearance through the Customs house. Articles and materials for lighting which are liable to taxation under the present law may not be removed from the place of manufacture in Germany or imported into Germany from foreign countries, otherwise than in completely closed packages which cannot be opened without leaving recognisable traces. The kind of packing and the permissible size of each package is to be prescribed by the Bundesrat. Particulars of the contents are to be marked on each package, *i.e.*, in the case of electric incandescent lamps, burners therefor, and mercury-vapour and similar lamps, the number and watt-consumption, in the case of mantles, the number, and in the case of carbons for arc lamps, the net weight. In addition, each package must bear an indication of the tariff class under which it is liable to duty, and the designation of the contents (trade mark).

Central Battery Telephone Equipment at Bromley.—On Saturday, the 14th inst., at 2 p.m., the National Telephone Company transferred the subscribers connected to its Bromley exchange to a central battery equipment installed in new premises, which have been specially designed, in Church Road, Bromley. The new exchange equipment has been manufactured and installed by the Western Electric Co., of North Woolwich, and is of the No. 1 common battery type, consisting of ten subscribers' positions, giving accommodation for 1,500 lines, and three incoming junction positions. The ultimate capacity of the switchboard is 6,000 lines, and the equipment is of similar design to the equipments installed at the company's Altrincham, Birmingham Midland, and Hillhead exchanges.

Patent Agreement between Germany and the United States.—Commenting on the new reciprocal patent treaty between Germany and the United States, the *Electrical World* points out that American inventors will greatly benefit from the removal of the German restriction under which their patents have hitherto been forfeited if not actually worked in Germany within three years. Under the new treaty an invention reduced to practice in *either* country is fully protected in both countries when patented in both Germany and the United States. The agreement is immediately effective, and is to remain in force until the expiration of twelve months following a notice of termination by either Germany or the United States. It is said that at the Congress for the Protection of Industrial Property, which will meet in Washington in 1910, about thirty nations will be represented. An endeavour will be made to harmonise the laws of the various nations relating to the protection of patents and trade-marks.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 19th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

15,802/08. **Eliminating Temperature Errors in Meters.** G. Hookham. The temperature error in mercury and other meters is compensated for by arranging a shunt-resistance wire in a chamber in such a way that when the temperature increases, mercury rises in the chamber and alters the effective length of the wire. The wire is provided with amalgamated kinks at intervals to make good contact with the mercury, and the movement of the mercury column is effected by the expansion of oil. Three claims, three figures.

22,577/08. **Petrol-Electric Driving Gear.** G. F. O. Pollet. The armature of a continuous-current machine is coupled to the shaft of the petrol motor, and the field system is mounted in ball bearings, but held stationary when it is desired to transmit power. The relative speed of both parts remains constant. The field system and the gear casing are provided with brakes which are worked by a solenoid in the motor shunt field circuit, and are so arranged that when one brake is "on," the other is "off." A governor, which rotates only when the gear case rotates, opens the inlet valve of the engine in accordance with the power required. Four claims, two figures.

22,964/08. **Lamp Shade Gallery.** S. Falk (Falk, Stadelmann & Co.). Pins are pressed upon the shade rim by spiral springs contained in the cylinders secured to the gallery, through which they slide. Each pin has a tongue parallel with the pin itself, which normally passes through a hole in the gallery adjacent to the pin, but which, by giving the pin a turn, bears on the gallery and holds the pin outwards while the shade is being inserted. Two claims, two figures.

25,007/08. **Insulation of Wire.** P. MacGahan. The copper bar to be drawn into wire is given a coating of aluminium before rolling. The wire drawn from this has thus a very thin coating of aluminium, and if it is passed through an electrolytic bath containing ammonium borate or other suitable solution, a thin film of aluminium oxide (which is a good insulator) will be formed. The metals need not necessarily be copper and aluminium. One claim, one figure.

27,523/08. **Incandescent Lamp Fitting.** C. W. Frauenlob. The lamps are supported just below an opaque reflector in the shape of an inverted cone, and a wide-mouthed, shallow, transparent bowl is suspended by chains or wires on a level with the lamps. The angle of the upper reflector is such that the upward rays from the lamps are reflected slightly downwards. One claim, one figure.

5,821/09. **Metal Filaments.** British Thomson-Houston Co., Ltd. (*General Electric Co., U.S.A.*). The higher oxides of the refractory metals are reduced to the lower oxides, by heating them to a temperature of 800° C. in graphite crucibles enclosed in carbon packing. Thus, if the yellow tungsten oxide WO_3 is treated in this way, the air produces CO by action on the carbon packing, and this reduces the WO_3 to WO_2, forming CO_2. The CO_2 and the carbon packing react to form CO, which continues the reduction of the WO_3. The brown oxide WO_2 produced is made up into a squirting mixture. Two claims, one figure.

6,850/09. **Driving of Machine Tools.** P. M. Justice (*La Société Anonyme Electricité Electromécanique*). A friction coupling with friction blocks carried on spring arms adjusted by screws, is interposed between the motor and the machine, so that if the load is excessive the blocks slip and prevent overloading of the motor or breaking of the drill or other tool. Three claims, two figures.

8,194/09. **Induction Furnaces.** The Grondal Kjellin Co., Ltd., and J. Härdén. The lining of the melting chamber contains a high proportion of graphite, so that on switching on the primary, a current is induced in the lining strong enough to heat it to such a degree that the charge is melted into a continuous ring of molten metal, which then becomes the secondary circuit. By this means the necessity for metal rings or a supply of molten metal for starting, is avoided. The furnace is started with only a portion of the primary winding in circuit, the remaining portion being switched in automatically when the charge is melted. For treating metals for which a high percentage of graphite in the lining is unsuitable, the lining is given a coating of magnesite. Five claims, one figure.

Opposition to Grant of Patents

28,354/07. **Jointing Wires and Tubes.** British Insulated & Helsby Cables, Ltd., and D. B. Saunderson. In spite of opposition, a grant on this application has been allowed. The patent relates to a process for welding wires, electric cables, and tubes by non-electrical means, and was abstracted in Electrical Engineering, January 28th, 1909, page 94.

3,626/08. **Motor-Generator.** Crompton & Co., Ltd., J. C. Macfarlane, and H. Burge. The opposition to the grant of this patent, which relates to a motor-generator set for supplying constant current at a varying pressure, has been unsuccessful, and the patent has been granted. An abstract of the specification was given in Electrical Engineering, March 11th, 1909, page 247.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Thomson [Suspension device] 18,408/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Parsons, Greaves, and Hemsted [Conductors] 16,620/08; Demuth [Machines for insulating wires] 1,125/09; Owen [Asbestos fibre insulating material] 7,530/09; Greiner [Detection of faulty H.-T. insulators] 14,952/09.

Dynamos, Motors, and Transformers: Parsons and Law [Machines] 16,704/08 and 11,822/09; Parsons [Commutators] 16,911/08; Trier [Generators] 21,813/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Motor-generator sets] 5,209/09; Siemens Bros. Dynamo Works, Broadhead, and Wall [Train-lighting systems] 5,544/09.

Electrochemistry: Otto [Production of ozone] 16,542/08.

Instruments and Meters: Edwards and Berrington [Pen for recording instruments] 20,251/08.

Switchgear, Fuses, and Fittings: Boult (*Electrical Manufacturing Co.*) [Circuit-breakers] 17,748/08; Veritys, Ltd., and Pipkin [Quick make and break switch] 20,646/08; Horrocks and Lett [Ironclad switches] 22,768/08; Leitner [Apparatus for reversing connections of dynamos] 27,685/08.

Telephony and Telegraphy: Schiessler, 16,183/08; O'Neil [Telegraphy] 16,462/08; Marconi, and Marconi's Wireless Telegraph Co. [Wireless telegraphy] 16,546/08; Marks (*Burlingame Telegraphing Typewriter Co.*) [Printing telegraphs] 18,518/08; Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*) [Telephone exchanges] 13,750/09 and 13,919/09.

Traction: Francis [Automatic brakes] 12,165/08; Twinberrow and McKerrow [Brakes] 23,524/08; Shade [Brakes] 26,047/08; Lake (*European Brake Shoe Co.*) [Brake shoes] 28,344/08.

Miscellaneous: Ullrich [Magnetic separation of ores] 14,082/08; Gin [Thread singeing apparatus] 22,917/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: Allgemeine Elektricitäts-Ges. [Control of polyphase motors] 17,758/09; Electric Reductor Co. [Closed-circuit transformers] 17,761/09.

Electric Ignition: Mueller [High-tension magnetos] 17,663/09.

Electrometallurgy: Aktiebolaget Elektrometall [Electric furnaces] 17,342/09.

Instruments and Meters: Compagnie pour la Fabrication des Compteurs et Material d'Usines a Gaz [Meters indicating maximum demand] 17,138/09.

Telephony and Telegraphy: Fessenden [Signalling] 14,826/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: J. Rosemeyer [Globe construction for enclosed lamps] 9,429/99.

Electric Ignition: O. von Morstein [Control of gas lamps] 9,402/96.

Electrometallurgy and Electrochemistry: J. Swinburne [Electrolytic treatment of sulphide ores] 10,829-9A/97; R. D. Sanders [Electrolytic deposition of metals] 9,011/01; J. Hogarth [Treatment of grain] 9,039/01; Siemens Brothers & Co. and W. F. Eichenauer [Sealing dry cells] 10,559/04.

Incandescent Lamps: Improved Electric Glow Lamp Syndicate, Ltd. (*C. Schwabe*) [Silvering bulbs] 9,656/96.

Switchgear, &c.: W. F. Jones [Motor-starter] 8,315/00; T. Sutcliffe [Ceiling roses] 10,044/04.

Traction: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Air brakes] 10,021/04.

Miscellaneous: N. Jacobsen [Alarm signal system] 10,376/04; T. E. Adams [Electrically-driven percussive drills] 10,571/04.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** *weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

We review the Electric Lighting Acts (Amendment) Bill in the final form in which it has left the House of Commons. Clause 16, which gives power to local authorities to undertake wiring, &c., has been deleted. (Page 771.)

An order has been issued exempting certain premises in which electricity is only used for lighting from the Home Office Regulations for electrical installations in factories. (Page 772.)

An electric geyser comprising a porcelain chamber with a number of platinum diaphragms between which the water circulates has been placed on the market. The current passes between the diaphragms through the water itself, heating it in its passage. The methods of preventing shock to the user and of making the leakage current negligible are especially interesting. (Page 772.)

In a Paper read before the American Institute of Electrical Engineers Mr. J. B. Taylor describes the effect of the introduction of a direct current into the windings of the transformers of an A.-C. system, as may result from leakage from a neighbouring D.-C. traction system or in consequence of the out-of-balance current of a three-wire system supplied from a rotary converter. He states that the increase in the iron losses due to working the magnetic cycle round a point of high density is slight, which is contrary to the conclusion of Dr. Coales, given in a recent Paper read before the Birmingham section of the Institution of Electrical Engineers. (Page 773.)

A rectifier particularly adapted to the charging of ignition batteries off A.-C. supply mains has been introduced. It comprises a set of vibrating contacts which connect the load circuit alternately to two portions of the secondary winding of a transformer, the connection being so made every half-period that a succession of rectified half-waves are delivered into the circuit. An efficiency of 90 per cent. is claimed. (Page 773.)

In a column devoted to wireless telegraph matters, the most important item is the suggestion that all ships should be compulsorily fitted with wireless telegraph apparatus. The failure of the wireless telegraph apparatus in the recent cavalry manœuvres is also referred to. (Page 774.)

Digitized by Google

THE annual report issued by the chief engineer to the British Engine, Boiler, and Electrical Insurance Co. gives some interesting descriptions of typical causes of breakdowns in electric motors. The nature of the accidents caused by dirt and neglect are particularly emphasised, and remarks are also made with regard to some errors in construction which occur too frequently. (Page 775.)

IN connection with the inauguration of the new route between London and New York by the *Mauretania* on Monday last, we give some particulars of the electrical equipment of Fishguard Harbour, which comprises electric cranes, capstans, and travelling platform traversers, besides the electric lighting of the harbour works and station buildings. (Page 776.)

A COMMITTEE is to be appointed to revise the Home Office Regulations relating to electrical installations in coal mines. The decision of the Home Secretary to appoint this Committee has been arrived at in view of the evidence in connection with the recent explosion at the West Stanley pit. We publish particulars of the cause of the accident which occurred at the Cribbwr Fawr Colliery on August 12th. (Page 777.)

IN his annual report upon the electrical industry in Germany, Sir Francis Oppenheimer, H.M. Consul at Frankfort, speaks of the deleterious effect of the threatened danger of the introduction of a tax on electricity. (Page 777.)

THE second pair of twin tube tunnels under the Hudson River, belonging to the Hudson & Manhattan Railroad Co., of New York, were opened to the public service last month. The terminus station occupies three floors below ground, on the lowest of which is a sub-station containing two 1,500-kw. rotary converters for the traction load, and four 750-kw. machines for the lighting load. (Page 778.)

THE Aberdeen Tramways Co. have repudiated the recent award of the arbitrator on the question of the price to be paid to the Corporation for electrical energy. —Tangential suspension is to be dispensed with on the Haslingden tramways.—Manchester tramway receipts for the current financial year to date are less by £3,800 than last year.—After meeting all capital charges, South Shields Corporation tramway accounts for last year show a profit of £423. Complaint is made at the high charge for electrical energy.—The date for the opening of the widened Blackfriars Bridge has been changed to September 14th.—Two men have been sentenced for stealing tantalum lamps from Messrs. Drake & Gorham, Ltd., at Manchester. (Page 779.)

MANCHESTER Corporation propose to borrow £50,000 for mains extensions, and Burslem Corporation £7,535 for generating machinery. A common battery switchboard is required by the Australian Postmaster-General. Wigan Corporation have accepted a tender for a Curtis turbine, and also switchgear, &c. (Pages 780–1.)

THE accounts of the Underground Electric Railways Co., of London, for the half-year to June 30th, show a large deficit.—Proposals have been made for converting the Isle of Wight Central Railways to electric traction. (Page 781.)

DR. ALEXANDER RUSSELL has been appointed successor to the late Mr. H. E. Harrison as Principal of Faraday House. (Page 782.)

WE publish brief abstracts of Sir Joseph J. Thomson's Presidential Address to the British Association at Winnipeg last week, and of some of the addresses of the sectional presidents. A Paper was read by Prof. W. M. Thornton and Mr. O. J. Williams, in which the stresses in the dielectric of three-core cables were deduced by the Hele-Shaw stream-line method. An abstract of this, with illustrations, is given, and also abstracts of two Papers on standard cells. (Pages 783–786.)

A MAXIMUM demand attachment for Aron meters for indicating the maximum of the average demands over any predetermined interval of time has been introduced. The pointer indicating the demand is geared to the counting train of the meter for the period arranged, and is thus carried round an angle proportional to the average demand during that period. The pointer is left in this position, but its wheel is released and then again geared to the train for the same period. If the second average demand is greater, the pointer is carried round farther; if less or the same, it is not touched. (Page 787.)

AMONG the specifications published by the Patent Office on Thursday last was one by C. A. Parsons, J. H. Greaves, and A. R. Hemsted for a method of manufacturing flat stranded conductors for winding armatures. It consists in first making a wire tube and then flattening it. The use of shaped conductors only partially embedded in dove-tail shaped slots, so that the self-induction of the winding is reduced to a minimum, is protected by C. A. Parsons and A. H. Law, and a construction of iron-clad switch-case which cannot be even partially opened when the switch is closed is patented by F. S. Horrocks and T. C. Lett. A knife-switch with a spring arrangement to give both quick make and break is described in a specification by Veritys, Ltd., and W. G. Pipkin, and the British Thomson-Houston Co. have patented a new motor generator set for supplying constant current at varying potential. The British Coalite Co., Ltd., have applied for the amendment of the specification of a patent granted to T. Parker for an electrolytic process for the production of sodium or potassium chlorate. (Page 788.)

ELECTRIC LIGHTING ACTS (AMENDMENT) BILL

The House Wiring Clause Dropped

THE somewhat inconsistent legislation which characterises the electrical industry is at length brought to something approaching uniformity by the third reading of the Electric Lighting Acts (Amendment) Bill in the House of Commons, for the passing of the Commons amendments in the House of Lords and the Royal Assent to the measure will now follow as mere matters of form. Owing to the inability of sections of the industry to come to an agreement upon certain points, the Government found itself faced with the discussion of a highly controversial matter at the end of an exceptionally long session, with the possibility of subsequent difficulties with the House of Lords which would have endangered the whole of the Bill.

The clause which endangered the passing of the Bill, and about which the greatest interest centred, has been dropped. This was Clause 16, which proposed to give powers to municipal authorities to wire premises, provide electrical fittings, &c. The law in respect to this is in a very unsatisfactory state; the Electric Lighting Acts themselves give no power to the Local Authority to do house wiring, but a considerable number of local authorities have obtained such powers by private Acts of Parliament, while one or two have power to do wiring through firms of contractors, the modification usually having been made to meet local opposition before the Bills were submitted to Parliament. The London Borough Councils were authorised to do house wiring work by clauses in a General Powers Act, promoted by the London County Council in 1906. In the early days the electrical contractors, unorganised as they were, hardly realised what was being done in this direction; the clauses in question were frequently hidden away in bulky municipal General Powers Bills, dealing with a multitude of matters (the so-called "Omnibus" Bills), and it needed a systematic and keen search of the Bills at the commencement of each session to bring them to light. Consequently a number of municipalities

Digitized by Google

secured their powers unopposed. Opposition was offered to the L.C.C. General Powers Act of 1906, but without success. Since then, however, the Contractors' Association has been placed upon a different footing, and an active campaign is being carried on throughout the country against the granting of wiring powers to municipalities.

Evidence of this is given in the result of the present year's Parliamentary work. In the case of Bills promoted by Greenock, Watford, Oldham, Mountain Ash, and Heywood Corporations, the wiring clauses have either been struck out or withdrawn, in each case owing to opposition of the National Electrical Contractors' Association, whilst in the case of the Shrewsbury Corporation Bill, the wiring clause appears with the proviso that the work may only be carried out through a contractor. A Bill by the Cardiff Corporation, which contains similar clauses, has yet to come before the House of Lords, when the Association will oppose, although the clauses have been amended from their original form.

The Electric Lighting Acts (Amendment) Bill, in the form introduced into the House of Lords this session, would have given a general power to municipalities throughout the country to undertake the wiring of premises and the provision of fittings, &c.; but on the motion of Lord Avebury, at the instance of the National Electrical Contractors' Association, an addition was made to the clause that the work could only be carried out through a contractor. The municipalities succeeded in obtaining the deletion of this proviso when the Bill was before a Standing Committee of the House of Commons, and a deadlock ensued, as the municipalities, at any rate, were disinclined to give way on the principle, although the majority of municipal electrical engineers prefer to hand the work over to contractors. There are other matters in the Bill of wider importance and application than the house-wiring clause, and, therefore, in order to secure its being passed without opposition, the Board of Trade decided to withdraw the wiring clause from the Bill altogether. This is the only course which would be in any degree acceptable to both parties, for it means that the present position is maintained, and that each municipality will have to apply to Parliament separately for wiring powers, while the National Electrical Contractors' Association will have a *locus standi* to oppose.

Another clause which was withdrawn, although it is not of such importance as the wiring clause, is one which gave power to county councils to alter temporarily the position of electric mains, &c., carried over county bridges during repairs, rebuilding, &c. Sir Frederick Banbury moved that similar powers be granted to railway companies in the case of bridges maintained by them, but the Board of Trade, with the knowledge that the House of Lords objected, did not accept the amendment, and the deletion of the clause from the Bill was agreed to.

A new clause was added to the Bill on third reading, prohibiting the establishment of non-statutory electric supply undertakings. In other words, in a district where there is already an authorised distributor, no other local authority, company, or person may undertake the business of electric supply without statutory powers. The clause, however, will not apply in the case of supply by one man to his neighbours, as a matter of convenience, as the business of the individual giving the supply "is not primarily that of the supply of electrical energy to consumers." The origin of the clause is due to an agitation by Scottish local authorities owning electricity works against a proposal to establish the North British Electric Power Syndicate, whose mains were to be laid alongside the lines of various railway companies. Thus works could be supplied with electric power without statutory authority or the consent of existing authorised distributors. The Edinburgh Corporation took the matter up very seriously, and a deputation of Scottish authorities waited upon the Board of Trade, who, at the time, thought the position not so serious as had been contemplated. The clause was accepted at the eleventh hour, without discussion.

Some other amendments were made on third reading. The following addition has been made to Clause 6, "Supply to premises outside area of supply in certain cases":—"(4) Nothing in this section shall enable the Board of Trade, without the consent of the undertakers within whose area of supply the premises are situate, to give such permission as aforesaid to any undertakers where the last-mentioned undertakers are by any Act of Parliament specifically prohibited from supplying electricity within the area of the first-mentioned undertakers." This apparently aims at preventing the electric power companies from evading the terms of their Acts of Parliament by endeavouring to obtain the Board of Trade's consent to supply in districts excluded from their operations.

The protection given in Clause 25 to gas undertakings is now extended to water undertakings, and the definition of "undertakers" has been made to read "any local authority, company, or person authorised to supply electricity to whom the Electric Lighting Acts apply."

We dealt at some length with the clauses relating to meters in ELECTRICAL ENGINEERING of July 22nd. These are adopted, as are all the other clauses summarised in our issue of July 22nd (p. 672), with the exception of those which we have indicated above.

In general, the main result of the passing of the Bill will be the removal of certain difficulties and anomalies which have been experienced in the working of the Electric Lighting Acts, the generalisation of provisions usually inserted in local acts with a view to improving the position of electricity supply undertakers, and the simplification of procedure.

CORRESPONDENCE

STREET ELECTRIC LIGHTING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In view of the report presented by the deputation of the Streets Committee of the Corporation of London who recently visited the Continent, we were surprised to find on our visit to Berlin a few days ago that the principal streets—such as Unter-den-Linden, Friedrichstrasse, Leipzigerstrasse, Potsdamerstrasse, &c., corresponding to Regent Street, Oxford Street, Piccadilly, Strand, &c.—were lighted by arc lamps (white flame), mostly suspended in the centre of the streets on span wires fixed to the buildings, and with automatic contact lowering gear with arrangements for drawing to the side for trimming.

Only the less important streets were lighted by gas; and, judging from the effect, we can only imagine that the Berlin City Fathers, being progressive (as shown by the beauty of their charming city), are not likely to take the retrograde step of putting in more gas lighting than they can possibly help.

With regard to the recommendation that all lamps (both gas and electric) shall be on lowering gear, we believe we pointed out to you some months ago that our lowering gear is equally applicable to gas as to electric light, by the substitution of a gas connection for the usual electrical coupling, and there is no difficulty to us in dealing with this problem either for swan-neck poles, centrally-hung carriers, or cross-street suspension gear.

Yours faithfully,

P.Pro THE LONDON ELECTRIC FIRM.
(*G. A. Hughes.*)

London, August 31st, 1909.

Electric Traction in Germany.—According to the *Elektrotechnischer Anzeiger*, electric traction is to be adopted for the main line sections, Lauban-Görlitz, Görlitz—Kohlfurt, Kohlfurt—Lauban, and Lauban—Marklissa, in Silesia, the work of equipment to be completed by May, 1910. Electric power is to be taken from the Queis-talsperre Works, near Marklissa. Four coaches, each with a seating capacity for 130 passengers, are to be run on each section at frequent intervals.

The Hackney Institute.—We have received a syllabus of the classes to be held at this institute in the coming session. The institute consists of the Hackney Technical Institute, Dalston Lane, N.E., and the Sir John Cass' Hackney Institute, Cassland Road, N.E., and was established in accordance with a scheme prepared by the Charity Commissioners to provide evening classes for technical and general educational intruction in the district. Classes in engineering, science, art, music, &c., are held at the Hackney Technical Institute, and the other institute is devoted to practical trade classes. The syllabus includes special preparation courses for the Board of Trade examinations in science and engineering, the Whitworth Scholarships and Exhibitions, the City of Guilds of London Institute examinations, and the examinations of the Institution of Civil Engineers, the Patent Office, and other institutions. Courses for the London University B.Sc. degrees in both science and engineering are also arranged. The only day classes are those held in the art and music departments. Full particulars of the lectures and laboratory work in all departments is given in the syllabus, together with a series of reproductions from photographs of the various laboratories and workshops.

THE HOME OFFICE FACTORY REGULATIONS

IN the Regulations issued by the Home Office for electrical installations in factories and workshops, it is stated that the Home Secretary may exempt any class of premises from being bound to observe these regulations in which the conditions are such as "adequately to prevent danger." An order has now been issued exempting rooms, other than electrical stations, in which the following special conditions are observed:

no electrical energy is used except at low pressure, nor for any purpose other than lighting by means of incandescent lamps; and
the floor is of wood or otherwise insulating; and
there is no machinery or other earthed metal with which a person handling any non-earthed lamp fittings or any portable lamp is liable to be in contact; and
no process rendering the floor wet is carried on; and
no live conductor is normally exposed so that it may be touched.

The Order is not very happily worded, for if taken literally it would exclude from its benefits factories in which electricity is only used for lighting if the wiring is on the ordinary earthed metal conduit system whenever the lamp fittings are not earthed, or portable lamps are used. It also raises the question as to whether the customary use of soap and water for scrubbing the floors contributes a "process rendering the floor wet."

AN ELECTRIC GEYSER

A NEW development in electrical heating apparatus has been placed on the market by Messrs. John C. Fuller & Son, of Woodland Works, Wick Lane, Bow, London, E. This consists of an electric geyser or water-heater, in which the water is heated to the full temperature required in its passage through the apparatus. The electrical energy supplied is converted into heat energy in the water itself, which is used as the resistance path for the current, and so the only loss in the apparatus is that due to radiation. This last is very small indeed, so that a high efficiency is obtained.

Fig. 2 is a rough sketch illustrating the principle of the apparatus, which consists of a porcelain cylinder *A*, with porcelain

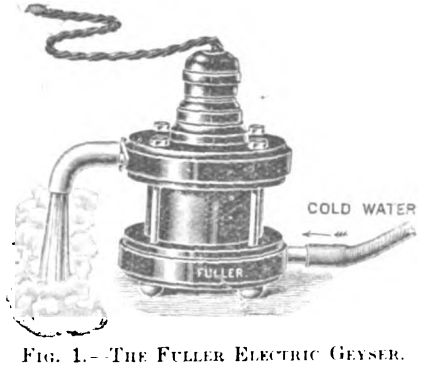

FIG. 1.—THE FULLER ELECTRIC GEYSER.

caps *B* screwed in at each end, the intermediate space being filled up with a series of very thin platinum diaphragms *C* separated by porcelain rings *D*. As indicated in the sketch, the water enters at the bottom and flows upwards between the diaphragms through circular apertures cut in them on alternate sides of the centre so as to give a zig zag flow. Alternate diaphragms are connected together, and the two sets of diaphragms are connected to the supply circuit. Current flows between opposite plates when water is flowing through the apparatus, and thus heats the water. A certain amount of electrolysis takes place when continuous current is used, but the oxygen evolved is dissolved in the water and purifies it, while the hydrogen is liberated into the atmosphere. When water is passed through slowly and emitted at a high temperature, very little gas is evolved. As shown in the sketch, the inner cylinder is clamped between two thick earthenware end-plates by brass rods passing through both these, and outside the cylinder. The inner edges of the cylinder bear against rubber rings *F* let into grooves in the end plates to make the apparatus water-tight. An outer earthenware cylinder surrounds the whole, and, besides giving a neat appearance, protects the connections from injury. In the sketch the inlet and outlet pipes are shown on the same side, but, of course, they are actually at opposite sides, as illustrated in the general view of the apparatus, Fig. 1.

As the water is in direct contact with the supply, the pipes and other external metal parts of the apparatus are earthed to prevent any shock from being received from the apparatus. The water being in direct contact with the pipes also, it is necessary to reduce the leakage current to earth to a minimum. This is done by making the water columns between the diaphragms and the inlet and outlet pipes as long as possible, by providing inner pipes of porcelain as shown at *E* in the sketch. Again, to prevent anyone from receiving a shock from the outcoming stream of hot water, a small screw is placed at the end of the pipe. This effectually earths the water as it leaves the apparatus. All the metal parts of the apparatus are in direct contact with the inlet pipe, but in cases where this is connected to the supply with a rubber pipe, a special earth-wire is connected to the terminal shown on the inlet pipe.

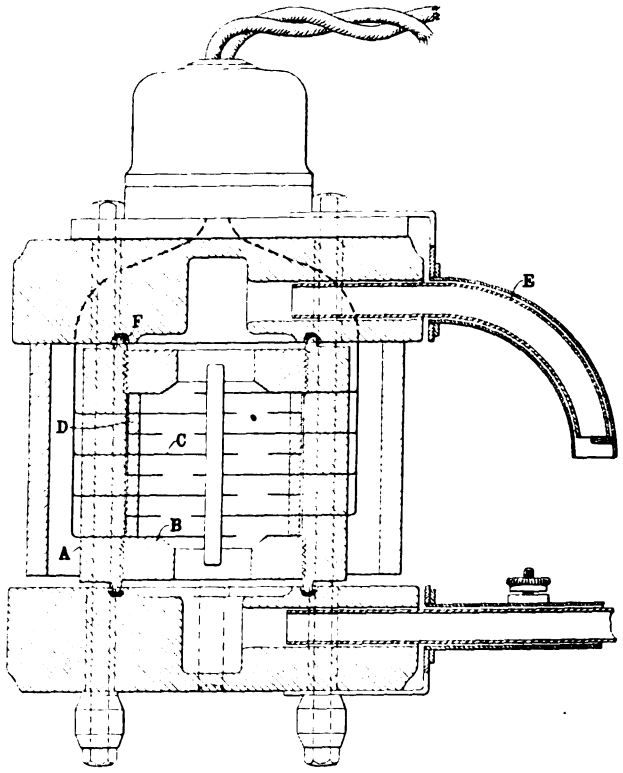

FIG. 2.—ROUGH SKETCH TO ILLUSTRATE THE WORKING PRINCIPLE.

The apparatus is constructed in a number of different sizes, having 5, 7, 9, 13, &c., diaphragms according to the quantity of water to be heated and the conductivity of the water in the locality where the apparatus is to be used. This is an important point, as the difference in conductivity is so great that a 100-volt geyser raising water to a bath temperature with full flow in London will give approximately the same temperature to the soft and pure water of Manchester or Liverpool when connected to a 200-volt circuit. In all cases the temperature of the outcoming water can be raised to boiling by reducing the flow. Where the water is very pure, as, for example, on board ship, where distilled water is used, it is first passed through an auxiliary apparatus, in which it is hardened slightly to raise its conductivity.

These geysers are made in sizes, varying from one which delivers one pint per minute and consumes 1,000 watts, to a gallon per minute geyser taking 4,000 watts. They are quite small pieces of apparatus, the smaller sizes measuring about 5 in. diam. by 6 in. high. For bedrooms, Messrs. Fuller & Son have designed an attachment for the washstand, comprising a three-gallon tank and a half-gallon per minute geyser consuming 2,000 watts. The switch and water-tap are combined, and the temperature of the water can be varied by regulating the tap. For bath-rooms, the same size of geyser is used in combination with a 20-gallon tank. The water circulates through the geyser and the tank, and in a short time the whole twenty gallons is raised to the temperature required. We are informed that by means of this arrangement the bath is filled quickly with hot water, and that with current at one penny per unit the cost of a 20-gallon bath will not exceed twopence.

A special pattern is supplied for the use of dentists and for general medical and surgical work. One interesting feature of the apparatus is that there is no fear of the apparatus burning out, as when no water is flowing there is no circuit.

THE EFFECT OF CONTINUOUS-CURRENTS IN TRANSFORMER WINDINGS

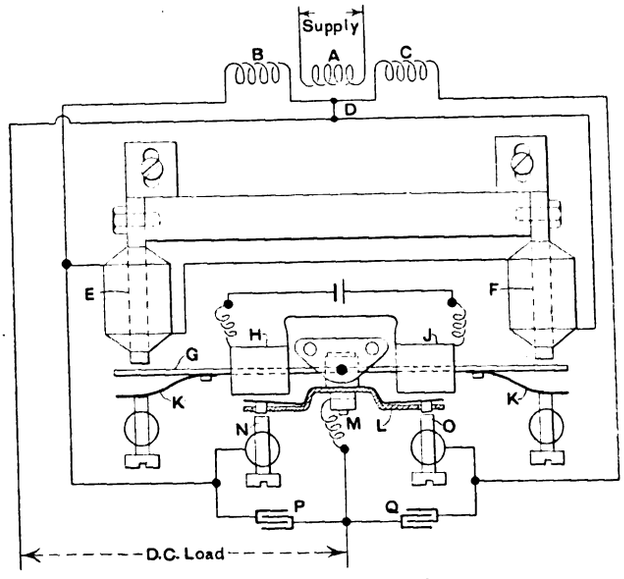
IT will be remembered that a Paper was read last session before the Birmingham Section of the Institution of Electrical Engineers by Dr. J. D. Coales on the use of transformers as choking coils for the testing of transformers. An abstract of this Paper was given in ELECTRICAL ENGINEERING of December 24th, Vol. IV., page 817.

The method described consisted in bringing the flux density of the transformer core to a high value by means of continuous current sent through the secondary winding, so that when an alternating E.M.F. is applied, the flux density undergoes variations about a mean density corresponding to low permeability instead of about zero density, as is ordinarily the case. By this means the "no load" current can be measured to a very large amount, and the insertion of a resistance in parallel enables the power factor to be varied also. The effect on the wave-form was discussed in the Paper, but the conclusion was arrived at that the wave-form was not distorted so long as the currents in the windings were above 25 per cent. of the full-load values. It was stated, however, that the core losses of the transformer rose to over four times the full-load loss under normal conditions. In the discussion following the Paper, Mr. A. R. Everest, of the British Thomson-Houston Co., stated that he had worked with high saturation of the cores in some experimental work, and had not found the iron losses to be so much greater than when working round zero flux. Prof. G. Kapp also referred to the fact that the hysteresis loss was due rather to the differences in the induction than to the maximum values of the same.

A Paper in which the above subject is dealt with was read recently by Mr. J. B. Taylor before the American Institute of Electrical Engineers at their summer meeting.

The title of the Paper is "Even Harmonics in A.-C. Circuits,' and the author begins by pointing out that electrical engineers are apt to have the misconception that even harmonics cannot exist in the wave-forms of current and E.M.F. in alternating-current circuits. After referring to the fact that the complex wave-forms of the alternating currents used for the transmission of speech in telephone work contain both even and odd harmonics, he shows how a generator can be constructed for giving an E.M.F. wave with even harmonics should that be desired. If a generator has a symmetrical armature winding and unsymmetrical north and south poles, or an unsymmetrical winding and symmetrical north and south poles, the even harmonics will not appear; but if both armature winding and poles are unsymmetrical, the E.M.F. wave-form may contain even harmonics. Again, if two standard generators, say a 25-cycle and a 50-cycle generator, be connected either in parallel or in series, the resulting wave-form will have pronounced even harmonics.

In practice, continues the author, the simplest way in which even harmonics are introduced into an alternating-current system is by the earthing of the system at more than one point, and these points may be the neutral or not. For example, in the case of a three-phase H.-T. transmission system, with the transformers connected in star on the H.-T. side and the neutrals earthed, or a single-phase railway with an earth at the sub-station and at points along the line, a neighbouring D.-C. traction system will cause a direct current of an amount depending on bonding and other features of the systems, to be shunted into the A.-C. system. This current will flow through the transformer windings, producing a magnetic flux in the iron apart from that due to the excitation from the A.-C. system. This shunted or leakage current may, the author says, be as much as, or greater than, the normal exciting current of the transformer, and thus it may happen that the iron in the transformer may be nearly saturated before any connection is made with the A.-C. circuit. It has been suggested that this condition is equivalent to a short-circuit on the transformer, as, since the iron is already practically saturated, the normal flux must be added in order to give the normal back E.M.F. This condition can, says the author, exist only for a very short interval of time on closing the circuit, however, as the iron, "instead of working from the saturated condition as a mean point, works about a point not far from zero, and in that portion of a cycle when the flux is in the opposite direction to the initial saturated condition due to direct current, enough extra current from the A.-C. circuit is supplied practically to neutralise the direct-current ampere-turns." The general effect is an increase of the exciting current, accompanied by the introduction of a second harmonic into the current wave-form. There will be some additional losses in transformers carrying current in this way, due to increased C^2R losses, and a small increase in iron losses due to the magnetic cycle being carried round a point slightly above zero.



Another way in which direct-current may be introduced into A.-C. circuits, continues the author, is by the use of a synchronous converter connected to a D.-C. three-wire system, the neutral of the latter being connected to the star point of the transformers. The out-of-balance current passes through the transformer windings, and, in the same way as explained above, causes increased exciting current and even harmonics in the wave-form. With the transformers delta-connected this would not happen. The author concludes that leakage of direct current into transformer windings will not cause any serious additional losses or overheating, unless the leakage current is very large, as the iron losses are not increased to the degree that might be expected.

In the discussion of this paper, reported in the *Electrical World*, Prof. F. Bedell, Cornell, said that direct current in the transformer increases the iron and the copper losses less than is usually supposed. Twenty per cent. direct current increases the effective value of the alternating current only 2 per cent. Mr. C. F. Scott, Pittsburgh, mentioned the case of a transformer which had a small output for its voltage relations, and considerable resistance in the primary circuit. When direct current got into the secondary circuit the magnetising current reversed and did damage. Dr. Steinmetz said that with the same height of cycle the hysteresis losses are the same, regardless of the symmetry of the wave. Eddy currents are probably increased by the greater abruptness of the change. Even harmonics are probably as frequent as odd harmonics. The constant term, which is the first term of the even harmonic, cannot exist in a machine without a rectifying device.

It is interesting to compare these statements with those made in Dr. Coales' Paper, and it would be more satisfactory if some exact figures as to the actual increase in iron losses for given values of the superposed continuous current could be obtained. It is doubtful what Mr. Taylor means by the "extra current from the A.-C. circuit . . . to neutralise the D.-C. ampere turns," but his statement that the iron losses are only very slightly increased is apparently founded on experience.

NEW RECTIFIER FOR BATTERY CHARGING

A NEW rectifier for converting alternating current to direct current for battery charging and other purposes has been introduced by the Premier Ampero Electric Co., of Premier House, Dover Street, London, W. The principle of the device is that the terminals of the circuit in which D.-C. current is required are connected to the secondary of a transformer during every alternate half-period of the cycle, so that current impulses in one direction only are passed through that circuit. To fill up the gaps between these half-waves, the circuit is connected

COMBINED DIAGRAM OF CONNECTIONS AND SKETCH OF MECHANISM OF THE "AMPERO" RECTIFIER.

in a similar manner to another secondary winding on the transformer, but with its ends reversed, so that the current impulses received are always in the same direction. A rectified current consisting of a continuous series of half-waves in the same direction is thus obtained.

The accompanying diagrammatic sketch shows how this is effected practically. *A* is the primary winding of the transformer, which is connected to the supply mains through a switch. *B* and *C* are the two secondary windings connected together at *D*. *E* and *F* are two electromagnets wound oppo-

Digitized by Google

sitely and connected in series across one (or both) of the secondary windings. The pivoted steel bar *G*, which is given a permanent polarity by means of the two coils *H* and *J* supplied from an accumulator, is set in vibration by the mutual action of the two alternating-current magnets *E* and *F*. This vibrating system is adjusted to suit the frequency of supply by varying the distance of the magnets from the bar and the tension of the springs *K*.

Rigidly attached to the bar is a stiff cross-piece *L*, which carries platinum contact pieces on springs at its extremities. These contact pieces are electrically connected to the nut *M*, which forms one terminal of the direct-current circuit. Opposite to the contact pieces are two platinum-tipped studs *N* and *O*, connected respectively to the free ends of the transformer secondaries *B* and *C*. The working of the device is now evident. When the bar *G* is moving towards *F*, contact is established at *N*, and the current impulse corresponding to the half-wave is sent into the direct-current circuit. At the instant when the current passes through zero, the bar *G* has moved to such a position that contact is broken at *N* and made at *O*, so that the current impulse corresponding to the next half-wave is sent, reversed, into the direct-current circuit. Although the current in the magnet-coils *E* and *F* may differ in phase slightly from the main secondary current, thus causing the contacts to be made and broken just before and after the current has passed through the zero point, this has little effect on the working of the apparatus, and any tendency to sparking is counteracted by the condensers *P* and *Q*, which, it will be noticed, discharge a useful current into the circuit. It may be mentioned that the condensers used are quite small, and are of the Mansfield pattern.

The magnets, vibrating bar, and terminals are neatly arranged on a slate base on top of a metal case enclosing the transformer and condensers, and the whole apparatus, of a size for supplying 12 amperes at 20 volts, measures only 10 in. square by 6 in. deep, and weighs only 35 lb. Its size and weight is thus some 50 per cent. less than a motor-generator set of the same capacity. If desired, an auto-transformer can be substituted for the two-winding transformer, the point *D* being made the middle point of the winding, and tapings being taken off at equidistant points in the winding at either side of *D* for connection to *N* and *O*. The A.-C. magnets consume only 4 watts, and the D.-C. coils on the bar *G* only 1 watt, and as the transformer has a very high efficiency, the total efficiency of the whole device is said to be over 90 per cent. This compares very well with other devices, and especially with a motor-generator set of the same output, the combined efficiency of which is generally as low as 40 or 50 per cent.

Among the advantageous features claimed for this apparatus is that it acts as an automatic minimum cut-out, as, should the supply current fail, the rectifier will stop and all the contacts in the secondary circuit will be broken, so that it will be impossible for the accumulators to discharge through the apparatus. Further, the device can work on any load from nothing up to full load, an advantage that the mercury-vapour rectifier does not possess. It can be fixed on the wall or horizontally on a table. Two sizes are listed, one for 20 volts and 6 amperes, the other for 20 volts and 12 amperes, but it is stated that larger sizes are supplied to order. We inspected a 6-ampere rectifier on Monday, and can vouch for the absence of sparking. It was shown charging a battery of accumulators, and alternatively running a small D.-C. motor.

WIRELESS TELEGRAPH NOTES

MR. H. J. TENNANT, Parliamentary Secretary to the Board of Trade, replying to a question in the House of Commons by Mr. W. Crooks, states that the Board of Trade has no records showing that wireless telegraphy has prevented strandings, collisions, and delays to shipping in fog. Instances of the use of wireless telegraphy in this connection are not reported to the Board of Trade.

In answer to Mr. Crooks in the House of Commons last week, the Postmaster-General stated that the capital cost of the Post Office wireless telegraph station at Bolt Head has been about £2,000, and its annual cost, including allowances for interest and depreciation, is estimated at about £750. The work of the station hitherto has been chiefly experimental and in connection with the arrangements for giving effect to the International Radiotelegraphic Convention. A considerable number of ships report their position to Bolt Head in passing, but happily no messages have had to be received from ships in distress. This installation was described and illustrated in ELECTRICAL ENGINEERING, Vol. IV., December 17th, 1908, p. 777.

The Special Correspondent of *The Times*, dealing with the recent cavalry manœuvres, states that "the results achieved by wireless telegraphy were anything but encouraging. Much had been expected of this novel development; and having regard to its successful use a year ago when its employment stood out as a feature in the reconnaissance scheme carried out by the Household Cavalry, it is permissible to hope that its failure during the last two days is one of only a temporary nature for which some satisfactory reason will be forthcoming. In a subject bristling with such abstruse technicalities only an expert can detect flaws, but to the layman it certainly appeared that the pack stations were decidedly wanting in mobility."

The passengers of yet another wrecked steamer have been saved by the use of wireless telegraphy. On Friday the steamship *Ohio*, of Seattle, went ashore off the Steep Point Rocks, British Columbia, but owing to the work of the wireless telegraph operator two other steamers came to the rescue, and only five lives were lost out of the 128 passengers on board. Unfortunately the wireless operator was one of these. In connection with the use of wireless telegraphy on board ship, the recent disappearance of the *Waratah* has revived the suggestion that wireless telegraph apparatus should be used compulsorily on all vessels. It is certain that the *Waratah* could have called for assistance had she been so fitted. In an interview with an *Evening Standard* representative, Mr. Marconi gave some interesting details of the arrangements made with his company by the shipping companies for fitting wireless telegraph installations. For a sum of £200, payable yearly, the Marconi Company instal the instrument and the necessary apparatus, and, moreover, provide and pay the necessary skilled operators. Beyond furnishing the space for the instrument, and, of course, quarters for the operators, the shipowner spends no more. This yearly sum of £200, even if it is only regarded as an insurance against risks, is, comparatively speaking, a small one; but in most cases part, if not the whole, of the £200 is refunded in the following manner. Out of the revenue accruing from the despatch of private messages (from and to passengers) or the "ship tax" portion thereof, the company retain the first £50 of such revenue, and all moneys received from this source, after the first £50, is equally divided between the hirer and the company. Whilst this is applicable in the case of large steamship companies, small steamers, and especially tramp steamers, carrying no passengers, and from which no revenue may be expected, present a difficulty owing to the expense. Mr. Marconi, however, thinks it possible to fit an installation on such vessels having a range of ten or twelve miles, the purchase outright of which would not be prohibitive. In this case, of course, the captain or first mate could be the operator, as the apparatus would only need to be used on very few occasions. It is difficult to see why the lives of the crew of a cargo vessel should be deemed of less importance by the steamship companies than those of the passengers and crew on their passenger vessels. In answer to a question on this subject in the House of Commons on Thursday, the President of the Board of Trade stated he did not think that any useful purpose would be served by a special inquiry into the matter at the present moment, but the matter is not being dropped in other quarters. It is said that Lloyd's intend to approach the Government on the point. Further, the advisability of lowering the premiums on vessels carrying wireless apparatus is to be considered at an international conference of underwriters at Baden-Baden next month. The *Financial Times* states that a Bill is to be presented in the French Senate to compel French shipping companies to equip all mail steamers of a certain tonnage with the apparatus, under a penalty of £200.

Until quite recently it was regarded as impracticable to employ a wireless telegraphic installation on a dirigible balloon; apart from the risk of the gas being ignited by the electric current, there were other serious dangers. The German authorities, however, says *The Times*, seem to have worked at the problem with great assiduity, and from time to time statements have been made that several of the German military airships had been equipped with "wireless" apparatus, and that satisfactory results had been obtained. One of the latest reports is that the Gross dirigible, stationed near Berlin, has been able to communicate with Frankfurt and Carlsruhe by its wireless installation.

The permit of 1903 given to the American De Forest Wireless Co. in Cuba lapsed on August 23rd last, as the Cuban Government desires to establish its own service. Since 1903 the company worked a station at Vedado, and an extension of a year has been granted in order to negotiate a further agreement with the Cuban Government.

The United Wireless Telegraph Co. is about to establish at Puerto Rico a 10-kilowatt wireless station. Several similar stations are to be installed in the neighbouring islands.

Considerable progress is being made with the installation of the wireless telegraph station at the Eiffel Tower, which it is anticipated will have a range of 3,750 miles by day and further by night. We published an illustrated account of this in ELECTRICAL ENGINEERING, Vol. IV., p. 843, December 31st, 1908.

In connection with the installation of Mr. C. E. Kelway's sound-locating system at Dover, the Postmaster-General has been compelled, after consultation with the Admiralty, to refuse the grant of a licence to him for its installation at Dover or on the south or south-east coast of England, owing to the system involving the use of wireless signals. The reason for the refusal was the risk of interference with the naval and commercial wireless telegraphy which is so largely carried on in those regions. A licence was, however, offered to Mr. Kelway for the trial of his system in some locality where this objection did not apply.

BREAKDOWNS OF ELECTRICAL MACHINERY

THE report of Mr. Michael Longridge, the chief engineer to the British Engine, Boiler, and Electrical Insurance Co., Ltd. (12 King Street, Manchester), for the year 1908, which has just been issued, contains, as on previous occasions, interesting particulars of typical breakdowns of electrical machinery and hints how to avoid such occurrences. Before dealing with that portion of the report which refers to electrical plant, however, we may quote from the first section—steam-, gas-, and oil-engines.

Contrary to what might have been expected, the rate of increase in the number of engines insured has been practically the same for steam as for internal combustion engines. There is no doubt, says Mr. Longridge, that while small steam engines have had to give place to gas engines, gas engines in their turn have had to make room for electromotors. The ratio of breakdowns in the case of steam engines has been 1 in 9·4 insured, and in gas engines 1 in 9·1 insured. Mention is made of the continually increasing percentage of the accidents due to breakages of valves and valve gears of steam engines, increasing from 23·3 per cent. of the total breakdowns of this class of engine in 1906, to 28 per cent. in 1907, and 34·8 per cent. in 1908. It is suggested that more strength, and certainly more care in fitting and screwing nuts, screws, pins, and cotters, would reduce this figure. The reduction in the breakdowns of spur gearing from 12 per cent. in 1906 to 10·2 per cent. in 1907, and to 8·1 per cent. in 1908, simply records the rapid disappearance of this kind of gearing from the engine-rooms of textile mills and factories.

The branch of the company's business devoted to the inspection and insurance of electrical machinery shows an increase of 11·4 per cent. in the number of insurances current, the number of breakdowns having risen almost in proportion—by 10·7 per cent. The proportions of breakdowns in A.C. generators is the highest, namely, one in 5·7 insured; in A.C. motors one in 11·3; D.C. dynamos, one in 13·7; D.C. motors, one in 9·2; and starters and controllers, one in 24. Analysing these figures further, it is found that slightly more than half the breakdowns in dynamos and motors have been traced to the failure of the rotating parts of the machines.

In the case of D.C. motors, 38 per cent. of the failures have been due to the armatures and 29 per cent. to the commutators, while with A.C. motors the greater part of the accidents (53 per cent.) have been due to the stator coils. It is noteworthy that 52 per cent. of the trouble with starting switches and controllers has been caused by the resistance coils. A further table gives the proportion of breakdowns due to dirt and neglect as 23 per cent. in the case of generators, 30 per cent. for motors, and 17 per cent. for starters. A careful perusal of the report by the firms insured should result in a reduction of these figures. We select a few of the typical cases described:

The first two of these illustrate the danger of leaving small pieces of iron near dynamos and motors. In the case of a 26 kw. two-pole under-hung open-type dynamo, a small tapered pin belonging to the engine, which had evidently been laid down near the dynamo during overhaul, had been drawn in between the armature and the pole face, with the result that four of the armature bars (stranded conductors ⅜ in. by ½ in.), had been cut in two, and the end connections to six others had been bent. A nail which had travelled to a similar position in a 2 h.p. two-pole semi-enclosed motor geared to a nailing machine, had also done sufficient damage to necessitate the entire rewinding of the armature. Obviously two-pole machines, with their large stray field, are the most susceptible to accidents of this nature.

A remarkable accident occurred in the case of a 5 h.p. motor coupled to a machine by a belt. The armature bearings had ring lubrication, and its oil wells were fitted with drain cocks. The belt caught one of these cocks, let out the oil, and the bearing ultimately seized. "The accidental opening of these drain cocks," Mr. Longridge says, "is by no means so rare an occurrence as might be supposed, and it does not seem unreasonable to suggest that they should be made in such a way as not to be liable to be opened by the chance touch of a jacket, a cleaning rag, or a belt, if there be one near."

Neglect of cleaning and lubricating has been responsible for much trouble, as has already been indicated. In one case the oil well of a bearing was found to have been so full of dirt that the lubricating ring could not revolve, the white metal in the bearing had melted, and the armature had rubbed against the pole faces, stripping one of the wire binders, and cutting up the insulation of the conductors. Short circuits are apparently frequently caused by accumulations of carbon dust and oil behind the commutator lugs, and in one case this occurred in spite of an air compressor being used to provide a strong blast for the purpose of keeping this part of the commutator clean, as the presence of oil rendered it ineffective. The report says that the passage of oil to the back ends of commutators is very difficult to prevent, and is most troublesome in its effects, as it cannot be removed. It does not take place when commutators are pressed on to their shafts, but no care in fitting seems able entirely to prevent it. When quills are held by feathers or screws the only satisfactory plan appears to be to caulk a copper ring between the shaft and the front end of the casting.

A 10-h.p. three-phase motor, placed in a pit below the floor of a boiler shop, and driving plate-bending rolls by gearing, had been a source of anxiety to the company for some time, owing to its inaccessibility, and the owners had been urged, but without effect, to have it taken up to have the rotor taken out and the stator thoroughly cleaned. Finally it broke down by failure of the insulation between the stator windings and the frame. The slots were found to be full of dust and oil, and the insulation saturated.

Complaint is also made of the accumulations of dust which are generally found under string binders, and especially under the string bands which are sometimes put round the conical clamping rings at the ends of commutators, with the object of increasing the length of the insulating band between copper and iron. In another motor it was found that the insulating troughs in which the armature coils were carried only reached half-way up the sides of the slots, so that several turns of each of the top coils had nothing but their own cotton covering to insulate them from the core.

An interesting case is mentioned, as a warning, in which the owners of a motor had been turning the commutator in their own lathe, and had set it to work without taking care to clean the copper dust out of the mica between the bars, or seeing that there was no bridging from bar to bar before replacing the armature in its bearings. This case, we regret to learn, is typical. After commutators have been turned they should be carefully examined. The most risky places are the corners where the lugs spring from the bars.

A disaster happened to a 13-kw. six-pole d.c. dynamo, driven by eight ropes 1¾ in. diameter, with the driving spans uppermost. The diameters of the driving and driven drums were 10 ft. and 19 in., and the distance between their centres 17 ft. One of the ropes broke while the machine was running, and one of the loose ends fouling the outer bearing, tore the machine bodily from the foundation rails, and dragged it into the bottom of the rope race, 6 ft. below. The bedplate, bearings, and pulley were broken, the armature windings damaged, and the brush gear smashed. Mr. Longridge points out that the accident was not surprising. If the dynamo ran 10 hours per day it must have made about 117 million revolutions every year, and each part of the rope must have been bent round the semicircumference rather more than twelve million times per year. Moreover, at each bend the part of the rope furthest from the centre of the pulley must have been lengthened by about 1½ in., and the part nearest the centre shortened by a like amount, a difference between the two surfaces of about 3 in. in 30 in., the semicircumference of the pulley. If the diameter of the dynamo pulley could not be increased beyond 19 in., the power should have been transmitted by a belt.

Brushes and brush-holders have given considerable trouble. In a completely enclosed four-pole shunt-wound 27 h.p. d.c. motor, three years old, each of the four brush-holders contained one carbon brush, with V-shaped head, fixed in a corresponding slot through the end of the brush-holder, and the foot of the brush resting on the surface of the commutator. The brush was prevented from coming out of its slot by a small set-screw passing through the top of the brush-holder and pressing on the flat top of the brush. On being summoned to ascertain what had gone wrong with the motor, the district inspector found one of the brushes in the bottom of the motor casing, and the brush-holder resting on the commutator and considerably worn down. The brush must have fallen out at an earlier date, and allowed the brush-holder to drop on to the commutator, there being no stop on the spindle to prevent this. Similar mishaps appear to be of frequent occurrence when no provision is made for supporting the brush-holder independent of the brush. It is said that the company has probably had least trouble with brush-holders consisting of a plain box holding a rectangular block of carbon, with a flexible conductor attached, and a spring to keep the carbon up to the commutator surface.

Loose-core discs are still an occasional source of trouble. In a four-pole semi-enclosed shunt-wound d.c. motor, four years old, giving 10 h.p., the nut which held the core plates was found

Digitized by Google

screwed back off the thread on the shaft, so that all the plates were loose. Forty-six out of a total of 58 conductors were broken, and the rest quite unreliable. The nut had been a slack fit on the shaft, and had not been fastened by lock nut or taper pin. It is suggested that core plates can be held endways more safely by a ring sunk in a circumferential groove on the spindle than by a nut, but the bottoms of the grooves for such rings should be rounded and not square-cornered as they so often are.

In commenting on two cases in which the ends of armature windings have been cut, Mr. Longridge says that "common sense should suggest that the edges of end plates and winding drums over which thinly-covered conductors pass should be well rounded, and that the conductors should be still further protected by strong presspahn or other insulating material. It is not possible to prevent entirely relative movement between the conductors and the core or winding drum, and it is certain that any movement, however slight, will enable a sharp metal edge to cut through the thin covering of an armature conductor. This relative motion is also responsible for another large class of accidents, the fracture of armature conductors at their junctions with the commutator arms. The usual methods of preventing the rotation of armature spiders and commutator quills, and still more of armature core plates threaded upon the shafts, by feathers, projecting screw heads, and set-screws are not effective either because the bearing surfaces are insufficient, or because the fitting is not good enough. The best plan when the diameter permits undoubtedly is to build both armature and commutator upon the same casting."

In concluding this portion of the report, the following comments are made:

The general impressions left upon the minds of those in charge of the electrical department are that a very large majority of the breakdowns are due to the deteriorating effect of oil, dust, and damp on the materials used for insulating. Of these oil is the most injurious and most difficult to deal with. Better arrangements are needed to prevent oil throwing. If oil once gets out of a bearing it creeps along the shaft to the back of the commutator and on to the end windings, also on to the commutator insulation and brush gear, and mixing with copper, carbon, or other dust, forms short circuits, giving rise to carbonisation and "burning out." The next most fruitful cause of damage is probably imperfect fitting, keying, and locking of spiders and core plates, commutator bushes, and even pole pieces, leading to abrasion of insulation and "earthing." Careless winding and fitting of magnet coils is also sufficiently common to be noted. Lastly, many of the users of electrical machinery do not give it the attention it requires. They fix motors in places which are difficult of access, dusty, or dirty, and leave them to work as best they may. If motor bearings were made like bicycle bearings, with balls running in vaseline, and if the armatures were regularly blown out, and the brushes attended to, the number of breakdowns would be far fewer than they are.

Some interesting notes are given on the subject of speed control of motors.

It appears that many people think that if a controller containing resistances in series with the armature of a motor will give certain variations of speed at full load, the same controller will give the same variations at light load. An example is worked out at length to show that this is not the case. It is pointed out that control by resistance in the shunt circuit has, on the other hand, a high efficiency, and can be used with modern motors with inter-poles for a speed variation of 1 to 6; to show that this efficiency, however, is only obtainable at a higher first cost, an extreme case is taken: A motor with speed control by resistance in series with the shunt, capable of giving 85 h.p. at 420 revolutions per minute with all the controlling resistance in, and the same torque at 80 revolutions per minute with all the resistance out, would have to be large enough to give 450 h.p. at 420 revolutions per minute with no resistance in series with the shunt. In other words, to get the efficiency due to shunt-speed control a 450 h.p. motor must be put down instead of an 85 h.p.

We have dealt with Mr. Longridge's report at considerable length, for it contains a mass of practical information which cannot fail to be of service to motor users, who represent an extremely large proportion of our readers. We have no doubt that the British Engine, Boiler, and Electrical Insurance Co. would be pleased to send copies of the report to any who should desire to study it in further detail.

Exigencies of space prevent us from dealing at length with the section on boiler inspection, and we will content ourselves with quoting one amusing item.

Early in the year the company was asked by an intending purchaser to examine a second-hand Lancashire boiler 30 ft. long by 8 ft. in diameter offered to him by a broker as fit to work at a pressure of 120 lbs. per square inch. Arrangements having been made with the broker, an inspector was sent to make the examination. He found the boiler on its seating empty, but neither cleaned nor swept, and the mountings lying in a field near by exposed to the weather. They were therefore dirty and rusty, but were otherwise in good order and well made. The boiler was structurally fit for the pressure stated, and so far as could be seen for deposit but little the worse for wear, except for some grooving in the flanges by which the first rings of the internal flues were attached to the front end plate. This grooving in general varied from $\frac{1}{16}$ in. to $\frac{1}{8}$ in. deep, and would not have been serious had there not been a fine crack at the bottom of it. In one place, about 3 in. long, the crack had extended through the plate and leaked. As regards the grooving, if not in the matter of cleaning, the boiler appeared to have been prepared for the inspector, for the grooves had been filled with red lead, which had been smoothed down to the surface of the plate, rubbed over with tallow, and dusted with powdered deposit to look like the adjacent plate surface. But for the signs of leakage on the fire side, the crack might have escaped the eye even of an experienced inspector, for the work on the inside surface was quite artistic. The outside, however, had been overlooked, and gave away the artist.

THE "MAURETANIA" AT FISHGUARD HARBOUR

THE new route between London and New York was inaugurated by the Cunard liner *Mauretania* on Monday last when she landed her passengers at Fishguard, Pembrokeshire, for the first time, and on the same occasion broke all previous records by accomplishing the homeward voyage to Queenstown in 4 days, 14 hrs. 27 min., over two hours less than her previous best voyage from New York.

Fishguard Harbour was opened by the Great Western Railway Co. in August, 1906, just three years ago, and has been used since that date in connection with the new service to Ireland. Within the last year the traffic has increased considerably; the steamers of the Booth Line having used the harbour for some months. The harbour works comprise two large quays, the Ocean and Station quays respectively. The latter has been completed for some time, and was the quay at which the *Mauretania* landed her passengers with the aid of tenders. When the Ocean quay is complete, it is hoped that it will be possible to bring up such large vessels as the *Mauretania* alongside, and thus dispense with the services of tenders.

A very complete and illustrated description of the electrical equipment of the harbour was given in ELECTRICAL ENGINEERING of February 28th and March 7th, 1907 (Vol. I., Nos. 9 and 10). There are nine electric cranes on the Station quay, for loading and unloading vessels alongside, one on the coaling wharf, and already two on the Ocean quay, which is not yet complete. The former cranes are arranged to travel along the quay, and are each capable of lifting a maximum load of 30 cwts. at a fixed radius of 35 ft. Separate motors are employed for lifting and slewing, the former being of 38 b.h.p. capacity, and the latter 4½ b.h.p. The full lifting speed is 250 ft. per minute, and the speed of slewing 400 ft. per minute at the jib-head. The coaling crane is designed to lift a load of 21 tons at a fixed radius, and is fitted with a cradle capable of carrying and tipping a railway truck with its load of coal. The lifting motor is rated at 56 b.h.p., and gives a speed of lift with the full load of 26 ft. per minute. The slewing motor is of a capacity of 8 b.h.p., and is capable of slewing at a maximum speed of 200 ft. per minute at the jib-head. Three electrically-driven capstans are provided in the station between the tracks for general use in shifting trucks and carriages. These are each designed to give a pull of one ton at 200 ft. per minute. The capstan-head is geared by a single reduction worm-gearing to a 22 b.h.p. motor running at 500 r.p.m. There are also four electric traversers to enable passengers to cross from platform to platform independently of the subway. Each is fitted with two motors, one for travelling the whole machine forward from its position under the platform to its position across the track, and *vice versâ*, and the other for lifting the upper portion to the platform level.

The power-house is situated at the northern end of the harbour, right under the cliff, but in such an exposed position that special precautions had to be taken to protect the machinery from falling pieces of rock breaking through the roof. It is a steam plant generating continuous current at 480 volts. A feature of the steam-raising plant is that each boiler has its own short iron chimney, as the conditions of the site did not admit of a single brick chimney. A full description of the generating plant, battery, and distributing system was given in the previous article. The marine engineering shops, which were then mentioned as being under construction, are now complete, and in full working order. A very complete lighting system is provided, and the station buildings are heated electrically also.

ELECTRICAL INSTALLATIONS IN COAL MINES

A COMMITTEE is to be appointed to revise the Home Office Regulations relating to electrical installations in coal mines.

In the House of Commons on Thursday, Mr. John Wilson asked the Home Secretary whether he had noted the prominence given by Professor Redmayne, Chief Inspector of Mines, and Mr. R. D. Bain, Inspector of Mines in Durham, in their report on the West Stanley explosion, to the dangers arising from the use of electricity in mines, and to the statement in the report that on the assumption that the explosion did originate in the Busty seam they were of the opinion that electricity was a more likely first cause than any of the alternatives already discussed. Mr. Gladstone was further asked whether he was aware that all the evidence given at the inquest by mining experts and other witnesses went to show that the explosion originated in the Busty seam, and whether he would arrange a commission of inquiry into the danger involved in the use of electricity in mining operations.

The Home Secretary, in reply, said he had these reports under consideration, as well as other reports which had reached him from time to time in regard to the use of electricity in mines and the working of the Special Rules for the Use of Electricity in Mining. Since the inquiry five years ago, which resulted in the issue of these rules, much further experience on the subject had been obtained. New points had arisen, and the special rules, the working of which had been carefully watched by his department, had shown themselves in need of amendment on a number of points. He proposed, therefore, to appoint a small expert committee to revise the rules in the light of the experience which had now been gained of their working.

We have already dealt at some length with the evidence with regard to the possible cause of the explosion at the West Stanley pit, alluded to by Mr. Wilson. In our issue of April 8th (p. 324) we gave a summary of the evidence heard at the Coroner's inquest and the conclusions to be drawn from it, which were confirmed by the report by Prof. Redmayne and Mr. Bain, were summarised in our issue of August 19th (p. 742). It is practically certain that the cause of the disaster was the explosion of coal dust, and decided suspicion is cast upon the electrical equipment as the means by which it was ignited. It is quite within the bounds of possibility that, as suggested by Mr. R. Nelson, the Electrical Inspector of Mines, some 7/20 rubber cables supported from the roof and side timbers in the Busty seam, where the explosion is thought to have originated, might have been severed by a heavy fall of stone, and that the arc ignited the explosive mixture. Other parts of the electrical equipment were also called into question during the inquiry, but less suspicion falls on them.

There have recently been several cases of death from electric shock in coal mines, and we welcome a revision of the regulations referred to, and trust also that they will in the future be stringently enforced. There are, we believe, many mines—notably in Scotland—where there is a neglect of proper precautions to ensure the safe working and adequate inspection and testing of the electrical plant below the surface.

The most recent accident occurred in the Cribbwr Fawr Colliery in Wales, on August 12th, where two workmen were killed by electric shock; and this would probably have been avoided if the most reliable method had been followed with regard to the earthing of the cable sheathing. In this case the shock was received from a vulcanised bitumen three-core cable, which was armoured but not lead-covered. The continuity of the armouring was interrupted at junction boxes (which had compound glands), and instead of the cables being bonded across the junction boxes so as to give a continuous circuit to the power station earth at bank, the armouring was earthed at each box. Although the method of earthing employed must have given practically as much trouble to carry out as that with continuous bonding, and certainly entails more work in inspection and testing, yet it is by no means so efficient, and is more liable to failure—as was, in fact, shown by the fatal accident which happened. The earthing of each point was effected by strips of galvanised iron about 18 in. long and about 1¼ in. wide, buried in the ground, and connected to the armouring by wire wound round it. Most of these, it is true, were in damp places, but there was always liability for some to become dry, in which case the connection would be useless as an earth. The cable was fixed to the roof, and it was damaged by a run-away of tubs which piled up and came in mechanical contact with the cable. The cable, it is said, was tested and found good after this run-away, but it broke down the next day, by which time no doubt the dampness had penetrated through a break in the insulation, and the two men were killed by shock on coming in contact with it. The pressure was 440 volts (three-phase, 50 cycles). When the Special Mining Rules are revised, we trust that one will be included insisting on the use of armoured cables, continuously bonded and earthed.

THE GERMAN ELECTRICAL INDUSTRY IN 1908-9

IN his report upon the electrical industry in the Frankfort Consular district for the year to April, 1909, Sir Francis Oppenheimer, as usual, goes a good deal beyond his Consular boundaries, and surveys the present position of the industry in Germany generally.

Whilst it is admitted that the economic depression has not seriously affected the electrical industry, nevertheless, business in 1908 cannot be described as satisfactory in comparison with the results of the immediate past. Whereas 1907 showed an upward movement, a change took place in the second half of 1908. The threatened danger of the introduction of a tax on electricity also seriously affected the industry. Such a tax on electric energy would have really constituted a double burden upon the entire industry of the country, and its effect would have been far-reaching. It was strongly opposed by Chambers of Commerce, municipalities, and societies of all kinds. Equally strong protests were raised against the law suggested by Prussia, which aimed at a closer supervision of the whole industry. Additional difficulties arose through the contemplated Prussian company tax, and numerous electrical companies have already decided to remove their offices from Prussia (*e.g.*, die Deutsche Ueberseeische Electricitats Gesellschaft) to one of the Hanse towns should this tax become law.

During the year no technical innovations of an epoch-making nature were introduced. Patents which have for years been in practical use were further successfully exploited, though, according to the return of the Imperial Patent Office in 1908, as in previous years, the electro-technical industry holds the record amongst the various groups of inventions applied for, viz., 2.721. This same group also, as in previous years, holds the record for the highest number of patents granted. From 1877 to 1908 there have been applied for in this group 30,483 patents, and granted 11,749—which is by a long way the record.

Reciprocating engines are being more and more displaced by steam turbines. Entirely satisfactory results were attained with high-voltage transmission systems up to 15.000 volts, orders for high-tension plant having increased considerably during the year. In telephony the central battery system was further extended. A constant development also continues in the electrical equipment of mines and smelting works. Large numbers of electric locomotives were adopted for use in mine and industrial railways generally. The experiments with electric traction in Hamburg yielded satisfactory results, and important plans by the Baden and Prussian railway administrations are awaiting development.

Large power schemes are now attracting great attention, and the prospects for the year 1909 are, on the whole, described as good.

Business in dynamo machines and electric motors was not during the greater part of the year very satisfactory; almost everywhere it was worse than at the same time in the previous year, in consequence of a receding demand. For instance, the output of the A.E.G. was 1.350,327 h.p. in 1908-9, against 1.161.060 h.p. in 1907-8, and the Lahmeyer Co., 358,000 h.p., against 382.000 h.p. in the previous year.

With regard to electric lighting and power transmission, the collapse in the price of copper had a favourable effect on manufacturing costs, although it did not lead to an appreciable increase in profit, owing to severe competition. The factories for insulating material were, on the whole, well employed, but a change took place in the course of the year, which lessened employment somewhat. The depression also made itself felt in the electrical measuring instrument industry. The turnover effected was only achieved with great difficulty and sacrifices, and prices showed a downward tendency. Even if the totals of import and export remained unchanged, yet in the case of certain countries the export, owing to the unsatisfactory con-

Digitized by Google

ditions as to customs dues, has practically become impossible. The reports from the electric arc lamp works are not uniform, but the business results were, on the whole, satisfactory. A decrease in the home business was balanced by the export, so that the total output was even increased. The keen competition between gas and electricity for lighting purposes spurred the arc lamp industry to further experiments. In this branch, as in others, the import duties in various countries weigh so heavily upon the manufacturing costs that an export is absolutely impossible. The progress of the carbon manufacturing industry was satisfactory.

The development of electric power stations and electric railways would have been satisfactory had not the contemplated Imperial electricity tax interfered towards the end of the year. A number of large schemes were postponed, which, under other circumstances, would undoubtedly have been carried out. The number of light railways, which, according to the statistics for 1906, amounted to 176 electrically driven lines with a total length of 5,534 km., and an installation value of over 850,000,000 marks, has increased very considerably during the year under report. The electrification of wide-gauge railways has made good progress, and much is expected from this development for the future. In connection with the development of large railway undertakings, chiefly high pressure, continuous and single-phase currents are to-day used. The use of three-phase current will decrease more and more in consequence of the difficulty of erecting the conductors.

Though the second and third quarters of 1908 witnessed a decreased export of electrical products, there was a lively demand for capital in the last months of the year, which the more important works needed for preparing new undertakings.

New issues, investments, and increases in capital of the electrical companies for the year 1908-9 amounted to 78,330,000 marks, compared with 42,365,000 marks in 1907-8. New power stations are not included in these sums; if they be included, the new investments of the year 1908 would probably by far exceed 100,000,000 marks, as against an estimate for 1907 of from 50,000,000 to 60,000,000 marks, and for 1906 from 70,000,000 to 80,000,000 marks. In the year 1907, it will be remembered, the conditions of the money market were unfavourable to any financial operations upon a large scale. The average dividend of 45 electric companies, controlling together a share capital of 573,245,000 marks, has been calculated at 8·1 per cent. for 1906-7, and 8·3 for 1907-8.

That the industry is preparing for further large expenditure is shown by the formation of the two electrical banks. The bank "Elektro-Treuhand Aktiengesellschaft" was founded by the Allgemeine Elektricitäts Gesellschaft, Siemens & Halske, and Siemens-Schuckert Werke, on November 26th, 1908; the share capital amounts to 30,000,000 marks. The Elektro-Bank of the Felten-Guilleaume-Lahmeyer concern was formed with a share capital of 25,000,000 marks; debentures are to be issued to triple the amount of the share capital—that is, up to 75,000,000 marks. The share capital, invested in trust investments, is to serve as guarantee capital for the debenture debt.

National Telephone Co.'s Service.—In answer to a question in the House of Commons last week by Mr. John Ward, M.P. for Stoke-upon-Trent, the Postmaster-General stated that the numbers of the construction staff of the National Telephone Co. are constantly fluctuating. He was informed by the National Telephone Co. that since the beginning of this year they had discharged eight men and one boy from their construction staff in the Potteries district owing to slackness of work. There appeared to be at the present time a considerably reduced demand for the extension of the telephone system, due partly to the fact that the telephone system had made very rapid extensions of late years, and that there was therefore not the same opening for new construction; and, further, that the state of trade had of late seriously affected the demand for new telephone installations. As regards the Post Office system, there was also, for the time being, less work in connection with renewals, as the old plant had of late been largely superseded by new and more permanent plant. As regards the trunk lines also, during the last few years lines had been added in anticipation of traffic, and there was at the present moment less opportunity of extending them. This being so, it was not possible, unfortunately, to undertake to engage men discharged by the National Telephone Co. on Post Office work, but this was done as far as possible. He had, however, come to an arrangement with the National Telephone Co. in regard to certain construction work; and was also in communication with them in regard to a proposed arrangement to enable them to continue to open new exchanges in their areas, in order that the work of construction shall be continued without interruption between now and 1911. In this connection the National Telephone Co. authoritatively repudiates the suggestion that the service is being starved. Not only is this the case, but no complaint whatever has been received from the Government, and no difficulties, at all events as regards the proper upkeep of the plant, are anticipated in connection with the agreement with the Government for the purchase of the company's undertaking.

NEW YORK TUBE RAILWAY TERMINUS

THE twin tube tunnels of the Hudson & Manhattan Railroad Co., extending from the Hudson Terminal Buildings at Church and Cortlandt Streets, New York, to the Pennsylvania Railroad station in Jersey City, were opened to the public on Monday, July 19th. The tunnels are the second pair of tubes under the Hudson River to be put in operation. According to the *Electrical World* (New York), the tubes under the river are a mile long, and are circular in section, formed by a segmental cast-steel shell bolted together and lined with concrete up to the level of the top of the cable ducts; the top half being unlined. The diameter in the clear is 15 ft. 3 in. The terminus occupies three floors below ground. The station platforms are 370 ft. long, and permit the operation of eight-car trains. The platform level is lighted with five-lamp ceiling clusters enclosed in ground glass-bowls. The edges of the platform are also illuminated with rows of incandescent lamps. Most of the ceiling clusters are connected to 240-volt, three-wire, direct-current lighting mains, which also supply the offices on the upper floors of the buildings. At frequent intervals, however, a cluster of five incandescent lamps, forming part of the ceiling illumination, is connected to the third-rail circuit. This ensures against total darkness in the station in case the lighting circuits to which most of the ceiling fixtures are connected should fail. The lamps on the edges of the platform are also connected to the railway circuits. No automatic switches have been installed to cut in outside sources of energy in case the local supply should fail; but the switchboard in the sub-station of the building is connected through a hand-operated switch with the mains of the New York Edison Co. A large storage battery which floats on the building lighting circuits affords a supply of electricity for short periods without any interruption to the lighting circuits should the rotaries in the sub-station or the generators in the power-house on the Jersey shore momentarily fail. There are six illuminated train-announcer signs on each platform.

In the basement, below the train platform level, a large sub-station has been constructed where the high-tension, alternating current is converted into 625-volt current for the railway circuits and to 240 volts for the lighting circuits in the buildings. The sub-station contains at present two 1,500-kw. General Electric rotary converters for railway load, and four 750-kw. rotaries for lighting load. Foundations are provided for two additional 1,500-kw. units, giving the sub-station an ultimate output of 9,000 kw. Each of the railway units has a separate set of three 750-kw., air-cooled transformers, taking 25,000 25-cycle current and delivering 390-volt current at the secondaries. The rotaries deliver 625-volt, direct current to the third-rail feeders. Each of the four lighting units is supplied from three air-cooled transformers. The sub-station is lighted by Cooper Hewitt mercury-vapour lamps suspended from the ceiling. Cooling air for the transformers is supplied by motor-driven fans taking air from an intake running from the roof.

Drying out Flooded Machines.—M. S. von Jankowsky, an engineer in the Kramatorskaja Ironworks, South Russia, describes in an article in the *Elektrotechnische Zeitschrift* the method adopted at these works to dry out nine three-phase motors of outputs of from 6 to 50 h.p., which had been half under water for three days in consequence of a flood which occurred last March. Hot air is supplied under pressure to the furnaces in the works from a Cowper plant, and a flexible metal pipe was attached at one extremity to a branch pipe from the main hot-air pipe. The motors, which had been assembled together on a truck with the rotors and stators separated, were then played on with the stream of hot air. In the main pipes the temperature of the air was 800° C., but at the end of the flexible pipe it had fallen to 220° C., and the spray was held at such a distance from the windings that the air temperature was about 150° C. It is stated that the treatment was very successful, the water being blown out of the windings, and the remaining moisture evaporated in a very short time. In forty minutes a complete machine was thoroughly dried out, giving a very satisfactory insulation resistance immediately afterwards. Before being put into use, however, the machines were run for four hours on no-load. These motors have now, says the author, worked for two months without showing any ill-effects from the flooding or the drying-out treatment. The only drawback to the treatment was that much dust was blown through with the hot air, but great care was taken to protect the bearings while the drying was in progress, and the windings were thoroughly cleaned afterwards. Had the usual method of drying-out in a hot-air chamber been adopted it would have taken a week to complete the drying, including dismounting and re-erecting the motors.

CATALOGUES AND PAMPHLETS RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

LAMPHOLDERS AND ACCESSORIES.—A price list of some twenty pages devoted entirely to lampholders and fittings is to hand from the Adnil Electric Co., Ltd. (26-30 Artillery Lane, Bishopsgate Street Without, London, E.C.) The list is fully illustrated, and includes prices and particulars of many patterns of lampholders and lamp fittings for special purposes.

SPECIAL TUMBLER SWITCHES.—Messrs. A. P. Lundberg & Sons (Pioneer Electrical Works, 477 Liverpool Road, London, N.) have sent us a pamphlet describing several patterns of tumbler switches for special purposes, utilising the firm's patent "Duplex" switch movement, which gives two "on" positions and a central "off" position. The patterns listed include a two-way and "off" switch; an adaption of this for heaters and electroliers with "part on," "all on," and "off" positions; a series-parallel switch for lamp control; a reversing switch with an "off" position; and starting switches for D.-C. and A.-C. motors, those for the latter type having a knob which flies back from the starting to the "off" position if released. The various applications of these different switches are fully described with the aid of diagrams.

JANDUS ARC LAMPS AND ACCESSORIES.—The Jandus Arc Lamp and Electric Co., Ltd., is now issuing an attractive catalogue, in which special attention has been paid to the regenerative flame lamp, but full details are given of the ordinary enclosed lamps, photographic lamps, colour matching lamps, and arc lamp accessories. We are asked to mention that inquiries for this catalogue should be addressed to Hartham Works, Holloway, London, this being now the sole address of the firm, who have acquired a suite of offices adjacent to the works.

WATER-TUBE BOILERS.—A pamphlet received from Messrs. Hawksley Wild & Co., Ltd. (Brightside Boiler Works, Sheffield), gives particulars of the firm's patented "Suckling" water-tube boilers for both land and marine purposes. The chief features of this boiler are the large tubular connections at the extremities of the drums, which, being at widely different temperatures, ensure a good circulation; the method adopted in expanding the tubes into the drums; and the vertical arrangements of the tubes at right angles to the path of the hot gases. We are asked to state that inquiries should be addressed to the London office, Queen Anne's Chambers, Westminster, S.W.

IGNITION COILS, ACCUMULATORS, &c.—We have received a new catalogue from Messrs. John C. Fuller & Son (Woodland Works, Wick Lane, Bow, London, E.) of all the electrical accessories manufactured by the firm for automobile use. It includes all the latest patterns of trembler and non-trembler coils, ignition accumulators, carriage-lighting accumulators, magnetos, dry cells, and mercury-bichromate charging batteries. Other specialities of this firm, including hand-lamps, carriage-lamps, and gas- and petrol-driven sets, are also listed. Full particulars and prices for each item are given, and the catalogue is well illustrated.

ARC LAMPS AND ACCESSORIES.—A new pamphlet is being issued by the Globe Electric Co., Ltd. (11 Farringdon Avenue, London, E.C.), the sole makers of the "Santoni" flame arc lamps. This includes illustrated descriptions of flame lamps for street and shop lighting, single and double enclosed lamps, inverted open type lamps for indirect lighting, and the "Santoni" lowering gear. Full particulars, dimensions, and prices of the various sizes of lamps are given in each case, and special lists of spare parts and of various sizes of the firm's special coppered flame carbons are also included.

ELECTRO-MEDICAL APPARATUS.—The Dowsing Radiant Heat Co., Ltd. (24 Budge Row, Cannon Street, London, E.C.), have sent us a new list of electrical appliances for medical purposes. These include electric light and heat baths of various patterns, both portable and otherwise; switchboards and apparatus for supplying current for the "galvanic," "faradic," and "sinusoidal" treatments; a chair with water baths for feet and hands, and pad electrodes for applying the current to any portion of the body; electrical vibratory apparatus; and finally, high frequency apparatus.

TELEGRAPHIC APPARATUS.—A pamphlet describing a selective calling apparatus, which makes it possible, on a telegraph line with many stations, to call up any individual station by means of a bell signal, without disturbing all the other stations, is to hand from Messrs. Siemens Bros. & Co., Ltd. (Caxton House, Westminster, London, S.W.). The apparatus is particularly adapted to telegraph lines where the operators are obliged to attend to other things besides their instruments. No alterations are necessary to the existing apparatus, as the selective device is merely an accessory. The working of the telegraph is independent of the working of the device which is operated by means of the existing morse key. A call-bell can be fixed at any convenient distance from the apparatus, and the call is automatically restored by the ordinary telegraph working.

LOCAL NOTES

ABERDEEN: *Supply to Tramway Company.*—In consequence of the Aberdeen Suburban Tramways Co. having complained of the high charge made by the Corporation for electrical energy, Mr. W. H. Patchell was appointed arbitrator to settle the difference of opinion. Mr. Patchell's finding was that the price should be a standing charge of £900 per annum plus 0·5d. per unit for all energy used, this charge to hold good for five years. The company now refuse to be bound by this decision on the ground that it is *ultra vires*, for the reason that the arbitrator was appointed to fix a price per unit, but had fixed a charge upon the maximum demand system. A sub-committee of the Electricity Committee has the matter in hand.

ACCRINGTON: *Electrical Exhibition.*—The Electrical Exhibition promoted by the Corporation Electricity Department was opened in the Town Hall on Monday.

ARGENTINE: *Monte Video: Tramway Amalgamation.*—The *Review of the River Plate* states it is rumoured that negotiations are being carried on for the amalgamation of the electric tramway companies in Monte Video.

Buenos Aires: Telephone System.—The following also appears in the *Review of the River Plate*:—"The Buenos Aires Municipality is said to be studying a project for the municipalisation of the telephone service. We do not expect anything to come of it, and it will be best for the public if nothing does. The Buenos Aires Municipality has not shown itself an expert in any of the public services to-day under its direction."

AUSTRALIA: *Melbourne: Dust Destructor.*—Excellent progress has been made with the construction of the City electricity works and refuse destructor, which, it is believed, will be ready for use by the end of this month, says the *Australian Mining Standard*. The plant will have a capacity of 150 tons per day, which allows for a slight increase upon the present average daily collection. The plant is of the Horsfall top-feed type, and consists of three units, each of two cells. Three Babcock & Wilcox water-tube boilers have been built in, and a start has been made with the clinker-crusher. The steam generated in the destructor furnaces will be utilised in the electric supply works adjoining, to which it is expected to prove worth about £2,000 per annum. The cost of plant and buildings is estimated at about £25,000.

BISPHAM: *Electric Lighting.*—Mr. J. W. Speight is to be asked his terms for acting as consulting engineer to the Council in connection with an electric lighting scheme.

BRITISH COLUMBIA: *Electric Power Supply.*—The British Columbia Electric Railway Company and the City of Victoria have, says the *Standard*, come to an agreement whereby the city agrees not to instal a power plant in competition with that of the company without offering to purchase the company's plant at a price to be fixed by arbitration. The company on its part agrees to reduce the cost of electric light, and to instal a power plant at Indian River, some fifty miles from Victoria, at a cost of about £300,000. The new arrangement is similar to that existing in Vancouver, and must be ratified by the ratepayers before coming into force.

COWDENBEATH: *Electric Lighting.*—The Council propose to apply for an electric lighting Provisional Order, and have asked the Fife Electric Power Co. to withdraw the name of Cowdenbeath from their proposed application for an order to supply in a number of places in this district.

FALKIRK: *Tramways.*—The extension of the Falkirk and District Tramway Co.'s lines to Laurieston, a distance of 1¼ miles, will be opened to-morrow. A parcels service will be carried on in connection with this extension.

FIFE: *Plant Extension.*—The Fife Electric Power Co. have ordered a 2,000-kw. turbo-alternator set for their power-house.

FRODINGHAM: *Electric Supply.*—Two schemes for erecting an electricity works having been placed before the Council, it has been decided to inquire into the advisability of applying for an electric lighting Provisional Order.

HALESOWEN: *Light Railways.*—The Board of Trade have confirmed the Halesowen Light Railways (Transfer, &c.) Order, 1909, transferring to a company the powers conferred upon the Rural District Council of Halesowen, by the Halesowen Light Railway Order, 1901, and by the Halesowen Light Railways (Extensions) Order, 1902, and amending those Orders.

HASLINGDEN: *Tramway Overhead Construction.*—At the Council meeting on Thursday, it was reported that several letters

Digitized by Google

had been received from Messrs. Dick, Kerr & Co. with regard to the tramway span wires. After some discussion it was resolved that the tangential suspension be dispensed with, and that ordinary mechanical ears be fixed.

KIRKCALDY: *Extension to Dysart.*—The agreement between the Kirkcaldy and Dysart Town Councils regarding the proposed extension of the Kirkcaldy tramways to Dysart has been approved by the latter Council. A tramway provisional order is to be applied for, and clauses will be inserted giving powers for the Kirkcaldy Council to supply electricity in Dysart.

LEEDS: *Heating Appliances on Hire.*—The Electricity Committee have decided to purchase a small stock of electric heating appliances for hiring out.

LONDON: *London County Council: Blackfriars Bridge Tramways.*—The Lord Mayor of London will officially open the widened Blackfriars Bridge on Tuesday, September 14th.

MANCHESTER: *Reduced Tramway Receipts.*—During the current financial year, which commenced on April 1st, the receipts from the Manchester Corporation tramways are less by £3,800 than those of the corresponding period of last year.

Theft of Tantalum Lamps.—The two men who were arrested on a charge of stealing tantalum lamps from Messrs. Drake & Gorham, Ltd., were sentenced to a month's and two months' imprisonment respectively by the city magistrates on Thursday.

NEW ZEALAND: *Wellington Tramways.*—According to the *Australian Mining Standard*, the Wellington Electric Tramway Co. carried 21,679,902 passengers during the year ended March 31st, an increase of 1,574,179 upon the number for the previous year. The net surplus on the year's business was £5,934, or £366 more than in the previous year.

CANADA: *Ontario: Electric Traction.*—It is announced that a new electric railway will soon be commenced from Morrisburg to Ottawa. A company has been incorporated with a capital of £200,000. The power plant will be located at Morrisburg and Billing Bridge, Ottawa. Another line contemplated, called the Belt Line Electric Railway, covers practically the same route; but the Corporation of Metcalfe, in Carleton County, proposes to give the right of way to the company that begins work first.

ROTHESAY: *Tramways Undertaking.*—Scottish tramway managers visited Rothesay last week. The company included Mr. R. S. Pilcher, of Aberdeen, and Mr. F. Coutts, of Paisley, secretary of the Scottish Tramway Managers' Association. The visitors were received by Mr. Archibald Robertson, manager, and Mr. H. H. Hill, resident engineer of Rothesay Tramway Company, and were shown over the local depôt at Pointhouse. A Paper by Mr. Peter Fisher, Dundee, on "Trackless Trolley Systems" was afterwards read, and a short discussion ensued on several matters of interest to tramway managers.

SOUTH SHIELDS: *Tramway Accounts.*—The total income from the Corporation tramways for the year to March 31st was £29,580, a decrease of £182 compared with the previous year. Traffic receipts were £2,867 less. Working expenditure amounted to £19,405, against £18,003 in 1908, and, after meeting interest and sinking fund charges, there is a net profit of £423. Total receipts per car-mile were 8·74d. The Tramway Manager complains of the high price charged for electrical energy, viz., 1·385d. per unit compared with an average of 1·225d. per unit paid by 60 similar tramway undertakings.

SPAIN: *Electrical Trade Prospects.*—A British Consular report states that although there are no satisfactory statistics available, the Consul's observations lead him to believe that British trade with the district is more than maintaining its relative position. In the heavy electrical trades the tendency is for orders to go elsewhere in preference to the United Kingdom, and this is probably due to the fact that foreign manufacturers were first in the field. He calls attention to the fact that the use of electricity is constantly extending, and that the key to the Spanish electrical trades is cheapness.

YORK: *Tramways.*—The reconstruction of the tramways for electric traction has been commenced by the contractors, Messrs. Dick, Kerr & Co., Ltd.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ARGENTINE.—The Santa Fe municipal authorities will shortly call for tenders for additional electrical machinery.

BRAZIL.—The municipal authorities at Corumba (Matto Grosso) invite tenders until October 5th for a number of public works, including an electric lighting installation.

BURSLEM.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £7,535 for the purposes of the electricity undertaking. The details of the loan are as follows:—Condenser, £1,200; foundations, £200; 600-kw. set, £3,155; foundations, £300; switchgear, £100; buildings, £1,000; boiler, £1,400; settings, £200; total, £7,535. There was no opposition.

GRIMSBY.—The Corporation invite tenders by Sept. 17th for two years' supply of cable. (See an advertisement.)

MANCHESTER.—It is proposed to make an application to the Local Government Board for sanction to borrow £50,000 for the purposes of the electricity undertaking. This amount is required principally for mains extensions.

TURKEY.—It is stated that a Commission has been appointed by the Turkish Ministry of Public Works to make investigations with a view to the establishment of electric lighting and power works in Constantinople. Estimates are to be prepared, and tenders invited for offers for the concession.

Miscellaneous

AUSTRALIA.—Tenders are invited by the Deputy Postmaster-General, Sydney, for a common battery switchboard at the North Sydney Telephone Exchange, and also for the supply and delivery of apparatus for use on subscribers' premises at North Sydney. Tenders by January 12th, 1910. Tender forms, specification, &c., may be obtained, and preliminary deposits paid, at the Commonwealth Offices in London, 72 Victoria Street, S.W.

FELIXSTOWE.—Tenders are invited for the supply of electricity meters. Particulars from the Council's consulting engineer, Mr. R. P. Wilson, 66 Victoria Street, London, S.W., and tenders to the Clerk by September 10th.

NETHERLANDS.—An agreement has been entered into between the Minister van Waterstaa and the Nederlandsche Buurtspoorweg-Maatschappij, of Utrecht, whereby the latter are granted a concession to construct and work an electric railway from Utrecht to Zeist *via* Bilt. The work of construction must be completed within two years from the date of the concession.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Adaptation of premises, Whitechapel Road, for branch of London & Provincial Bank. Builders, Fairhead & Son, Enfield, Middlesex.

S.W.—Skating rink, Wimbledon. Builders, Parkinson & Son, Blackpool.

PROVINCES.

ASHTON-UNDER-LYNE.—Hospital (£30,000). Town Clerk.

ATHERTON.—Additions to workhouse. The Guardians.

BELFAST.—Stores, G.N.R. (£8,000). Contractor, W. Dowling, Belfast.

BRIGHOUSE.—Additions to mill. Architects, Welsh & Nicholas, Museum Chambers, Halifax.

CHATHAM.—Additions Royal Sailors' Home. Architect, G. Bond, Chatham.

CLYDEBANK.—Library (£10,000). Surveyor, Town Council.

DARLINGTON.—Two shops, house, and warehouse, Tubwell Row (£1,115). Architects, J. J. Taylor & Minor, Post Office Chambers, Darlington.

DUNDEE.—The King's Cross Hospital is to be wired for electric lighting at a cost of £250.

ECCLES (LANCS).—School, Park Road, Monton (£12,500). Builders, William Nicholson & Son, Ltd., Prospect Saw Mills, Sheaf Street, Hunslet, Leeds.

HULL.—School, Sauer Street. H. Hirst, City Architect.

KEIGHLEY.—St. James' Church (£2,283). Architects, J. B. Bailey & Son, 3 Scott Street, Keighley.

LLANELLY.—School. Borough Engineer, Town Hall.

MANCHESTER.—Rink (£6,000). Architect, G. F. Ward, 71 Colmore Row, Birmingham.

NEWARK.—High School for Girls (£4,445). Architects, Brewell Baily, Nottingham. Builders, Brown & Son, Newark.

NEWCASTLE.—Technical Block, Rutherford College (£15,000). Builders, Middlemiss Bros., Newcastle.

NEWPORT.—Wesleyan Church. Architect, A. Lander, The Strand, Barnstaple.

PAISLEY.—New works for Arrol-Johnson Car Co., Ltd., Paisley.

SHEFFIELD.—Training college hall of residence (£11,890). Architects, Gibbs & Flockton, 15 St. James' Road, Sheffield.

SOUTHEND-ON-SEA.—Church school. Builder, J. C. Flexman, Southend.

SOUTH SHIELDS.—School, Langley Park. Builders, Sheriff & Son, South Shields.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

ECCLES.—The Council have accepted the tender of William Boby (London), at £275, for installation of water-softening and purifying plant at the electricity works.

INDIA.—The Lahmeyer Electrical Co., Ltd., have received an order from the Tata Iron & Steel Co., Ltd., for an electric power house.

LONDON: *Fulham.*—The Electricity Committee have provisionally accepted the tender (the lowest received) of the Stirling Boiler Co. at £2,377 for two boilers. They have further conditionally placed an order with the Underfeed Stoker Co., Ltd., at £556 for two underfeed stokers. The Electrical Engineer is to carry out the remainder of the work (the supply and fixing of motor for underfeed stokers, excavating and building necessary foundations, supplying and fixing additional steam and other piping, steam accessories, &c.), at a total estimated cost of £935.

SALFORD.—The Guardians of the Salford Union have accepted the tender of the Hart Accumulator Co., Ltd., for the renewal and maintenance of the storage battery of 110 cells installed at Culcheth Cottage Homes.

WIGAN.—The Electric Light Committee has considered the following tenders in connection with the extension to the electricity works:—Pipework and economisers, Tickle Bros., Wigan (accepted), £3,778; coal conveyor, Bennis & Co. (accepted), £2,050.

Mixed-pressure turbine with alternator and condensing plant at the Wigan station, and motor-generators at the Pemberton station:—British Thomson-Houston Co. (Curtis) (accepted for Wigan station), Wigan, £6,106; motor-generator, Pemberton, £2,242. James Howden & Co. (Zolley), Wigan, £6,286; motor-generator, £2,180. General Electric Co. (Belliss) (accepted for Pemberton Station), Wigan, £6,719; motor-generator, £1,980. British Westinghouse Co. (Parsons), Wigan, £6,882; motor-generator, £2,027. Musgrave & Co. (Zeelly), Wigan, £6,875; motor-generator, £2,075. Crompton & Co. (Belliss), Wigan, £7,077; motor-generator, £2,142. Lancashire Dynamo Co. (Belliss), Wigan, £7,490; motor-generator, £2,561. Brush Engineering Co. (Parsons), Wigan, £6,492 10s.; motor-generator, £1,811. Phœnix Dynamo Co. (Rateau), Wigan, £6,628; motor-generator, £1,910. Willans & Robinson (Parsons), Wigan, £6,855; motor-generator, £1,647 15s. All the foregoing were for 1,000 kw. except the Brush Engineering Co., who offered a 750 kw.

Condensing Plant:—British Thomson-Houston Co. (accepted), £1,068; Jas. Howden & Co., £1,247; General Electric Co., £1,100; British Westinghouse Co., £1,400; Musgrave & Co., £1,057.

Switchboards:—British Thomson-Houston Co. (accepted), £2,470; Crompton & Co., £2,499; Spagnoletti, Ltd., £2,604; Dorman & Smith, £2,631 15s.; Electric Construction Co., £2,654 10s.; Switchgear Co., £2,677 15s.; General Electric Co., £2,796 17s.; Lancashire Dynamo Co., £3,076. The following were not to specification:—British Westinghouse Co., £1,994; Johnson & Phillips, Ltd., £2,061; Ferranti, Ltd., £2,197 15s.; Siemens Bros., £2,394. The following were not fully quoted:—Whipp & Bourne, £1,272; Cowans, Ltd., £2,178; Drake & Gorham, Ltd., £800; Cox, Walker, Ltd., £833; Dick, Kerr & Co., Ltd., £2,788; Union Electric Co., Ltd., £2,080 15s.; Lahmeyer Electrical Co., Ltd., £2,095 1s. The acceptance of the foregoing tenders is conditional upon the sanction of the Local Government Board being obtained to the proposed extensions.

WOODESON BOILERS.—Some very large and important orders have recently been placed with Messrs. Clarke, Chapman & Co. for "Woodeson" boilers. Among them are the following:—Three large boilers for Bury Corporation, one large boiler for the Admiralty, four large boilers for the new coke oven plant for Messrs. Strakers & Love, making the sixth repeat order from this firm; a large boiler for the Yorkshire Electric Power Co., this being repeat order due to the success of a similar boiler installed in that station in the early part of this year; a further repeat order for two boilers for the power station in Naples, this making the third repeat order. Also important orders for boilers for South Africa and Japan.

COMPANIES' MEETINGS AND REPORTS

AMERICAN TELEPHONE & TELEGRAPH CO.—From January 1st to July 31st there is a net surplus of £760,000, after payment of the regular quarterly dividends of 8 per cent. per annum. This is about £60,000 more than in the corresponding period of last year, despite the fact that depreciation has been charged against revenue monthly instead of being provided by an extraordinary charge in December.

DUMBARTON BURGH & COUNTY TRAMWAYS CO.—The profit for the year to July 31st last, after providing for interest on debenture stock, amounts to £6,192, to which has to be added the balance brought forward, making £7,520. From this has to be deducted the 6 per cent. preference dividends, leaving £3,020, which the directors recommend should be carried forward. Under arrangement with the Corporation of Glasgow, the company have since December last operated the short section of the Corporation lines between the end of the company's line at Dalmuir and the Corporation's terminus at Dalmuir. £80,000 five per cent. debenture stock was issued in October, 1908, to provide the funds required for the completion of the tramways.

WOLFRAM-LAMPEN A.-G., AUGSBURG.—The following notes relating to the third year of business of this company are taken from the *Electrotechnischer Anzeiger*. A factory in Bavaria was taken over at the beginning of the year, and in consequence of increasing business, the factory at Lechhausen is to be enlarged. Partly in consequence of the introduction of several new processes, the past year, after meeting all charges, and making provisions for depreciation, closes with a loss of approximately £10,150, which will be covered by the reserve fund. The latter will then stand at approximately £5,350.

MERSEY RAILWAY CO.—The report for the June half-year shows total receipts amounting to £53,227, compared with £51,783 for the corresponding period of last year, whilst working expenses, exclusive of pumping, ventilation, and lifts, were £30,810, against £33,075. Pumping, ventilation and lifts incurred expenditure amounting to £3,659, compared with £4,070 in the corresponding period of 1908.

At the meeting last week, the report and accounts were adopted. Mr. James Falconer, M.P., chairman of the company, drew attention to the fact that the net result for the half-year was a gain of £4,119. An interesting comparison, he said, was between the past half-year and the last half-year under steam traction, electric traction having been adopted in May, 1903. The number of passengers carried during the last half-year of steam working was 2,800,000, and during the past half-year 5,800,000, showing an increase of three millions, or over 104 per cent. Season ticket journeys had improved from 512,980 to 1,381,467, an increase of 169 per cent. The receipts of the company had gone up from £29,470 during the last half-year of steam to £53,228 in the past half-year.

ABERDEEN SUBURBAN TRAMWAYS CO.—The accounts for the half-year ended July 31st show a profit of £775, making, with the sum carried forward from last accounts, £2,193. The directors propose adding £1,000 to the renewal and depreciation account, which will then stand at £5,000; the payment of a dividend of 2 per cent. for the past year on the paid-up capital, and, after meeting directors' fees, carrying forward £527.

ISLE OF WIGHT CENTRAL RAILWAY CO.—At the annual meeting last week, it was stated that two proposals had been placed before the directors for the conversion of the lines to electric traction. No definite offer, however, had been made, and the directors did not attach much importance to the negotiations. They would, however, give full consideration to any scheme which came before them.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The report for the half-year to June 30th shows a substantial improvement. The net revenue from investments and rents, after deducting general expenses and interest, amounted to £62,879 10s.; the net income from the operation of the power-house was £40,659; and the interest on £775,000 4½ per cent. power-house debentures amounted to £17,437, leaving a surplus from the power-house of £23,222, and a gross revenue of £86,101 10s. The service of the £1,000,000 5 per cent. prior lien bonds required £26,349; the service of the £2,808,000 4½ per cent. bonds required £66,589; and the payment under the guarantee on Metropolitan District Railway Assented Extension preference stock amounted to £9,403 12s., making the total charges £102,341. The net revenue was therefore insufficient to meet the half-yearly charges by £16,240. To cover this deficit, Messrs. Speyer have purchased from the company, in accordance with the agreement of April 7th, 1908, £10,700 4½ per cent. bonds of 1933 and £16,050 6 per cent. income bonds for the sum of £16,050. This deficit is apparently larger by £4,403 10s. 9d. than that shown in the first revenue account submitted in February last. That account, however, includes more than one half-yearly dividend on the company's holding of shares in the Tube companies, and a large part of the fixed charges had been charged to capital under the scheme of readjustment. The income from investments for the six months shows an increase of £22,065, or about 40 per cent., over that in the previous half-year. This result has been obtained notwithstanding the fact that the three Tube companies from which

Digitized by Google

this company receives dividends have set aside for contingencies and renewals out of the net earnings of the last six months the following amounts:—Baker Street & Waterloo Railway Company, £4,000; Great Northern, Piccadilly & Brompton Railway Company, £6,000; Charing Cross, Euston & Hampstead Railway Company, £3,000—£13,000. The Metropolitan District Railway Company have also set aside for renewals out of the net revenue of last half-year the sum of £10,000. The meeting is on September 21st.

NEW COMPANIES

INTERNATIONAL ELECTRIC TRANSPORT & ENTERPRISE CO. OF ALSACE-LORRAINE.—Registered on August 21st, with a capital of £200,000 in 195,000 preferred shares of £1 each, and 100,000 deferred shares of 1s. each, to undertake and develop electric carriage and other enterprises in Alsace-Lorraine and elsewhere, and to carry on the business of constructors of electric tramways and railways, motor vehicles, tunnels, bridges, and roads, carriers of pasengers and goods, &c. Registered office: 3 East India Avenue, E.C.

HAMMERTON & CO.—Registered on August 18th, with a capital of £5,000 in £1 shares, to promote, construct, equip, maintain, and work railways and tramways in the U.S.A. or elsewhere, and to carry on the business of rolling-stock manufacturers, engineers, shipbuilders, carriers, &c. Registered by Cox & Lafone, 17 Tower Royal, E.C.

MALCOLM & ALLAN.—Registered in Edinburgh on August 20th, with a capital of £20,000, to carry on in the United Kingdom, or elsewhere, the business of contractors, engineers, builders, plumbers, metal founders, electricians, constructors of, and dealers in, motors, motor-cars, and motor-boats, suppliers of electricity or gas for the purposes of light, heat, and motive power, &c. Registered office: 499 Eglington Street, Glasgow.

MISCELLANEOUS CITY NOTES

COMPANY STRUCK OFF REGISTER.—The London-Provincial Electrical Co., Ltd., has been struck off the register of Joint Stock Companies.

UNITED ELECTRIC CAR CO.—A dividend of 2½ per cent. for the year to June 30th is recommended upon the ordinary shares.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—Warrants for interim dividends, payable the 31st inst., on the company's 7 per cent. cumulative first preference shares and 6 per cent. cumulative second preference shares, for the half-year ended June 30th, 1909, have been posted.

APPOINTMENTS AND PERSONAL NOTES

The Governors of the Electrical Standardising, Testing, and Training Institution have appointed Dr. Alexander Russell, M.A., D.Sc., M.I.C.E., Principal of the Institution, in succession to the late Mr. Hugh Erol Harrison.

Dr. Russell took the degree of M.A. at Glasgow University in 1882 with first-class honours in Mathematics and Natural Philosophy. In the same year he obtained the first prize in Lord Kelvin's Senior Natural Philosophy Class. At Cambridge he was Fourteenth Wrangler in 1885. When Faraday House was started in 1890 he was appointed Lecturer on Applied Mathematics and Head of the Physical Laboratory Department. Since his appointment he has written more than fifty papers on subjects connected with electrical engineering. He has also written an advanced treatise on "Alternating Currents," a treatise on cables, two lengthy serials, one on "Electrical Engineering," and the other on "Electric Heating and Lighting," and he has translated Prof. Buchetti's work on "Engine Tests and Boiler Efficiencies." For five of his Papers to the Electrical Engineers he has received premiums, and six of his Papers have been published in the *Philosophical Magazine*. Dr. Russell's name is perhaps best known in connection with the grading of electric cables. He was the first to explain what was meant by the capacity of polycore cables, and in conjunction with Mr. G. F. C. Searle, F.R.S., devised an accurate definition of the capacity between two cores. In 1901 he devised "Russell's test" for measuring the insulation resistance of a network of mains, and in 1903 he devised a rapid method of measuring the mean spherical candle-power of lamps which has come into extensive use, and is embodied in the Russell-Leonard photometer. At the beginning of the present year he read a Paper to the Physical Society, giving for the first time the complete solution of the important problem of the "skin effect" in concentric mains, which was first discussed by Maxwell. The solution was given in terms of certain new functions which he called the ker and kei functions. The computation of tables of these functions has been undertaken, and is rapidly approaching completion. Kelvin's tables for ber and bei functions have also been recomputed. He has also this year, in conjunction with Mr. Arthur Wright, the well-known electrical engineer, been engaged with considerable success in perfecting methods for solving algebraical equations and doing other mathematical operations by electricity. Last June Dr. Russell read a Paper to the Royal Society, in which he showed how the attractions or repulsions of electrified spherical conductors could easily be computed when they were close together.

Mr. J. H. Shepherd, Manager of the Dundee, Broughty Ferry & District Tramways Co., Ltd., has been appointed Manager of the Dunfermline & District Tramways Co., Ltd.

On Thursday last, the marriage of Mr. H. M. Hobart with Miss E. S. Walpole was celebrated at Holy Trinity Church, Beckenham.

Mr. Karl von Krogh, in whose hands the management of a number of important shops of the British Westinghouse Co.'s Works at Trafford Park has been for several years, is leaving that company to set up as a consulting engineer in Norway.

Mr. H. G. White, for eight years Chief Engineer to the Sterling Telephone & Electric Co., Ltd., has resigned that position to take over the management of the Electrical Department of the Soho Scientific Instrument Co., St. Anne's Court, Wardour Street, W. On leaving the Sterling Co., Mr. White was presented with a pair of silver candlesticks on behalf of the directors, and a handsome inlaid rosewood clock, suitably inscribed, from the staff.

The Ilkeston Corporation require a manager to take charge of the electricity and tramways departments. Salary, £200 per annum. Applications to the Town Clerk by September 6th.

Colonel R. C. Hellard, C.B., has been appointed technical assistant to the superintendent for one year; Lieutenant E. C. Fishbourne, R.E., a technical assistant for one year; and Mr. Mervyn Chute a temporary assistant, in the London Traffic Branch of the Board of Trade.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £60 10s. to £61 per ton (last week, same).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The liquidator in the winding up of the Electric Timber Seasoning & Preservation Co., Ltd., has been released.

A meeting of the Deep Leads Electric Transmission Co., Ltd., will be held at 20 Copthall Avenue, London, E.C., on September 22nd, at 1.30 p.m., for the purpose of hearing the liquidator's account of the winding up.

E.M.F. MFG. CO.—Mr. O. H. Bishop, late Sales Manager to the Edison & Swan United Electric Lighting Co., Ltd., has joined this company as Joint Managing Director. The firm have also acquired the electrical business recently carried on by Mr. T. H. Satchwell, Victoria Works, Walsall, and the E.M.F. Mfg. Co. has now been registered under the Companies Act.

SIEMENS "TANTALUM" OUTING.—The staff and employees of Messrs. Siemens Bros. Lamp Dept. held their annual beanfeast at Clacton-on-Sea on Saturday, August 21st. At the luncheon at the Clacton Palace, Mr. W. H. Le Marechal, the Works Manager, proposed the toast of the kindred firms, Messrs. Siemens Bros. & Co. and Messrs. Siemens Bros. Dynamo Works, Ltd., in the absence of Mr. Barfield, the Manager of the Sales Dept. The toast was seconded by Mr. A. B. Holmes.

ROBERTSON AND OSRAM ATHLETIC CLUB SPORTS.—The members of this club held their fourth annual sports on Saturday last at Wood Lane, Shepherd's Bush. The relay race for the Wilson challenge cup was again won by the General Electric Co. Athletic Club, "London." One of the chief items of the day was the marathon race from Pinner to the ground, which was won by A. Bailey. A tug-of-war between the Osram and Robertson works was won by the latter. Mr. C. Wilson, Mr. C. J. Robertson, and Mr. E. G. Sheppard officiated as judges, and the prizes were presented by Mrs. C. Wilson.

Telegraph Traffic and Movements of Cable Ships.—The opening to international traffic of the new German cable from Borkum to Teneriffe took place on August 26th. This is the first section of the system of German cables to South America. The laying of such a long section was necessitated by the successful opposition of the Eastern telegraph companies to a landing being granted to the new enterprise at Madeira. Direct communication between Saigon and Bangkok was down on August 24th, messages having to be diverted *via* Obone subject to delay, but the line was again restored on August 26th. The line between Bagdad and Bassorah also ceased operating on the 24th ult., and three days later communication with Rabat and Mogador was interrupted. On the 27th ult. repairs were effected to the cable between Ceuta and Tangier. On August 30th also the Melilla-Chafarinas cable was again working. The Western Union Telegraph Co. has repaired one of its cables. C.S. *Cambria*, of I.C. & M. Co., completed repairs of the New York-Guantanamo cable of C. & S.A. Tel. Co. on August 6th. The Australian Commonwealth Government is about to take steps to enable it, in the event of war, to take control of the cables landing on its territory.

MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE meeting of the British Association for the Advancement of Science was inaugurated at Winnipeg on Wednesday last week by the delivery of the Address of the President, Sir J. J. Thomson, who reminded his audience that this was the third meeting held in Canada. In 1884 the Association met in Montreal, and in 1887 at Toronto.

Comparing the educational system in force at the Colonial universities with that which prevails in the older English universities, Sir Joseph said that he had come to the conclusion that there is a good deal in the latter system which they had been wise not to imitate. The chief evil at Cambridge which they had avoided was, he was convinced, the excessive competition for scholarships which confronts the students at almost every stage of their education. The colleges in the University of Cambridge alone, he said, give more than £35,000 a year in scholarships to undergraduates, and the result was that preparation for these scholarships dominated the education of the great majority of the cleverer boys who came to these universities. The preparation for the scholarship too often meant that about two years before the examination the boy began to specialise, and from the age of sixteen did little else than the subject for which he wished to get a scholarship; then, on entering the university, he spent three or four years studying the same subject before he took his degree. The effect of studying one subject, and one subject only, for so long a time was too often to dull his enthusiasm for it, and he began research with much of his early interest and keenness evaporated. Moreover, the premature specialisation fostered by the preparation for these scholarships injured the student by depriving him of adequate literary culture, and while, when it extended, as it often did, to specialisation in one or two branches of science, it retarded the progress of science by tending to isolate one science from another, for the boundaries between the sciences are arbitrary, and tend to disappear as science progresses. The tendency which had developed in some quarters to discourage the use of mathematics in physics was, in Sir Joseph Thomson's opinion, much to be regretted. While he did not urge that the physicist should confine himself to looking at his problems from the mathematical point of view (on the contrary, he thought a famous French mathematician and physicist was guilty of only slight exaggeration when he said that no discovery was really important or properly understood by its author unless and until he could explain it to the first man he met in the street), yet two points of view were better than one, and the physicist who was also a mathematician possessed a most powerful instrument for scientific research with which many of the greatest discoveries had been made. He also pleaded for a greater study of physics by mathematicians in the interest of pure mathematics. Pure mathematicians had been indebted to the study of concrete problems for the origination of some of their most valuable conceptions. As an illustration of the power of the concrete in stimulating the mind, Sir Joseph gave the instance of one of his pupils who knew little and cared less about mathematics, but happened to be enthusiastic about billiards. When they were reading that part of mechanics which dealt with the collision of elastic bodies, however, this student, who had never before regarded mathematics as anything but a means of annoying innocent undergraduates, now saw what important results it could obtain, and he became enthusiastic about it, developed very considerable mathematical ability, and, though he had already wasted two out of his three years at college, took a good place in the Mathematical Tripos.

The speaker next referred to the great educational value of original research in any branch of experimental science. Students beginning research in experimental physics always showed quite remarkable improvement in judgment, independence of thought and maturity after a year's research work. It developed qualities which were apt to atrophy when the student was preparing for examinations. He suggested that the practice in many universities of making special provision for the reception of students from other universities who wished to do original research or to study the more advanced parts of their subject should extend to students at an earlier stage in their career. He favoured especially the interchange of students between the universities in the Mother Country and those in the Colonies.

Sir Joseph then proceeded to give a short account of some of the more recent developments of physics, and the new conceptions of physical processes to which they had led, in the course of which he said that the great advantage of the electrical methods of the study of the properties of matter is due to the fact that whenever a particle is electrified, it is very easily identified, whereas an uncharged molecule is most elusive; and it is only when these are present in immense numbers that we are able to detect them. The smallest quantity of unelectrified matter ever detected is probably that of neon, one of the inert gases of the atmosphere, and the neon in $\frac{1}{9^{1}0}$ of a cubic centimetre of air would only occupy at atmospheric pressure a volume of half a millionth of a cubic centimetre. But in this small volume there are about ten million million molecules. Now the population of the earth is estimated at about fifteen hundred millions, so that the smallest number of molecules of neon we can identify is about 7,000 times the population of the earth. In other words, if we had no better test for the existence of a man than we have for that of an unelectrified molecule, we should come to the conclusion that the earth is uninhabited. On the other hand, we can by the electrical method, even better by the cloud method of C. T. R. Wilson, detect the presence of three or four charged particles in a cubic centimetre. Rutherford has shown that we can detect the presence of a single α particle. The particle is a charged atom of helium; if this atom had been uncharged, we should have required more than a million million of them, instead of one, before we should have been able to detect them.

The speaker then outlined the progress that had been made in discovering what the structure of electricity is, and towards formulating a molecular theory of electricity, which would be a starting-point for a theory of the structure of matter. The amount of energy which is stored up in ordinary matter in the form of the electrostatic potential energy of its corpuscles is, he said, not generally realised. Assuming that each atom of a substance contains only one corpuscle, the energy due to the corpuscles in a gramme of hydrogen would be 48×10^{16} ergs, or 11×10^{9} calories. This is more than seven times the heat developed by one gramme of radium, or than that developed by the burning of five tons of coal. This energy is, fortunately, kept fast bound by the corpuscles; if at any time an appreciable fraction were to get free, the earth would explode, and become a gaseous nebula.

The matter of which I have been speaking so far, Sir Joseph continued, is the material which builds up the earth, the sun, and the stars; this matter occupies, however, but an insignificant fraction of the universe; it forms but minute islands in the great ocean of the ether,, the substance with which the whole universe is filled. On this earth we are dependent from minute to minute upon the gifts of the sun which are conveyed to us by the ether. It is to the sun that we owe not merely night and day, springtime and harvest, but it is the energy of the sun, stored up in coal, in waterfalls, in food, that practically does all the work of the world. The heat received by the earth under a high sun and a clear sky is equivalent, according to the measurements of Langley, to about 7,000 horse-power per acre. Though our engineers have not yet discovered how to utilise this enormous supply of power, they will, I have not the slightest doubt, ultimately succeed in doing so; and when coal is exhausted and our water-power inadequate, it may be that this is the source from which we shall derive the energy necessary for the world's work. When that comes about, our centres of industrial activity may perhaps be transferred to the burning deserts of the Sahara, and the value of land determined by its suitability for the reception of traps to catch sunbeams.

On the electromagnetic theory of light, now universally accepted, the energy streaming to the earth travels through the ether in electric waves; thus practically the whole of the energy at our disposal has at one time or another been electrical energy. The ether must, then, be the seat of electrical and magnetic forces.

An interesting speculation (or, to meet a complaint made by Sir Oliver Lodge in Tuesday's *Times*, we should rather say, deduction) as to the nature and properties of the ether, based on the most recent investigations and research work, which followed, occupied the greater part of the address. The concluding portion of Sir Joseph Thomson's address reviewed briefly the development of the study of radio-activity since its discovery by Becquerel.

Prof. E. Rutherford, President of Section A (Mathematics and Physics), spoke on the present position of the atomic theory in physical science, and discussed the various methods that have been devised to determine the values of certain fundamental atomic magnitudes.

Prof. H. E. Armstrong, President of the Chemical Section, in the course of his address, criticised the speculations of the school of Ostwald, who, he said, "had charged his test-tubes with ink instead of with chemical agents, and by means of a too facile pen has enticed chemists the world over into becoming adherents of the cult of ionic dissociation—a cult the advance of which may well be ranked with that of Christian science, so implicit has been the faith of its adherents in the doctrines laid down for them, so extreme and narrow the views of its advocates. At last, however, the criticism which has been far too long delayed is being brought to bear, and the absurdity of not a few of the propositions which the faith entails is being made evident; it is to be hoped that we shall soon enter on a period in which common sense will once more prevail; that ere long an agreement

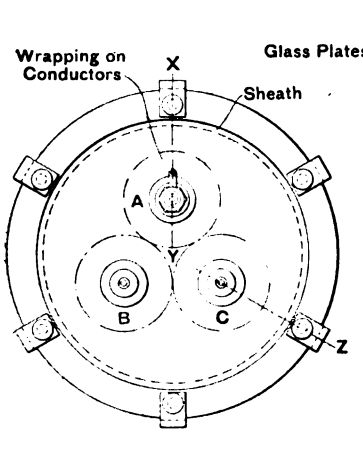
Digitized by Google

will be arrived at, both as to the conditions which determine it and as to the nature of chemical change in general. The lesson we shall have learnt is one of no slight import if it but teach us the ever-present need of questioning our grounds of belief, if it serve to bring home to us the danger of uncontrolled literary propagandism in science, if it but cause us always to be on our guard against the intrusion of authority and of dogmatism into our speculations."

Prof. Armstrong also expressed his antagonism to the widely accepted hypotheses explaining the phenomenon of radio-activity, considered the classification of the elements, discussed the subjects of valency, chemical change, and the nature of solutions, and then passed to organic and vital chemistry. A page of his address viewed "the revolt of women against their womanhood," from a scientific standpoint, and he concluded his address by deploring the present ideas of education, which, he said, "are in almost as inchoate a state as they were in 1885." He regretted that the days of popular lectures are past, that practically nothing is done to train the public mind, and that school science is in no way effective. On the neglect of chemistry he was particularly emphatic. An approach of interests, he said, was required between the chemist and the engineer. In Germany the chemist and the engineer had been placed on an equality and required to work together, with results which were altogether satisfactory. We needed to adopt a similar practice. Any attempt to fuse the two into one would meet with failure, as they were called upon to work from different points of view; they must be in sympathy, and understand one another, but their work was complementary. Our future engineers should study chemistry, and chemists should study engineering, in order that they may understand one another and work together—not in order that they may supplant one another.

In his address to Section G (Engineering), Sir William White summarised the most important services which the engineer has already rendered to the Dominion of Canada. His address was divided into the following sections: Railways, Inland Navigation, Shipping on the Great Lakes, The St. Lawrence Ship Canal, Water Power, Oversea Trade and Transport, the Marine Steam Turbine, and An Imperial Navy. We quote from the section dealing with Water Power:—

Canada has unrivalled resources in water-power, and its extent and possible utilisation have been made the subject of investigation by engineers for many years past. Exact knowledge of the total power represented by the water-falls and rapids of the Dominion is not available, nor can any close estimate be made of the power which may be employed hereafter in factories, mills, or industrial processes, because profitable employment obviously depends upon commercial considerations, which must be governed largely by the localities in which water-power may be found, and the cost of works and of transmission of energy to places where it can be utilised. It has been estimated that on the line from Lake Superior through the chain of lakes and rivers leading to Niagara and thence through the St. Lawrence to the sea, eleven millions horse-power may be developed.* Mr. Langelier has estimated that in the Province of Quebec the water-power aggregates more than eighteen millions horse-power; other provinces all possess large resources of the same kind as yet untouched. The most striking example of the utilisation of water-power is that on the Niagara River. The three companies whose works are near the Falls on the Canadian side have provided for a total ultimate development of over 400,000 horse-power, and a fourth establishment lower down the river, intended chiefly for the use of Hamilton, is to develop 40,000 horse-power. In the construction of the works, in the electric generating plant, the arrangements for transmitting power over long distances, and other features of importance, remarkable engineering skill and daring have been displayed. American capital and enterprise have had much to do with these undertakings, as they have with many other important Canadian enterprises, but it may be hoped that British capital will keep its lead and be freely employed in the development and utilisation of all the resources of the Dominion, including that magnificent asset, its water-power. The applications of water-power are already very numerous, including not merely the creation of electrical energy, and its use, for lighting and power in towns and factories situated at considerable distances from the Falls, but for manufactures and industrial processes carried on near the Falls. Amongst these manufactures, that of aluminium and carbide of calcium may be mentioned, while paper and pulp-mills and saw-mills constitute important industries. Great advances have been made in the transmission of electrical power over long distances, and very high pressures are being used. Electric traction on railways and tramways also derives its power from the same sources, and is being rapidly developed. In 1901 there were 553 miles of electric railways, and in 1907 815 miles.



* The *Times Financial Supplement*, April 2, 1906, contains a valuable article on this subject, from which many of the above figures are taken.

AMONG the few Papers read before Section G which were of interest to electrical engineers was the following, which we publish in a slightly condensed form:—

The Distribution of Dielectric Stress in Three-Phase Cables

By Professor W. M. THORNTON and O. J. WILLIAMS.

In solving the problem of ascertaining approximately the voltage gradient at any point in the cross-section of a three-core cable as used for three-phase currents at any time during the cycle, the authors employed the stream-line method used by Professors Hele-Shaw and Hay for the solution of otherwise indeterminate problems in the distribution of magnetic fields of force. They pointed out that in an electrostatic case it is only necessary to replace permeability by the dielectric constant, so that the relation given by them that the permeabilities of two adjacent areas of the stream-line film were in proportion to the cube of their thickness applies directly to dielectric constants also. Since the conductors have in effect an infinite induction constant, the form of the field will be the same whatever the dielectric constant of the insulation, provided that this is small and the same everywhere.

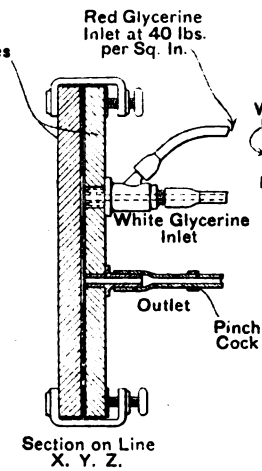


Fig 1.—Slide for Three-Phase Cables.

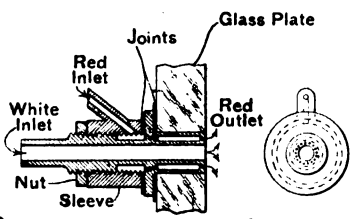

Fig. 2.—Injector Nozzle for White Glycerine with Red Stream Lines.

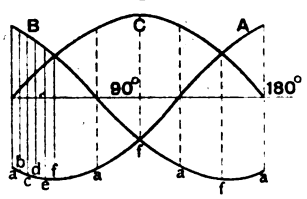

Fig. 3.—Relation of Diagrams to the Three Phases.

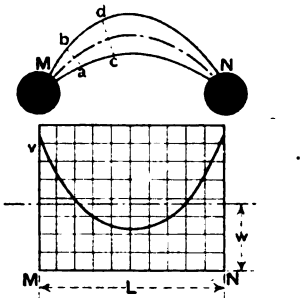

Fig. 4.—Change of Intensity of Stress along a Line of Force.

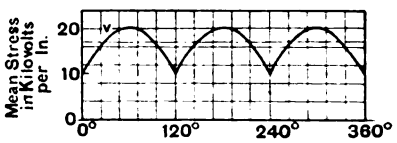

Fig. 5.—Triple Frequency Variation of Intensity of Stress between Conductors.

Two circular glass plates, 6 in. in diameter and 0·5 in. thick, were prepared, and three holes were drilled through one of them 3 in. apart, and equidistant about the centre, as shown in Fig. 1. Into two of these, brass nozzles were cemented, to which india-rubber pressure tubing was attached, fitted with screw-pinch cocks. For the third, a special injector was made, illustrated in Fig. 2. The other plate was then coated with paraffin wax, planed and cut to represent the section of a three-phase cable. The cavities cut in the wax coincided with the nozzle openings in the first plate. An annular cavity surrounding all represented the sheath. The plates being clamped together, with a ring cut from a sheet of thin drawing-paper forming a joint, red and white glycerine were injected by the one nozzle, and allowed to flow away by the other two. Part of the liquid entered the annulus, and, passing round the side, escaped by way of one of the latter two nozzles or sinks; no liquid escaped from the edges of the slide.

The algebraical sum of the flow between the three openings is zero, whatever the total flow may be. The distribution of the lines of force in an actual three-phase cable does not depend

Digitized by Google

upon the magnitude of the voltage applied. In the same way the lines of flow in the model do not depend upon the total quantity passing, but only on the relation between the flow in the two sinks. (In the analogy between hydrodynamic and electrostatic or magnetic problems, velocity of liquid flow is comparable with the intensity of stress.) If the sinks are adjusted to have the same discharge from each, we have the electrical case of one wave at maximum voltage above the neutral, the other two equal and opposite to it in phase, and each one-half of it in magnitude, that is case *f* (Fig. 3). If one is closed, all the liquid entering leaves by the other, and we have case *a*. These two cases are the limits, and recur at intervals of 30° continually. Four intermediate positions were chosen, corresponding to phase positions of 0°, 6°, 12°, 18°, 24°, and 30° on one of the phases—that marked C. The flow of glycerine was adjusted by the screw clips on the discharge nozzles to an accuracy of three drops in 100.

It was not possible to obtain photographs of the stream-lines through the plate holding the nozzles, and there was therefore a film of wax between the red stream-lines and the camera. The diagrams of Fig. 6 were prepared by projecting the photographs upon large sheets of drawing-paper, and sketching in the lines by hand. The case represented is that of a high-tension cable with wrapping and filling of the same dielectric constant. It corresponds most nearly in practice with the extra high-pressure cable for 6,600 volts; area of complete strand, 0·125 sq. in.; diam. of strand, 0·46 in.; dielectric between conductors, 0·24 in. on each; dielectric between conductor and sheath, 0·48 in. on each. As the mean dielectric stress along a line of force is equal to the total difference of potential between its end divided by its length, the diagrams give both the direction and the mean intensity of the stress.

In order that the stress at any point or the gradient at different points along a line may be found, it is necessary to measure the distance between adjacent lines. The gradient along the centre line M N, in Fig. 4, is inversely proportional to the distances *a b*, *c d*, and to find the exact stress at any point along it, the average stress must first be found—that is, V_{w}/L denoted by *w* in the diagram; at *c d*, for example, the stress per inch $= (S/c\ d) \times x\ w$, where S is the mean space of the lines apart. As in all cases, where circular conductors are used, the stress is greatest at the circumference of the conductor. The figures *a* to *f*, Fig. 6, show how the stress changes during the cycle, and the authors also gave a set of tables giving the mean stress along lines starting at equal distances apart around each conductor.

The dielectric surrounding each conductor carries a stress which rises and falls in a sine wave if the applied voltage is sinuous. The nature of the alternation and the way in which the centre line of intensity of stress in the cable swings round is readily seen by the polar diagrams in Fig. 7, corresponding respectively to the diagrams of Fig. 6. The radius vector of the curve around each conductor is the mean stress along the line, starting from the surface of the conductor in that direction. The feature of these polar curves is the very sharp manner in which the mutual action of the charges on conductors and sheath is developed around the surface of the conductors, suggesting harmonic disturbance there, at least in the interpolar space. In the first diagram of Fig. 6 the conductors A and B are at equal potentials above and below zero, and C is at zero. As the pressure on C rises the stress in the medium rapidly increases in the neighbourhood of the line joining the centres of A and C, and, to a less extent, of B and C; and by a transition which is readily followed in the diagrams, the stress between A and B falls, whilst that between A and C rises, until it is equal to the former. During a period these states occur, so far as the conductor A is concerned, in the order *a*, *b*, *c*, *d*, *e*, *f*, followed by *e*, *d*, *c*, *b*, *a*, but with the diagrams reversed. At the end of this set the conductor C will be in exactly the same state as A was at the start, and the sequence is repeated for C, and then for B, making 60 diagrams for the complete period. It will be noticed that although the pressure in the phases, measured from zero, reaches a maximum in the order of A, B, C, as in Fig. 3, the position of maximum intensity of stress, irrespective of its direction, rotates backwards at twice the frequency of the circuit. For example, taking the position of 30° on the conductor A, that is the line joining the centres of conductors A and C, the variation of mean intensity of stress along a line of force starting at this point is plotted in Fig. 5. There are three maximum and three minimum conditions of stress in one alternation, giving in effect a triple frequency harmonic with a disturbance of higher frequency. The same is found with smaller amplitude at 60° and other points. The stress between a conductor and the sheath, however, is a rectified wave at the supply frequency.

In order to use the section to the best advantage, the dielectric should carry a constant stress throughout its thickness. It is possible to do this in single-phase cables by suitably grading the insulating material, so that the dielectric constant decreases outwards from the conductor. This is impossible in three-phase cables, but by the use of "clover-leaf" sections for the conductors, the stress may be made much more uniform than in the case of circular sections. The efficiency of a cable, so far as its manufacture is concerned, may be expressed as the maximum kilovolt-amperes which it will carry per pound weight of insulation per yard run. Since the stress by which electrical energy is transmitted along a cable is in the insulation, and not in the copper, the most efficient cable is that in which the mean volts per inch per square inch of section of insulation is greatest. The diagrams of Fig. 8 show the greater economy of section, apart from questions of manufacture, in the "clover-leaf," as compared with the circular conductor. The polar curves for the clover-leaf case would, however, show more sudden changes at the corners of the conductors.

Under most conditions of working the copper loss is much greater than that from dielectric hysteresis, and the heat so produced expands the conductor and insulation equally in all directions, but the dielectric loss in a lightly-loaded cable is not equally distributed over the section. Assuming that it varies as the square of the voltage gradient at any point, curves of heating might be drawn by squaring the polar ordinates in Fig. 7. The actual heating would be even less uniform than the resultant curves might indicate, for, as shown in Fig. 4, the stress varies along a line of force possibly by as much as 3 to 1. There are then very localised, and comparatively small parts of the section between conductors when these are circular, in which the heating may well be from eight to ten times greater than that between a conductor and the sheath. How far this inequality of heating affects the life of a cable cannot be said until there is available information as to the comparative lives of cables with circular and other forms of conductors, but otherwise under the same conditions. What may be more important is that the ageing of the insulation will certainly be very unequal; and so far as the tendency to powdering is concerned, the life of the insulation is that of the small part immediately between the conductors. So far as dielectric heat-

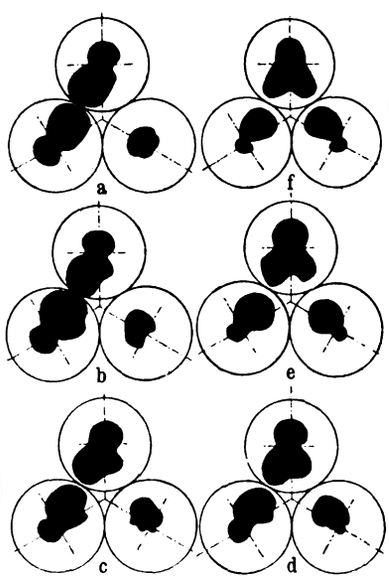

FIG. 7.—POLAR DIAGRAMS OF STRESS.

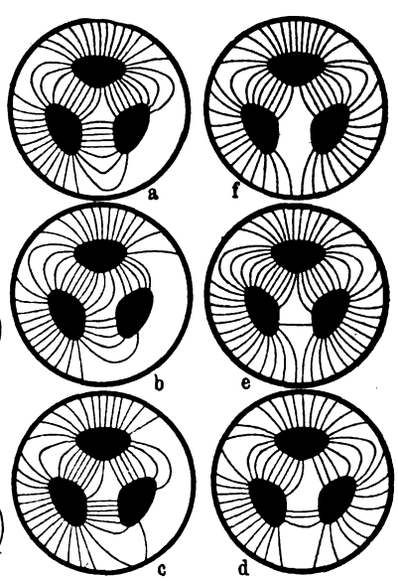

FIG. 8.—DIAGRAMS OF STRESS WITH "CLOVER-LEAF" SECTIONS.

Digitized by Google

ing is concerned, the load factor of a cable is usually high, and the effects of inequality of its dielectric heating may, for all practical purposes, be entirely masked by the copper heat. All that can be done in our present meagre knowledge of dielectric changes is to indicate the magnitude of the stress from point to point in the insulation, to provide a working basis for future theory.

—

A PAPER on the "Work of the International Electrotechnical Commission," by O. Higman, was not yet available up to the time of our going to press.

The following are abstracts of two Papers on standard cells read before Sections A and B respectively:—

On Clark and Weston Standard Cells

By DR. H. L. BRONSON (Assistant Professor of Physics), and A. N. SHAW (Demonstrator of Physics, McGill University, Montreal).

The Reproducibility of the Cells when prepared according to the Specifications of Wolff and Waters.—The mean of fifteen Clark cells made in this way differed, a few weeks after their construction, from the mean of the reference cells of the Bureau of Standards, Washington, by less than 14 microvolts. The average deviation of our cells from their own mean was not more than 13, while the maximum deviation was only 31 microvolts. In the case of the Weston cells the figures were similar, but showed somewhat better agreement in every case; the difference between the mean of thirteen cells and the mean of the reference cells at the Bureau of Standards being in this case 4 microvolts, the average deviation of the cells from their own mean being 8, and the maximum deviation being 22. Some of the Clark and Weston cells were made in Washington by one of the writers and subsequently transported to Montreal. A means of direct comparison with the values of the cells at the Bureau of Standards was thus obtained. This comparison has recently been checked by a second interchange of cells. We have also had in our possession six Weston cells made at the National Physical Laboratory in London. One of these was damaged in transit; the mean of the other five differed from the mean of our other cells by only 5 microvolts.

The effect of Introducing Slight Simplifications into the Preparation of Materials.—About twenty-five cells were constructed in order to examine the effects of slight simplifications in their preparation. It was found that the ingredient of main importance is the mercurous sulphate, which must always be prepared with great care. When unpurified mercurous sulphate was used in a cell, the average electromotive force was found to be from 300 to 500 microvolts higher than that of the normal cell. The purification of the zinc and cadmium salts is not so important, and as the processes are somewhat tedious, especially in the case of cadmium sulphate, it is interesting to see what accuracy may be obtained with various samples of chemically pure commercial sulphates. It was found that no Clark cell made with this modification differed by more than 50 microvolts from the mean of our normal cells, while no Weston cell differed by more than 100 microvolts. Such cells are therefore sufficiently accurate for all practical work. The presence of basic oxide, oil, or small quantities of organic impurities was found to exert only a very small influence on the electromotive force.

The Relative Value of Cells set up according to the Board of Trade Specifications and those set up according to the Specifications of Wolff and Waters.—Ten Clark cells of the old "test-tube crystal" type were prepared from a number of different samples of chemically pure commercial materials, for the purpose of ascertaining how much they differed in voltage from those set up according to the modern specifications. The average electromotive force of these cells during the first seventy-five days, neglecting the first day, was 0·31 millivolts higher than the mean of our normal cells. The average deviation of these cells from their own mean was considerable, about 0·06 millivolts, which suggests that there might be a possible variation of three or four in the last figure of the mean for different batches of ten cells set up with different materials. It is therefore in good agreement with the value (0·00030 volts) given by Wolf and Waters.

The Ratio of the Electromotive Force of the Weston Cell to that of the Clark.—The determination of this ratio, which had also been obtained at the Bureau of Standards, was made with the object of furnishing a further check on the reliability of the comparison between our cells and those of the Bureau, and to give added assurance that no errors had been introduced by transportation. Five Clark cells were connected in series and placed in opposition to seven Westons similarly connected. The difference between the two sets was then measured on a Kelvin-Varley slide by the usual potentiometer method. The ratio obtained was 0·716953, which differs from the ratio 0·716958, determined by Wolff and Waters, by only seven parts in a million. This difference, small as it is, is entirely accounted for by the small differences, as ascertained by direct comparison between our cells and those made at the Bureau of Standards.

Mercurous Sulphate for Standard Cells

By DR. CHARLES J. J. FOX.

It is now well established that the chief cause of inconstancy in cadmium cells is usually due to irregularities in the mercurous sulphate. F. E. Smith has investigated this matter pretty exhaustively,* and has suggested four different methods for preparing reliable Hg_2SO_4.† The present author wishes to suggest a fifth method which he has used, and which for simplicity and reliability seems to be superior to any of them. There is no difficulty in purchasing Hg_2SO_4, which is quite free from foreign metals. But these commercially pure preparations taken as they are, are unsuitable for use in standard cells because they have usually been precipitated from the nitrate solution in the cold, and are therefore not well crystallised; free nitrate and basic sulphate are also present. But if commercially pure Hg_2SO_4 be heated together with a little pure Hg and dilute H_2SO_4 for a day or so at 120° to 150° in either a sealed tube (1 to 2 millimetre walled tubing) or bottle with wire-bound stopper, and occasionally agitated, a white crystalline preparation will be obtained even from a specimen of Hg_2SO_4 which is initially discoloured almost black. On opening the tube or bottle it will usually be noticed that the pressure has risen a little, and that there is a trace of NO_2 formed; a little care should therefore be employed if there is more than a trace of nitrate in the original Hg_2SO_4. But the Hg_2SO_4 obtained in this way is itself free from nitrate and especially if the Hg_2SO_4 be filtered off and renewed during the heating process; it is also, of course, quite free from basic salt. It is filtered off, ground up in a mortar with one or two successive quantities of diluted H_2SO_4, and then with several quantities of saturated cadmium sulphate solution; it is filtered off in a Büchner funnel after each washing. In this way it is possible with very little trouble to prepare quite large quantities of very reliable, well crystallised, white Hg_2SO_4 in every suitable way for standard cells. By heating with HCl and Hg, it is also a very convenient method of preparing crystalline calomel; but in this case the heating takes about twice as long owing to the small solubility of calomel compared with Hg_2SO_4.

Telephone Expansion in America.—The New York *Financial Chronicle* has published a census bulletin in order to illustrate the enormous growth of the telephone service in the United States of recent years. Out of 15,072,000 miles of single wire in the combined telegraph and telephone services, no less than 13,000,000 miles are controlled by the telephone, whilst of 142,700 employees, 119,000 belong to the telephone service. The gross earnings of the telephones amount to $140,802,000 for the census year, against $51,584,000 from the telegraphs.

Iron and Steel Institute Autumn Meeting.—The autumn meeting of the Iron and Steel Institute will be held in London from September 27th to October 1st inclusive. The headquarters of the Secretary during the meeting will be at St. Ermins Hotel, Westminster, S.W., and the meetings will be held at the Institution of Civil Engineers, 25 Great George Street, Westminster. Among the Papers down for reading are the following: "On the Determination of the Power Consumption of Reversing Rolling Mills," by C. A. Ablett; "On the Refining of Steel by Electricity," by E. J. Ljungberg; "On the Maintenance and Renewal of Permanent Way," by R. Price-Williams. Among the works to be visited are the following: Messrs. Siemens Bros. & Co., Ltd. (Woolwich); L.C.C. Generating Station, Woolwich; and the National Physical Laboratory. On Friday, October 1st, a special visit is to be made to Portsmouth Dockyard and H.M. Naval Establishments. A dinner will be given by the Reception Committee at the Trocadero Restaurant, Shaftesbury Avenue, on Wednesday, September 29th.

Institution of Mining Electrical Engineers.—A Council meeting of the Institution of Mining Electrical Engineers was held at the Royal Victoria Hotel, Sheffield, on Saturday, the 21st inst. The branch Presidents and representatives present included Messrs. R. Hood Haggie (South of England), Sidney F. Walker (South Wales), H. W. Clothier, A. M. C. Field, H. J. Fisher (North of England), Arthur Hall (Warwickshire and Staffordshire), J. A. Boshes (North Wales), J. Kirkby and F. Cusworth (Derbyshire and Notts), P. D. Coates and J. H. C. Brooking (Lancs.), R. J. Frost (Rotherham), and others, the President of the Institution (Mr. William Maurice) being in the chair. A report was presented by the Hon. Secretary (Mr. J. G. Williams, 3 Moresby Parks, Whitehaven), showing that the membership had now reached 300, with a prospective immediate increase to 400 by the addition of candidates who had not yet been formally elected. The Draft Memorandum and Articles of Association were submitted and provisionally approved. It was resolved to create a Diploma Class of Membership, to which candidates could only obtain admission by examination, after having had an approved term of practical experience in charge of electrical plant in mines. It was further arranged that entrance fees should be payable by members of all classes who join after the incorporation of the Institution. The meeting closed at 8.30 p.m., having sat for five and a half hours.

MAXIMUM DEMAND INDICATING ATTACHMENT FOR CLOCK METERS

THE Aron Electricity Meter Co., Ltd. (80A Salusbury Road, Kilburn, London, N.W.), have introduced a modified pattern of their well-known clock-type meter, comprising a meter mechanism of the standard pattern suitable for any direct-current or alternating-current system, and an attachment for indicating the maximum demand.

Maximum demand indicators may be divided into two classes —"sluggish" and "non-sluggish"—according to whether the instrument is required to indicate the maximum average demand over predetermined periods, or the maximum demand at any instant. The "Aron" indicator belongs to the former class which necessitates the introduction of some periodical releasing device; this device is already provided for in the "Aron" meter by the change-over gear, which includes a wheel driven at a constant speed and independent of the meter itself. The principle of the indicator is based on the fact that the revolutions of the counting train wheels in a given time are exactly proportional to the units or ampere-hours registered in that time, and the pointer of the indicator travels over a certain angle during the same time. The indicator is geared to the fifth wheel of the train. Were the indicator permanently attached to the counting train, it would continuously turn round as the meter registers. The change-over gear, however, is caused to throw the wheel work of the indicator out of gear with the counting train of the meter, which former (but not the pointer) will return to its zero position, and will be brought into action again immediately afterwards.

MECHANISM OF MAXIMUM DEMAND INDICATING DEVICE FOR CLOCK METERS.

The mechanism effecting this movement is illustrated in the accompanying figure. A pin, *a*, is fixed on the arbor carrying the pointer which indicates the maximum demand. This pin is moved forward by means of a small arm *b*, attached to the indicator wheel, *g*, which latter is controlled by a hair spring. At certain pre-arranged regular intervals—generally 20 minutes, but more or less if desired—the change over gear of the meter, connected to wheel *c*, lifts the double lever *d*, thereby disengaging the wheel *e*, which is connected with the counting mechanism of the meter, from the indicator wheel. The indicator wheel *g*, being left free, is carried back by the hair spring which controls it to its original position against the stop *f*, leaving the pointer behind on the dial. The dial is calibrated in kilowatts or amperes, as the case may be, and thus the deflection of the pointer indicates the average demand during the period under notice. After a few oscillations of the pendulums of the meter proper, the double lever *d* drops, and the wheel *e* again slides into gear with the indicator wheel.

If the mean energy in the next period is less than it was previously, the wheel will not move far enough to carry the pointer any further over the scale than it was before, so that the indication of the first period will remain. If, however, in the third, or in any subsequent period, the mean energy is greater than in the first period, the wheel will catch up the pointer and carry it further over the scale, but the wheel will spring back to zero every time it is released.

The following example will show clearly the meaning of the indications :—Let the meter be of 60 kw. maximum capacity, and the period during which the maximum demand is to be indicated 20 minutes. The scale of the indicator is divided into 60 parts, each representing 1 kw., and the pointer is so arranged that it moves entirely round the scale and indicates 60 kw. if in 20 minutes 20 units have passed through the meter, this being the highest amount for which the meter is constructed. Under actual working conditions the meter may register as follows :—6 units in 8 minutes, then 4 units in 4 minutes, and then 4 units in 8 minutes, making a total of 14 units in 20 minutes. The pointer of the indicator will, during the first 8 minutes have moved to 18 scale divisions, this being at the rate of 45 K.W. or $\frac{4}{6}\frac{5}{0}$ of the maximum, and for 8 minutes only, instead of 20. Therefore $\frac{8}{2}\frac{}{0} \times \frac{4}{6}\frac{5}{0} \times 60 = 18$ K.W. During the next 4 minutes the rate is 60 K.W., the maximum, and the period only $\frac{4}{2}\frac{}{0}$. Therefore the pointer will move $\frac{4}{2}\frac{}{0} \times \frac{6}{6}\frac{0}{0} \times 60 = 12$ divisions on, showing now 30 K.W. For the last 8 minutes the rate corresponds to 30 K.W. being $\frac{3}{6}\frac{0}{0}$ of the maximum, and for a period of $\frac{8}{2}\frac{}{0}$. Therefore the pointer will move $\frac{8}{2}\frac{}{0} \times \frac{3}{6}\frac{0}{0} \times 60 = 12$ divisions further, showing at the end of the 20 minutes 42 K.W. this being the average of the three loads, taking into consideration the length of time. If the average demand in any consequent 20 minutes is greater, the pointer will be carried on farther. At the end of the month or quarter, the pointer is moved back by hand to zero.

The appearance of an Aron meter fitted with this attachment is similar to that of the ordinary Aron meter with the addition of a dial indicating maximum amperes. It is made with springing figures, or the ordinary rotating arrow dials, as preferred. A modification has been made in a number of these meters which are being supplied to the North Metropolitan Electric Power Supply Company. This consists in cutting out a small circular opening in the dial face opposite the moving wheel *e*, so that the exact interval during which this is in gear with the indicator wheel can be tested. A further detail modification consists in providing a small arrow which indicates approximately on the front of the dial the progress of the 20 minutes interval, so that the tester need only watch the wheel *e* for a few seconds, when the arrow indicates that the interval is just to begin or nearly up, as the case may be.

New Siemens-Schuckert Wire-drawing Works.—According to the *Elektrotechnischer Anzeiger*, the Oesterreichische Siemens-Schuckert-Werke, of Vienna, are taking up the manufacture of copper wire, and a large works, fully equipped with copper rolling and drawing machines, is now being erected close to the cable works of the company at Leopoldau. The new works is to be completed by the end of this year, and will deal with the material from the ingot stage.

Cable Traction.—With reference to our remarks upon cable traction in our last issue (page 764), a correspondent informs us that the cable system in Birmingham is still in operation, and likely to be until the end of 1911. Our correspondent claims that on this route, which is about three miles long, there is probably the finest service of any tramway route in the United Kingdom, with a 1¼-minute service at busy hours.

"Engineering Day" at the Imperial International Exhibition.—In connection with the proposal to hold an "Engineering Day" at the Imperial International Exhibition, Shepherd's Bush, on Saturday next, September 4th (ELECTRICAL ENGINEERING, August 26th, page 765), the P. & O. Batti Wallah's Society specially request as many of their members as possible to attend, in order to form a separate party.

Institution of Mining Engineers.—The annual general meeting will be held at the North of England Institute of Mining and Mechanical Engineers, Newcastle-on-Tyne, on Wednesday, September 15th, at 11 a.m. The Institution dinner will be held in the evening. Arrangements have been made for excursions and visits to works, collieries, &c., on September 16th and 17th. Among the latter is the Carville power station of the Newcastle-upon-Tyne Electric Supply Co., Ltd. Among the Papers for discussion is "Electricity in Coal Mines," by Mr. R. Nelson, H.M. Electricial Inspector of Mines. This Paper was read at the recent London meeting (ELECTRICAL ENGINEERING, June 10th, page 527).

Japan-British Exhibition, London, 1910.—Arrangements are being made to hold a Japan-British Exhibition at the White City, Shepherd's Bush, in 1910, commencing on May 3rd, and remaining open until October. The Japanese Government have already voted 1,800,000 yen, and the Government of Formosa and the Local Prefectures have also voted large sums for the Exhibition. The Japanese Government have secured a large portion of the existing Exhibition buildings and grounds, and the Japanese section will be divided into 18 groups, including electricity, civil engineering and transportation, mines and metallurgy, and mechanical engineering. British firms desiring to take space are requested to apply to the Secretary of the Exhibition, at the offices, Shepherd's Bush.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 26th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

16,620/08. **Stranded Conductors.** C. A. PARSONS, J. H. GREAVES, and A. R. HEMSTED. Flattened, stranded, coreless conductors, particularly suited for high-speed smooth-core armatures, and also for slotted A.C. armatures, are manufactured by twisting wires round a fixed dummy core by means of a revolving drum carrying the spools, and then passing the wire tube so formed between two rollers, which flatten it into the required flat conductor. The wire tube may be formed inside a tubular die instead of round a dummy core. Additional layers of wire may be placed over the flattened cable. The flattening process does not damage the insulation of the individual strands, which may be of cotton or enamel. Ten claims, eighteen figures.

16,704/08. **Armatures for High-speed D.C. Machines.** C. A. PARSONS and A. H. LAW. The conductors are only partly embedded in the iron, so that the self-induction of the windings is not appreciably increased over that of a smooth-core armature, while the use of binding wires is avoided. To increase the magnetic path round the conductors, they are made flat and thin, one edge being expanded or shaped so that they can be locked in the slots by means of a wedge or by other suitable means. If cable, stranded as described above, is used, it can be previously shaped so as to be held easily in dove-tail slots, by passing it between specially formed rollers. Eight claims, twelve figures.

20,64608. **Knife Switch.** VERITY'S, LTD., and W. G. PIPKIN. This is a switch in which both quick make and break are obtained, by means of a spring arrangement adapted to operate each side of the pivot of the blades. The springs are inoperative until the switch arm has been moved over a certain arc in each case, after which it comes into operation and causes a quick make or break as the case may be. Five claims, three figures.

22,768/08. **Interlocked Iron-clad Switch Case.** F. S. HORROCKS and T. C. LEIT. A small lug is cast on the opening side of the case, and a similar lug is cast on the cover. The holes in these lugs coincide when the cover is closed. When the switch is closed, a long bolt or pin connected by a link with the actuating mechanism, slides through both holes and locks the cover. On opening the switch, the bolt is withdrawn so that it lies only in the casing lug. The switch-blades break contact before the bolt leaves the cover lug, so that it is impossible to open the cover at all while the switch is closed. One claim, two figures.

5,209/09. **Constant Current Motor-generator Set.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). The armatures of the two machines are connected in series. Each has one set of short-circuited brushes on a line at 90 electrical degrees to the main field, and a set of brushes displaced 90 electrical degrees to the first set, through which the armatures are connected in series. The load to which constant current at varying potential is to be supplied is connected across one armature. Three claims, one figure.

Application for Amendment

25,631/96. **Electrolytic Process.** T. PARKER. The British Coalite Co., Ltd., seek leave to amend this specification, which relates to the electrolytic production of the chlorates of sodium and potassium. The amendment consists in striking out the first claim, which is said to be of doubtful novelty. This is for an electrolytic cell, the iron tank of which, together with the plates, forms the cathode, the anode consisting of suspended carbon plates or rods. The remaining claims refer to a cell such as the above, without a diaphragm, and with a layer of pumice or cork floating on the surface of the solution.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: HANN [Conduit jointing] 16,863/08; BRITISH THOMSON-HOUSTON Co., and WEDMORE [Protective devices] 17,890/08 and [Protective devices for A.-C. systems] 20,498/08; GOULD [Supports for electric wires] 7,610/09.

Dynamos, Motors, and Transformers: BRESLAUER [Compounding of A.-C. generators] 14,897/08; BRITISH THOMSON-HOUSTON Co., and CARTER [Control of machines] 16,997/08; SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke-Ges.*) [Regulation of machines] 1,509/09; MOSER [A.-C. machines] 6,103/09.

Electric Ignition: POSTANS [Ignition devices] 17,159/08.

Electrometallurgy and Electrochemistry: SCHAULI [Primary cells] 14,609/08; HUNTE [Dry cells] 14,615/08; CLARK [Coating iron with copper] 16,820/08; SCHAULI [Depolarisers for primary cells] 24,355-6/08.

Switchgear, Fuses, and Fittings: GARSIDE [Motor starters] 13,965/08; BRYANT and PEARSON [Automatic distributing switchgear] 25,134/08; DEY [Motor-starter and regulator] 759/09; SIEMENS BROS. DYNAMO WORKS, and PAYNE [Retarding mechanism for motor-starters, switches, &c.] 4,317/09; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Automatic regulators] 4,882/09.

Telephony and Telegraphy: MAYRAND [Keyboard transmitter] 16,791/08.

Traction: SIEMENS BROS. & Co. (*Siemens & Halske A.-G.*) [Single-line signalling] 14,784/08; SHEARS [Magnetic brakes] 17,211/08; BRYAN [Trolley poles] 20,575/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Signalling] 21,766/08; LEGAULT [Operation of points and switches] 8,846/09; W. R. SYKES INTERLOCKING SIGNAL Co. [Stopping trains] 9,984/09.

Miscellaneous: LOHAY [Electrical control of mechanism from a distance] 14,396/08 and 14,420/08; STALDER, SCHOLL-SCHOLL, and DUBACH [Process for soldering aluminium] 23,779/08; REICHEL [Fire alarm] 197/09; VON WYSOCKI [Thermo-piles] 11,230/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: SIEMENS SCHUCKERTWERKE-GES. [Flame arc lamps] 18,328/09.

Electric Ignition: UNTERBERG and HELMLE [Contact-breaker] 4,030/09; ROGERS [Distributing mechanism] 16,943/09.

Instruments: SIEMENS SCHUCKERTWERKE-GES. [Apparatus for indicating differences of pressure] 17,620/09.

Telephony and Telegraphy: STRAGIOTTI [Telephone transmitter] 17,473/09, and [Micro-receivers or translators] 17,542/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: E. WEINTRAUB (*General Electric Co., U.S.A.*) [Mercury-vapour lamps and rectifiers] 24,502/03; E. A. CAROLAN (*General Electric Co., U.S.A.*) [Mercury-vapour lamp for producing ultra-violet rays] 10,881/04; H. DIAMANT and A. CHIESA [Feeding mechanism for inclined carbon lamp] 9,783/05.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: S. G. BROWN [Submarine telegraph cables] 10,667/03; A. BERLIN [Cables with large self-induction] 9,865/05.

Dynamos, Motors, and Transformers: C. A. VANDERVELL and W. H. PROCTOR [Dynamo with rotating field and armature] 10,748/04; A. F. BERRY [Transformer windings] 10,800/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Electric driving gear for automobiles] 10,880/04; A. P. WOOD [Load equalising flywheel set] 9,739/05; BRUCE, PEEBLES & Co. and J. LA COUR [Compounding synchronous machines] 9,839/05, and [Control of single-phase motors] 9,839/05; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Multiple-speed polyphase motors] 10,017/05.

Electric Ignition: C. T. SANGSTER [Distributer] 9,815/05; ELECTRIC IGNITION Co. and F. H. HALL [Switch] 9,991/05; LA FORCE [Sparking Plug] 26,970/05.

Electrometallurgy and Electrochemistry: E. ANDREOLI [Ozonising apparatus] 9,741/99; H. BLACKMORE and E. BYRNES [Electrolytic production of sodium] 10,794/04; G. E. GAIFFE [Production of ozone] 22,103/05.

Instruments and Meters: C. W. ATKINSON [Electrolytic meter] 11,093/04.

Switchgear, Fuses, and Fittings: W. FELLENBERG [Enclosed fuse] 10,656/04; L. ANDREWS [Reverse current relay for circuit-breakers] 10,722/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Reverse energy relay for A.C. circuit-breakers] 10,878/04; A. P. and G. C. LUNDBERG [Three-terminal ceiling rose] 11,056/04; BRITISH THOMSON-HOUSTON Co. (*Allgemeine Elektricitäts Ges.*) [Oil-break switch] 11,073/04; R. W. BELL [Lamp suspender] 9,713/05.

Telephony and Telegraphy: S. G. BROWN [Telegraph relay] 9,801/01, and [Submarine cables] 10,667/03; G. HUGHES (*M. A. Murray*) [Wireless fog-signalling apparatus] 10,914/03; G. MAGINI [Filings coherer] 9,219/05; F. W. HOWORTH (*Deutsche Telephonwerke, R. Stock & Co.*) [Telephone exchanges] 9,884/05.

Traction: J. OHMER [Fare registering device] 11,706/97; BRITISH THOMSON-HOUSTON Co. (*E. F. Case, U.S.A.*) [Controller with contacts for electric braking] 10,134/99; BRITISH THOMSON-HOUSTON Co. (*W. B. Potter, U.S.A.*) [Retarded handle for controllers] 10,135/99; W. R. SYKES [Electrically worked points and signals] 10,502-3/03; T. BLANEY [Trolley head] 10,812/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Signalling system] 11,077/04.

Miscellaneous: R. & K. OTTO [Light treatment apparatus] 10,889/98; C. MILLS (*G. Schoeffel*) [Electrically operated steam valve] 9,960/99; N. JACOBSEN [Alarm signal system] 10,376/04; O. FELDMANN (*W. Faber*) [Electric signs] 9,799/05.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The electrical mining regulations in New South Wales are in some respects far more drastic than those now in force in this country. Reports are to be kept of such accidents as overheating and the appearance of sparks outside enclosing casings of apparatus, and any cases of apparatus becoming live are to be recorded. Trailing cables are to be tested once a month after six hours' immersion in water, the results are to be logged, and no trailing cable must be taken into use if the insulation is less than one megohm. The machine-man in charge of a coal-cutter must be competent to examine the roof and sides, and to detect the presence of gas. (Page 791.)

The grant of a patent applied for by Messrs. Willoughby S. Smith and W. P. Granville for a flexible loading coil which can be inserted into a telegraph or telephone cable under the sheath in the course of manufacture, is being opposed by Messrs. Siemens Bros. & Co., who allege that the invention has been anticipated by a prior patent of their own. In both cases the coils are wound longitudinally, practically parallel to the length of the cable, and there is an iron core between the inner and outer turns of the coils. In the case of the Smith and Granville patent this iron core is made up of a layer of iron wires, and in the Siemens patent it is described as an iron cylinder and flexible distance pieces are inserted between adjacent coils. (Page 791.)

Three 50-ton continuous-current locomotives have been supplied for the British Columbia Electric Railway. These are of the articulated-truck four-axle type, with one motor on each axle. The motors are provided with forced ventilation. (Page 793.)

A device for use with C.-B. telephone instruments to perform the function of the handle-key of the combined hand set from the user's point of view is described on page 794.

A new system of electric water heating for domestic purposes, in which the current is employed practically at 100 per cent. load factor, is described on page 795.

The annual conference of the Municipal Tramways Association will be held in London from September 22nd to 24th inclusive, under the Presidency of Mr. A. L. C. Fell, Chief Officer of the London County

Digitized by Google

Council Tramways. We give the full programme. (Page 795.)

A NEW finishing tool in the shape of an adjustable reamer has been introduced by Messrs. Vickers, Sons & Maxim. (Page 796.)

THE Wolfram (Tungsten) Metal Filament Lamps, Ltd., have been given permission by the Comptroller General of Patents to amend the specification of the fundamental British patent for the manufacture of pure tungsten filaments, in three important respects. All references to the metal molybdenum have been deleted; a description of a chemical process for substituting tungsten for carbon has been taken out; and a disclaiming clause taking note of three prior patents relating to metal filaments has been added. The patent now covers a process for manufacturing pure tungsten filaments by mixing a powdered tungsten compound with an organic binding agent, squirting this mass into filaments, carbonising, and then removing the carbon by raising them to a high temperature in an atmosphere of steam and hydrogen. (Page 797.)

THE accounts of the Pacific Cable Board for the year to March 31st, 1909, show a deficiency of £62,362, after allowing for sinking fund charges. The actual receipts exceeded the working expenditure by £16,657. (Page 797.)

THE India-Rubber, Gutta-Percha, & Telegraph Works Co., Ltd., of Silvertown, who have complained of the high rates at West Ham, are looking out for a suitable site to which to remove a portion of their works, but the report that Peterborough has already been selected is, we understand, at any rate, premature. (Page 798.)

NEGOTIATIONS are proceeding between the Postmaster-General and Marconi's Wireless Telegraph Co. for the acquisition by the former of the company's land stations. In future, under the agreement, all land stations will be erected by the Post Office. The company, however, will retain the transatlantic stations at Poldhu and Clifden, and will continue to work the ship stations and retain the receipts therefrom. An official statement will be issued when the negotiations are finally completed. (Page 798.)

THE recent collision between two trains at Moorgate Street, on the Metropolitan Railway, has been found to have been caused by the failure of an automatic signal. A valve, which should have allowed oil to escape from the cylinder and thus permit a piston to descend and raise the signal arm, was stopped up by sediment in the oil. These valves are to be redesigned. (Page 798.)

ON Saturday last a number of engineers attended a meeting organised by the Engineering Committees of the Imperial International Exhibition. Mr. A. Steiger drew attention to the possibilities of developing the water power of the United Kingdom in a Paper on "Water Power and Turbines." In a lecture by Mr. P. R. Allen, the development and application of the large gas-engine was described. A Paper by Mr. John McLaren dealt with the advantages of substituting a gas-engine generating plant and electrical distribution of power on board ship for steam-driven auxiliaries. During the afternoon, the machinery for operating the various amusement devices was inspected. The new "Submarine Railway" requires four 50-h.p. motors to haul its boats round the partly submerged circular track. (Page 799.)

A LETTER from Mr. H. J. Fisher, of the Lambton Collieries, mentions the unfortunate moral effect of the West Stanley disaster, in spite of the fact that no explosion has hitherto been caused even by old installations that have been allowed to lapse into bad condition. He recommends that all apparatus should pass a Government inspection, and should be placed on an approved list before use, and suggests that an electrical inspector should be appointed for every district.—Mr. W. Winsborough, of the Douglas Bank Colliery, describes the method of cable-laying, bonding, and earthing employed in his pit, which, under proper inspection and testing, has given no trouble. (Page 801.)

THE annual report of the Aberdeen Corporation electrical engineer states that there are 25,000 metal filament lamps on his mains, and expresses the opinion that the effect of these lamps upon the consumption will continue to be felt for the next two years.—In spite of the advice of their electrical engineer in favour of a slower speed turbo set, the Sydney Corporation are in favour of installing a 4,000-kw.-turbo generator running at 1,200 r.p.m.—The tramway centre-poles in Belfast are to be removed.—The Kingstown (Dublin) Council have confirmed their decision to oppose the application of the Dublin United Tramways Co. for an increase of speed on their "express" cars.—Recent concessions to workmen upon the Salford tramways have proved financially unsuccessful. (Page 802.)

GENERATING plant to the estimated value of £34,000 is required by the Johannesburg Corporation.—Hackney Borough Council propose electrical extensions at an estimated cost of £3,650.—Single-phase A.C. meters are required at Dublin.—Particulars are given of several large electrical projects on the Continent. (Page 803.)

THE accounts of the British Thomson-Houston Co., Ltd., for the year to March 31st show a loss of £825, after paying interest on debentures and loans.—A profit of £12,083 is shown by the accounts of the United Electric Car Co., Ltd., for the year to June 30th. A dividend of 2½ per cent. is recommended. (Page 804.)

MESSRS. DRAKE & GORHAM are placing on the market a new design of enclosed arc lamp. (Page 805.)

AMONG the specifications published by the Patent Office on Thursday last was one by T. G. Hann for joints for wiring conduit, in which the conduit tubing is flared out at the ends, the flange being gripped by the jointing piece, which is in two halves. A specification by the British Thomson-Houston Co., and F. W. Carter describes a method of controlling compound-wound traction motors for regenerative braking. The series field is short-circuited under normal conditions, but assists the shunt field on overloads, and opposes it when the motor begins to generate. C. Shears has patented a construction for magnetic track brakes in which the magnet coils are well protected from injury and moisture. Siemens Bros. Dynamo Works have a specification describing a device for protecting A.-C. generators with automatic voltage control, consisting in relays which insert a resistance in the exciter field circuit on the occurrence of a short-circuit on a feeder. Application for the amendment of a specification relating to the manufacture of tungsten filaments has been made by the "Z" Electric Lamp Syndicate. In spite of opposition, a patent has been granted to Marconi's Wireless Telegraph Co., and H. J. Round for a wave-length measurer. (Page 806.)

"The Electron."—The August number of this magazine, the official organ of Siemens' Stafford Institute, has for its frontispiece a view of the erecting shop of the Stafford Works. An article on the driving arrangements for full-gauge electric locomotives, and the first of a series of articles on the various works of the Siemens' companies, beginning with a description of those at Nürnberg and Charlottenberg, and including a few notes on the conditions of living among the employees, are followed by the conclusion of Dr. Kloss's Paper on the starting torque of three-phase squirrel-cage motors. Mr. J. Okell contributes an illustrated article on the application of the internal-combustion engine to road vehicles, and an article on milling machines, the first of a series dealing with machine tools of all kinds, is also included. Some particulars of the classes given at Stafford Technical Schools, and which will render unnecessary the courses arranged for by the Educational Section of the Institute, and the usual reports of the social sections of the Institute conclude this number.

ELECTRICAL MINING REGULATIONS IN NEW SOUTH WALES

A SHORT time ago, Mr. A. A. Atkinson, Chief Inspector of Coal Mines in New South Wales, published a report in which he gave the special regulations adopted for the majority of the large collieries in that country with electrical installations. They follow, in general, the same lines as the Special Mining Rules in this country, but there are some important points of difference, which we indicate below.

Two excellent regulations have been made, relating to the reporting of accidents:—

Every personal accident occurring in connection with the operation of the electrical equipment (including electric shocks and burns) shall be promptly reported by the person injured or by some other person on his behalf at the office of the mine, and shall be there recorded.

In the event of any instance occurring of breakdown of, or damage or injury to, any portion of the electrical equipment in the mine, or of over-heating, or of the appearance of sparks or arcs outside the enclosing casings, or in the event of any portion of the equipment (not being a proper part of the electrical circuit) becoming alive, every such occurrence shall be promptly reported in a book, kept at the mine for the purpose, and signed by the person making such report.

A table is given for the sizes of conductors (other than overhead wires on the surface and wires inside motors). In the case of lead-covered cables, and for all cables below ground, where the temperature does not exceed 100° F., the sizes are the same as those specified in the present edition of the Institution of Electrical Engineers' Wiring Rules, and in the case of cables with waterproof dielectric under other conditions, the currents and sizes correspond to the table in the previous edition of the Institution Rules for situations in which the external temperature is high.

In estimating the sizes of conductors in cables supplying coal-cutters not in a long-wall working, a deduction of 20 per cent. from the normal working current is permissible. There are special rules for trailing cables which contain far more stringent provisions than are enforced in this country at present:—

Trailing cables for portable machines shall be specially flexible, heavily insulated, and protected with extra stout braiding, hose pipes, or other equally effective covering. Bare metal armouring shall not be used upon any trailing cable carrying current at a pressure exceeding the limits of low pressure.

Each trailing cable shall have a distinguishing number, which shall be clearly indicated on a suitable label securely attached to the cable. The insulation resistance of each conductor of every trailing cable shall be measured and recorded at least once per month; the resistance being taken between the conductor and the surrounding water after the whole cable, with the exception of the ends, has been immersed for at least six hours. For this test the manager must supply an instrument suitable for measuring resistance up to at least 5 megohms. The trailing cable must not be put into service unless the insulation resistance of each conductor measures at least 1 megohm after immersion.

Careful scrutiny on the part of machine-men in charge of coal-cutting machinery is enjoined:—

The machineman in charge for the time being of a coal-cutting machine must be a competent person, capable of examining the roof and sides and detecting the presence of inflammable gas.

If any electric sparking or arc be produced outside a coal-cutting or other portable motor, or about the cables or rails, the machine shall be stopped, and shall not be worked again until the defect is repaired; and the occurrence shall be at once reported to an official of the mine.

From these brief extracts it will be seen that the regulations are in some respects far more drastic than those to which mining engineers are accustomed here.

LOADING COILS FOR TELEGRAPH AND TELEPHONE CABLES

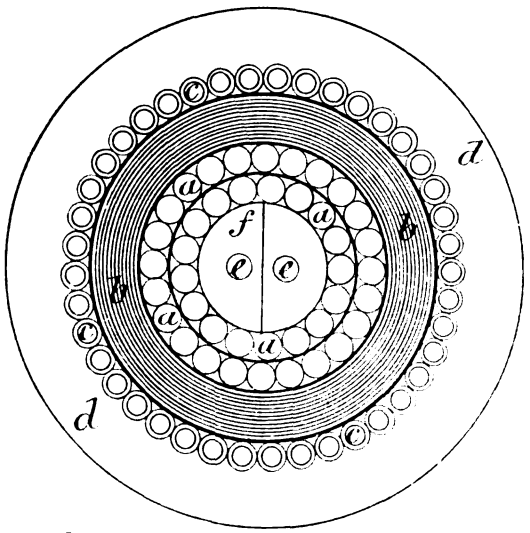
Opposition to the Grant of a Patent

THE grant of a patent to Messrs. Willoughby S. Smith and W. P. Granville for a method of manufacturing flexible inductance coils for insertion into telegraph and telephone cables at intervals along their length in the course of manufacture, is being opposed by Messrs. Siemens Bros. & Co. Provisional protection was applied for on Dec. 17th, 1908, and on Feb. 22nd, 1909, and the complete specification was accepted on June 17th, and published on July 8th last. Messrs. Siemens Bros. & Co. allege that the invention has been anticipated by their patent No. 25,306 of Nov. 9th, 1906 (granted to them conjointly with Mr. William Dieselhorst, and partly communicated from abroad by the Siemens & Halske Akt.-Ges.), and, as an alternative reason for the refusal of the patent, they assert that the nature of the invention and the manner in which it is to be carried out are not sufficiently described in the complete specification.

Messrs. Willoughby Smith and Granville's patent is numbered 27,470 of 1908, and the method of manufacture is described as follows:—

We first form what we may call a cable. We strand or twist together a number of separately insulated conducting wires hereinafter referred to as "inner wires" and around the exterior of any desired length of this assemblage of inner wires we wind closely adjoining coils of soft iron wire to form around it an iron covering of any desired thickness, and on the exterior of this iron wire we strand "outer wires," *i.e.*, separately insulated conducting wires, one less in number than the inner wires. These outer wires are preferably the inner wires or the continuations thereof (all but one) bent back as it were upon themselves at one end of the iron covering. We now connect the free ends of the inner wires to the free ends of the outer wires at each end of the cable in such a way as to make a continuous coil or winding around the iron wire, but one inner wire is left unconnected at each end of the cable to form the two ends of the winding. The whole is then covered with a coating of insulating material and a flexible inductance coil is thus formed. Of course, if the inner wires are bent back to serve as outer wires, as mentioned above, it will only be necessary to connect up the inner and outer wires at the one end of the cable instead of at both ends.

If it is desired to make an inductance coil with two windings, then the inner and outer wires are so connected as to form around the iron two distinct and continuous windings, care being taken that the free ends of one winding are inner wires, and therefore at opposite ends of the cable, while those of the other winding are outer wires. In this case the numbers of outer will be equal to the number of inner wires. Further, should we require a coil for use in a cable containing more than one telephone circuit, we provide either amongst the inner or amongst the outer wires a pair of straight-through conductors for each telephone circuit besides the first. Moreover, we may make a long cable and cut it into several pieces, each of which will form an inductance coil. In such a case it will be necessary to remove the iron wire for a sufficient distance at each end of each piece to enable the inner and outer wires to be connected. The whole coil is now suitably coated with insulating material.



The manner of introducing the coils in the cable is next described:—

Flexible inductance coils so formed may be introduced at intervals into a telephone cable before covering with its outer metallic sheathing, the core or cores being severed where a coil is to be introduced and the ends of the telephone line connected to the free ends of the winding of the coil. If the telephone line is double, that is, if there is a go and a return line, then coils with two windings (or two single-wound coils) will be used, and the two lines will be connected to the two windings respectively. If, again, the telephone cable contains two circuits, in other words, if it is a four-conductor cable, then coils with two windings and one pair of straight-through conductors will be required; in this case the wires of one circuit, say the first, will be connected to the windings of the coil, and the wires of the second circuit to the straight-through conductors; but where the next coil is inserted the wires of the first circuit will be connected to the straight-through conductors, and those of the second circuit to the windings of the coil. The accompanying drawing is a section through a coil made as described above—*a* are the inner wires, *b* the coils of iron wire, *c* the outer wires, and *d* the outer insulating coating; *e e* are the two straight-through conductors embedded in insulating material *f*.

Digitized by Google

Five claims are attached to the specification:—

1. A flexible inductance coil formed by coiling iron wire around a number of insulated wires, laying a number of insulated wires around the iron coils, and connecting the inner and outer wires so as to form either a single winding or two distinct windings around the iron substantially as described.
2. A flexible inductance coil covered by Claim 1, in which the outer wires are formed of the inner wires bent back upon themselves substantially as described.
3. A flexible inductance coil covered by Claim 1, but formed by cutting a long length into pieces and connecting the cut inner and outer wires substantially as described.

SECTION OF MESSRS. WILLOUGHBY S. SMITH AND W. P. GRANVILLE'S FLEXIBLE LOADING COIL.

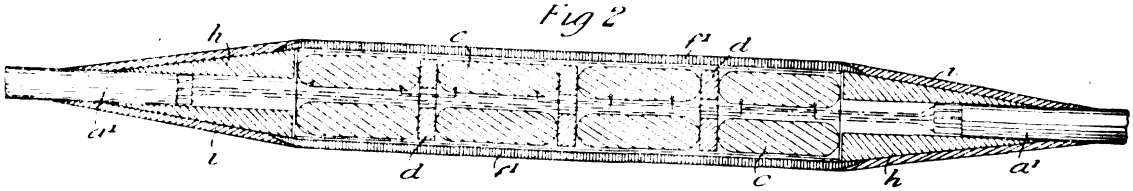
4. A flexible inductance coil covered by Claim 1, and having a pair of straight-through conductors.
5. Flexible inductance coils for telephone cables and the like substantially as described.

Messrs. Siemens Bros. & Co.'s complete specification, No. 25,306 of 1906, which they claim to be an anticipation of Messrs. Willoughby Smith and Granville's invention, reads as follows:—

The difficulty of introducing induction coils into electric cables was due chiefly to the fact that the coils detracted from the flexibility of the cable at the part where they were contained, and that the cores, which were arranged between the coils and the sheathing were liable to be damaged by the extra strain to which they were subjected in the bending of the cable. Moreover, in the case of submarine cables no satisfactory method was known for covering the part comprising the coils in gutta percha or the like materials, which are watertight coverings that will withstand the constant shifting of a cable in tidal waters. The present invention relates to a construction of electric cables, having induction coils, which minimises the aforesaid difficulties, and to a method of encasing such induction coils in gutta percha or the like. According to the invention, the induction coils are annular, preferably in the form of a long and thin hollow cylinder. These coils are successively connected with the separate cores or conductors in the usual manner. For the purpose of giving greater flexibility to the part of the cable containing these induction coils, intermediate annular pieces of elastic material are inserted between the coils.

The accompanying drawings illustrate the invention, Fig. 1 being a longitudinal section of a cable having induction coils inserted according to the invention, and encased in lead sheathing, while Fig. 2 is a like view of a similar cable encased in gutta percha. In Fig. 1 *a* is a multiple-core cable covered with lead, *b*; *c c* are the induction coils, each wound on an iron cylinder, *g*, and *d d* are the flexible distance pieces, of rubber or other similar material, between the coils. The induction coils and intermediate pieces when in place form a tube through which the cores of the cable, or the ends of the winding of the coils, are passed. The whole is then covered with a layer of tape *e*, and the lead tube *f* is put over all and soldered at the tapered ends to the lead sheathing *b*. In Fig. 2 the coils *c* and the intermediate pieces *d* are similarly put in place, and the ends of the coils are passed through their centres, one end of each towards the left and the other end towards the right; a gutta percha tube f^1, a little longer than the tube formed by the coils, and of slightly greater diameter than that of the coils, is then drawn over the latter, and the several ends of the coils are joined to the ends of the four cores respectively at each end of the tube formed by the coils, care being taken that there is sufficient slack of the coil wire to allow for stretching. For a short distance, say about 9 inches, from the ends of the tube formed by the coils, the four-core cable a^1 is made solid with gutta percha, and over each of these parts of the cable is slipped a gutta percha cone *h*, so that it enters a short distance, say $\frac{1}{2}$ inch, into the tube f^1. The latter is then carefully tooled down on the cone *h*, and the latter in its turn is carefully tooled down for a short distance, say 3 inches over the solid part of the cable *a*. Finally, a second cone *i* of gutta percha is slipped over the first and tooled down, both on to the tube f^1 and on to the cable a^1. These various gutta percha parts are then autogenously united. Although lead and gutta percha have been described as encasing materials, india-rubber or other suitable substances may be used.

The claims are as follows:—



1. In electric cables into which are introduced induction coils, constructing these coils in the form of long and thin hollow cylinders, and arranging them to form a tube through which the conductors extend, flexible distance pieces being inserted between the coils, substantially as described.
2. In an electric cable having induction coils, such as is referred to in Claim 1, encasing the coils in gutta percha or like flexible insulating material, and joining this casing to the insulating material of the cable, substantially as described.
3. For making a joint between a casing, such as is referred to in Claim 2, and the cable, a cone or several cones slipped over the cable, and of such material that they can be joined to the said casing and to the insulating material of the cable, substantially as described.

We have consistently held the opinion that the difficulty in applying to submarine telephone cables the Heaviside-Pupin principle of inserting inductance or "loading" coils at intervals along the length of the cable was purely a mechanical one, which could be overcome by suitable design. Whatever may be the result of the present opposition to the grant of Messrs. Willoughby Smith and Granville's patent, the circumstances give a welcome sign that two of the most important manufacturers of submarine cables, the Telegraph Construction & Maintenance Co. (with which Messrs. Smith and Granville are connected), and Messrs. Siemens Bros. & Co., are devoting their attention to the problem. We have little doubt that in the near future submarine telephony will be greatly extended.

LOCOMOTIVES FOR THE BRITISH COLUMBIA ELECTRIC RAILWAY

THE following particulars of three locomotives supplied to the British Columbia Electric Railway are of interest. These locomotives, an external view of one of which is given in Fig 1, are of the articulated truck four-axle type, with one motor mounted upon each axle, so that there are eight driving wheels. The maximum rated tractive effort is 16,000 lbs. draw-bar pull, and the maximum instantaneous effort is 25,000 lbs.

A feature of special interest in the truck arrangement is that the body of the locomotive rests upon two four-wheeled trucks coupled together by a massive hinge which is flexible in the horizontal, but rigid in the vertical direction, thereby enabling the rear trucks to resist any tendency to tilt under the action of the forward truck, and *vice versâ*. The centre pins and cab-platform framing are not subjected to any longitudinal stress,

FIG. 1.—50-TON LOCOMOTIVE FOR THE BRITISH COLUMBIA ELECTRIC RAILWAY.

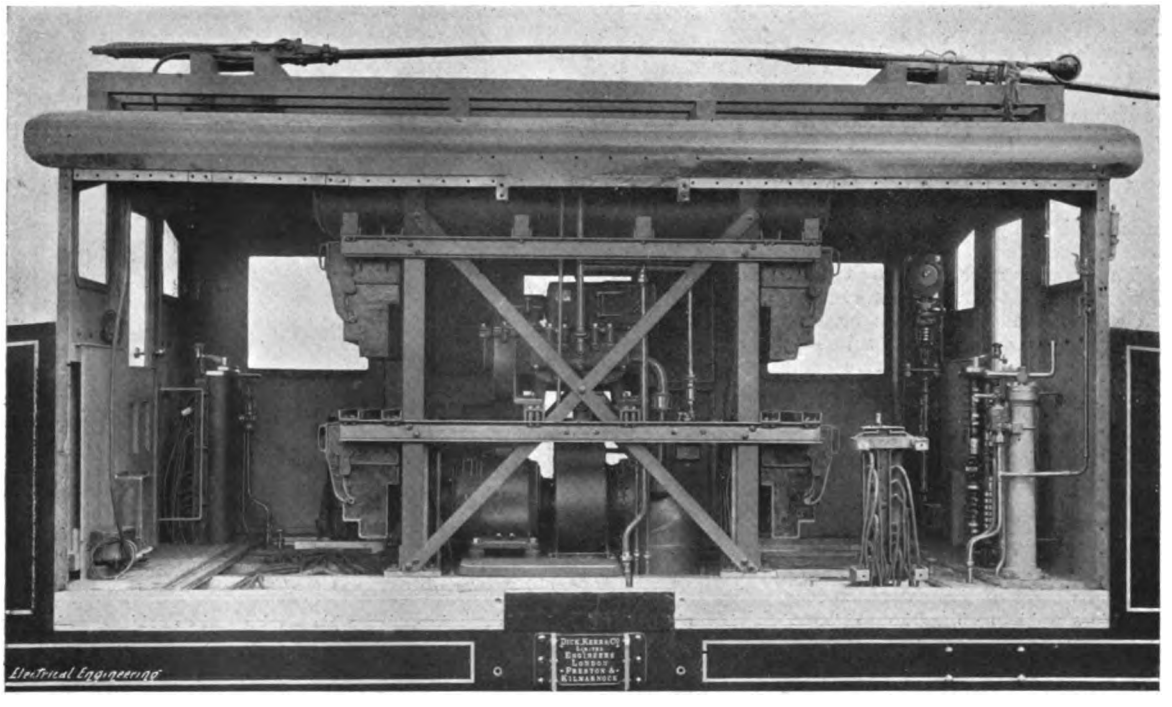

FIG. 2.—VIEW OF INTERIOR OF CAB OF 50-TON ELECTRIC LOCOMOTIVE.

Digitized by Google

except that due to the inertia of the cab when starting and stopping, the whole pull of the motors being transmitted direct from the motors through the trucks. Suitable arrangements are made to allow the trucks to radiate when passing round a curve. The spring suspension is of the locomotive type, the weight being carried by semi-elliptic springs resting on the journal box saddles.

A view of the interior of the cab is given in Fig. 2. This shows the two master controllers, one at each end of the cab, the contactor boxes, circuit breakers, switches, &c. The control equipment is of the standard Dick, Kerr multiple-unit type, with series magnets operating the various contactors. The resistances are placed in the sloping ends of the superstructure. The motor equipment consists of four D.K. 12A motors. When operating on a 600-volt circuit, each motor will give a tractive effort of 4,040 lbs. on the periphery of the 42 in. wheels and a speed of 15 m.p.h. at the one-hour rating. Each motor is fitted with reduction gear having a ratio of 3·64 to 1. The armature bearings of the motor are lubricated by oil rings which are specially designed to prevent flooding when running at high speeds, and the axle bearings are lubricated by a system of wicks which are immersed in oil wells. No grease is used as an emergency lubricator. The whole of the gearing of the motors is contained in a malleable-iron oil-tight gear box, which is provided with suitable stiffening ribs. It is supported by the axle bearing at one end, and by the pinion bearing and motor shell at the other end. The motors are designed and arranged for forced ventilation, the air being blown into the motor shell at the end farther from the commutator, and passing out at suitable openings provided at the commutator end. An external view of the motor is given in Fig. 3. The air for the forced

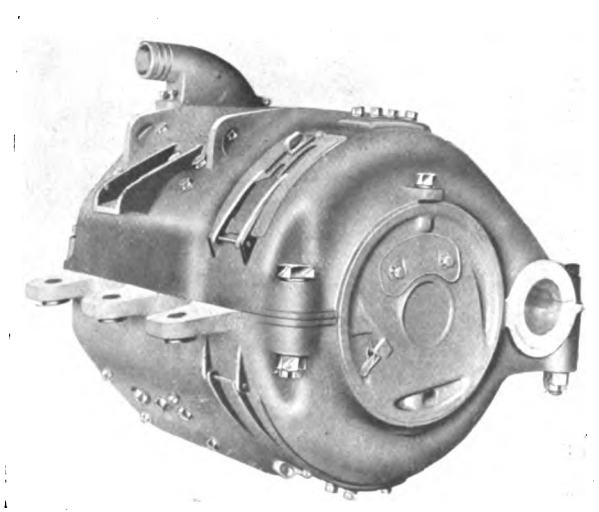

FIG. 3.—MOTOR OF 50-TON LOCOMOTIVE.

ventilation is obtained by means of an electrically driven centrifugal blower situated in the centre of the cab, as can be seen in Fig. 2. The controller for operating the motor of this blower is situated near the right-hand master controller.

In addition to the blower for the motors, there is an electrically driven air compressor with suitable air reservoirs for the air-brake equipment, the locomotive being fitted with combined direct and automatic air brake. The compressor for the brake equipment is mounted above the motor-driven blower in the cab. Two current collectors are provided, these being of the straight under-running trolley type, the current being collected from an overhead trolley line. The trolleys are equipped with retrievers. The following additional data are of interest:—Total wheel base, 24 ft. 6 in.; wheel base of each truck, 8 ft.; length overall, 35 ft. 7 in.; length of main cab, 16 ft. 5 in.; weight of cab above rail level, 14 ft. 1½ in.; width of cab, 9 ft. 8 in.; total weight of locomotive, 50 tons.

The locomotives were built and supplied by Dick, Kerr & Co., Ltd. The electrical equipment was manufactured at the company's electrical works at Preston, Lancashire, and the trucks and other mechanical portions at the company's general engineering works at Kilmarnock, N.B.

Corrections.—Two printers' errors occurred in our issue of last week. On p. 782, the late Mr. H. E. Harrison's name should have been given as Hugh Erat Harrison, and on p. 783 the last line of the fifth paragraph of the second column should read "since its discovery by Becquerel."

THE "PHONEHUSH"

AS the introduction of the present pedestal pattern of telephone and the corresponding wall-set is spreading and replacing the combined hand set, telephone users are missing the key in the handle of the older type of instrument. By releasing this key the microphone circuit could be opened momentary to permit of private conversation not intended for the ears of the person at the other end of the line. The expedient of placing one's hand over the mouthpiece of the instrument is a clumsy and not entirely efficient substitute, and the "Phonehush" is a device which has been invented by Mr. H. A. Cutmore, to effect what is required in a neater and more effective manner.

FIG. 1.—THE "PHONEHUSH" ATTACHED TO A PEDESTAL INSTRUMENT.

Fig. 1 shows the device attached to a pedestal instrument of the usual form; Fig. 2 is a general view. The apparatus is screwed on to the microphone case, beneath the mouthpiece, and a light steel spring, shown partly dotted in Fig. 3, is then in a position just below the grooved nut of the diaphragm binding post. When the key at the bottom is depressed, a shutter is lifted up behind the aperture in the mouthpiece, and at the same

FIG. 2.—THE "PHONEHUSH." TWO-THIRDS ACTUAL SIZE.

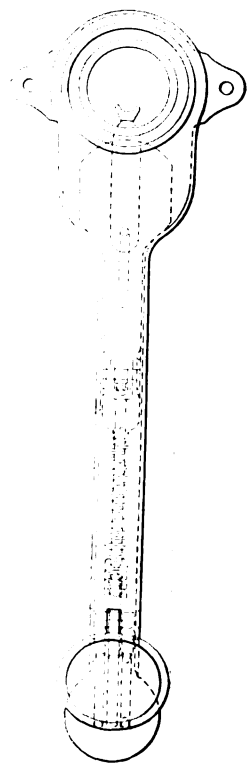

FIG. 3.—ELEVATION SHOWING WORKING PARTS.

Digitized by Google

time the hooked steel spring is pressed upwards lightly against the nut of the binding post, and so prevents the diaphragm from vibrating with the action of the voice.

We have tried the device in our own office, and have found it quite efficient in the prevention of overhearing, and also by no means troublesome to use. We are asked to state that the "Phonehush" is protected by master patents, that foreign patents have been applied for, and that the sole selling agents are Messrs. F. S. Dudgeon, Ltd., of 30 Great St. Helens, London, E.C.

THE "THEROL" ELECTRIC WATER HEATER

A NEW system of electric heating for bath water and other domestic purposes has been invented by Mr. G. G. Bell, electrical engineer to the Hammersmith Borough Council, and is being manufactured by Messrs. Spagnoletti, Ltd. (Goldhawk-road, London, W.). It will have one great attraction to central station engineers, viz., that it works at 100 per cent. load factor, or, in other words, that it is in constant operation 24 hours a day.

The construction of the heater is illustrated by the sketch, Fig. 1. A short coil of steel tube, through which the water

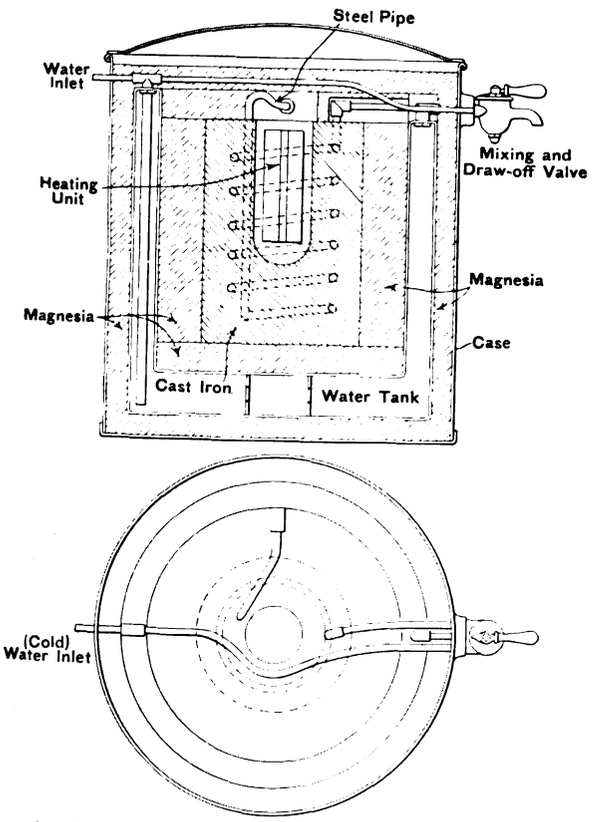

FIG. 1.—SECTIONAL SKETCH SHOWING CONSTRUCTION OF THE HEATER.

is to pass, is embedded in a heavy cylindrical block of iron some 2 cwt. in weight, which is cast round it. This is lagged all round with magnesia lagging, which is surrounded by a water-jacket, and the water-jacket is again lagged. In the centre of the iron cylinder is a heating unit, consisting of iron wires wound on a suitable former. The use of iron wires gives the advantage of the high positive temperature coefficient of this metal, so that its resistance is lower, more current is passed, and more heat evolved when the apparatus is cold, and the current is reduced automatically to a certain extent as the temperature rises.

The comparatively large specific heat of the iron and the water-jacket, and the thickness of the lagging, result in a considerable amount of heat being stored up, and, in fact, the makers estimate that, in ordinary use, no more than 10 per cent. of the heat generated will be lost. The cold water passes first through the water-jacket and then through the coiled pipe, and it is drawn off as required from a mixing tap at the other end of the pipe, which is also connected to the cold-water inlet and the water-jacket, so that by turning the tap round from the off to the full on position water of any temperature up to boiling may be obtained.

The iron and the coil of steel pipe assume quite a high temperature if left for a length of time without water being drawn —sometimes, we are informed, as high as 500° F. Naturally the water remaining in the coil becomes converted to steam under these conditions, but no excessively high steam pressure can be generated, as the connection through the water-jacket to the ordinary water cistern of the house is permanently open. The No. 1 size of "Therol" heater is 2 ft. in external diameter

FIG. 2.—GENERAL VIEW OF APPARATUS INSTALLED FOR BATH WATER.

and 2 ft. high. It requires 200 watts, and, we are informed, that, assuming that the initial temperature of the water is 50° F., it will supply, if required, 25 gallons of water per diem at 110° F., or, of course, correspondingly larger quantities at lower temperatures.

As the heat is stored and is not generated as required, it is, of course, feasible to switch the heater off during the time of the consumer's lighting peak, or during any short time that he may be using other heating or cooking apparatus, so that it is possible by the employment of a two-way switch to make the consumer's load factor practically 100 per cent. throughout. We understand that the makers are engaged in perfecting an automatic switch for this purpose. A disadvantage of the apparatus described, which, however, is one shared by the ordinary kitchen boiler and hot-water tank in any small house, is that if practically all the hot water obtainable is drawn off at any time, a considerable interval must elapse before hot or boiling water can be obtained again. To meet this, the makers will supply the apparatus fitted with a "superheater" and auxiliary tap, which enables a small quantity of boiling water to be obtained in a few minutes if required.

In the pamphlet which the makers issue, it is pointed out that, taking the price of electrical energy at £1 per kw. demanded, *plus* ½d. per unit, a price quoted by some supply companies for a power load, the cost of the energy consumed by the heater per annum will only be £4 9s. 8d. The makers also announce that they are making arrangements for hiring out the heaters to meet the case in which the consumer or supply company does not wish to buy them outright.

MUNICIPAL TRAMWAYS ASSOCIATION CONFERENCE, 1909

THE annual conference of the Municipal Tramways Association will be held in London from September 22nd to 24th inclusive. The president for the year is Mr. A. L. C. Fell, Chief Officer of the London County Council Tramways.

The conference will be opened on Wednesday, September 22nd, at 10.30 a.m., with a reception by the Chairman (Sir Melville Beechcroft), and members of the London County Council, at the County Hall, Spring Gardens, S.W. At 11 a.m. the Presidential Address will be delivered by Mr. Fell, after which the following Paper will be read:—"Medical Examination of Tramway Employees," by Councillor A. W. Chapman, Vice-Chairman of the Manchester Corporation Tramways Committee. At 1 p.m. there will be a luncheon at the invitation of the Chairman of the London County Council. In the afternoon the following Paper will be read:—"The Central Repair Depôt of the London County Council Tramways," by W. E. Ireland, Superintendent of Rolling Stock to the London County Council Tramways. The Association Dinner will be held at 7.30 p.m. at the Garden Club, Imperial International Exhibition, Shepherd's Bush, W.

On Thursday, September 23rd, there will be a meeting of the Manager's Section at 10.30 a.m., the full conference meeting at 11 a.m. in the Council Chamber. The following Papers are down for reading:—(1) "Some Comparisons of Continental and British Methods of Operating Tramways," by A. R. Fearnley, General Manager of the Sheffield Corporation Tramways; (2) "Current Consumption," by R. S. Pilcher, General Manager of the Aberdeen Corporation Tramways. The Chairman and

Digitized by Google

Members of the Highways Committee of the London County Council will entertain the Association at luncheon at the Holborn Restaurant at 1 p.m., and in the afternoon special cars will leave the Victoria Embankment (Waterloo Bridge) to convey the members and visitors to the Central Repair Depôt, and Greenwich Generating Station. At 9 p.m. the Mayor of London will give a reception at the Mansion House.

The Annual Business Meeting of the Association will be held at 10.15 a.m. on Friday, September 24th. At 1.55 p.m. a special train will leave Waterloo Station for Windsor. The party will be received by the Mayor and Corporation of Windsor in the Guildhall, where tea will subsequently be served.

A NEW ADJUSTABLE REAMER

MODERN engineering practice daily calls for greater accuracy of workmanship, and a greater refinement in tools of all sorts, especially in small tools for the final operations on accurate work. Of such operations, that of producing an accurately dimensioned hole is one of the most expensive and difficult, and to avoid the necessity of purchasing a large number of solid reamers, Messrs. Vickers Sons & Maxim, Ltd., of 32 Victoria Street, Westminster, S.W., introduced a new pattern of adjustable reamer into their Erith works, and are now placing this tool on the market, under the name of the "Vickers" One-lock adjustable reamer. An illustration of the complete tool is given in Fig. 1, while all the separate parts are shown in Fig. 2.

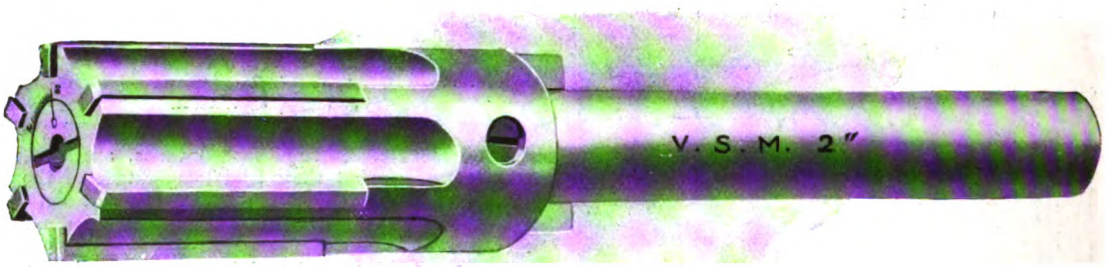

FIG. 1.—ADJUSTABLE REAMER COMPLETE.

The reamer consists of only three parts in addition to the blades, viz., the shell, the cam bolt, and the lock nut. In addition to these parts there is the arbor (either parallel or Morse taper), for supporting and driving the shell, the key for adjusting the reamer from the front end, and the box spanner for locking the adjustment when so made. The number of blades varies with the size of the reamer, but this number is always even, so that a micrometer may be used for ascertaining the size to which the reamer is set. The shell is made in one piece, as shown on the right of Fig. 2, and is bored and slotted to receive the cam bolt and blades. The cam bolt shown on the left of Fig. 2 provides the means for adjusting the blades. Around its circumference is arranged a set of cams in somewhat the form of the teeth of a ratchet wheel, one cam for each blade. The blades have their cutting and inner edges ground exactly parallel to each other, and the latter rest on the ratchet-like surfaces of the cam bolt. A projection of the inner edge of each blade engages with an undercut recess on the cam bolt, holding the blade rigidly against the hardened cam surface. On the front of the cam bolt is marked a zero line, and on the shell there are graduations to preserve the setting. The other end of the cam bolt is fitted with a nut, lying within the recessed upper end of the shell, which, when tightened with the box spanner, locks the adjustment of the blades. When adjusting the reamer, the cam bolt is revolved by inserting the key in the slot at the end, the blades are forced outwards by the cams, and the effective diameter of the reamer is thereby increased. Reversing the operation draws the blades inwards, but before tightening the lock nut, it should be ascertained that all the blades are actually bearing on the cam bolt.

When locked, this reamer is said to be as rigid as the solid pattern, and the adjustment can only be altered by the aid of the special box spanner, so that the reamers can be set in the tool room without fear of their being subsequently tampered with in the shop. The shell is heavily fluted, giving ample room for both lubricant and shavings. The only parts that require renewing are the blades. These are ground in special jigs, for although they may be re-ground in the usual way, the use of the special jigs ensures accurate and quicker results.

This reamer is essentially a finishing tool, and after drilling and opening out with a boring tool, the hole should be further opened out with a shell reamer before it is finished with the adjustable reamer. It is claimed that there should be no difficulty in producing any number of holes true to within one-thousandth of an inch with this tool, without the aid of skilled labour. It can be obtained for any diameter between $\frac{3}{4}$ in. and $6\frac{3}{16}$ in., the range of adjustment being 0·024 in. in the former case, and $\frac{1}{8}$ in. in the latter. The number of blades varies between six and fourteen. In all cases the actual minimum diameter of the reamer is slightly less than the rated diameter.

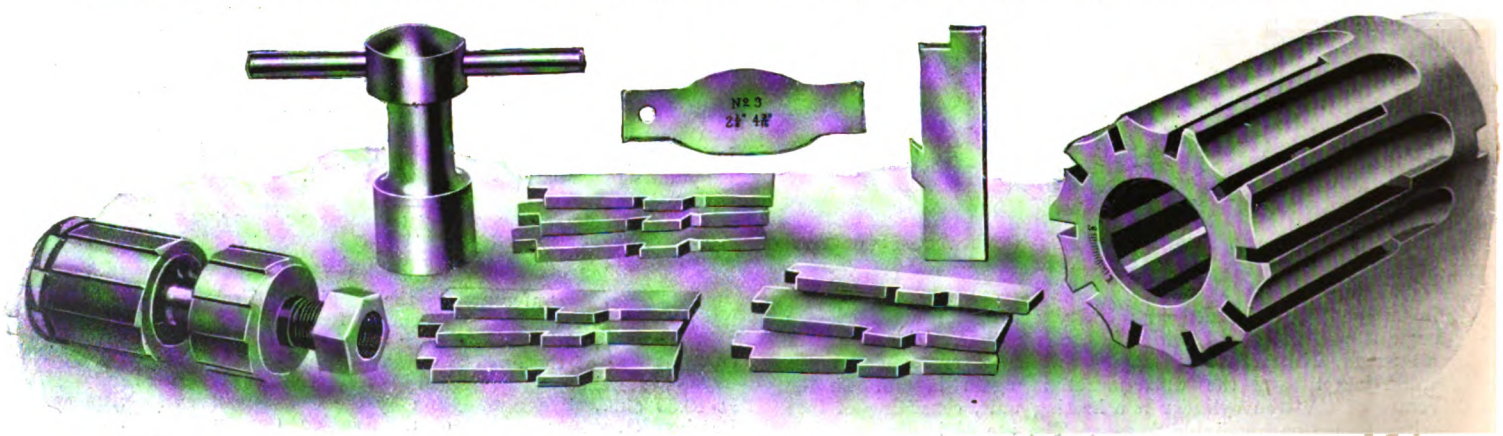

FIG. 2.—SEPARATE PARTS OF REAMER.

The Floods in Mexico.—The British Empire Trust Co. is advised by cablegram from Monterey (Mexico) that the damage done to the Mexican Light & Power Co.'s property by the floods is not very serious. The overhead wires in the San Lusito suburb are down, and also several poles in the city, but the damage to the plant is slight. The lighting service is continued with only a few interruptions during the day. The electrical tramway plant is not damaged, although the service was interrupted somewhat. Both the lighting and tramway services will be in full operation within twenty-four hours after the river has gone down.

THE MANUFACTURE OF TUNGSTEN FILAMENTS

Amendment of the Fundamental British Patent Specification

THE Comptroller General of Patents has allowed the Wolfram (Tungsten) Metal Filament Lamps, Ltd., the owners of the Just and Hanaman and other patents for the manufacture of tungsten filaments, to make certain amendments to the specification of British patent No. 23,899 of 1904. This patent, it may be remembered, was referred to by Mr. Hugo Hirst in his Institution Paper on Osram lamps, as the first English patent describing the manufacture of pure tungsten filaments. The specification has been amended in three important respects. In the first place, all references to the metal molybdenum have been deleted, so that the patent now refers to tungsten filaments only; secondly, the description of a chemical process for substituting tungsten or molybdenum for the carbon of purely carbon filaments or of filaments containing carbon, by raising the filaments to incandescence in an atmosphere of vapours of oxyhalogen compounds of tungsten, or molybdenum, together with a little free hydrogen, has been taken out; and thirdly, a disclaiming clause has been added, taking note of certain prior German and British patents.

The patent as amended reads as follows:—

We, Dr. Alexander Just, chemist, of 11 Mollardgasse, and Franz Hanaman, chemist, of 16 Phorusgasse, both in Vienna, in the Empire of Austria, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention has reference to incandescent electric lamps, and has for its object to produce an incandescing body composed of wolfram (tungsten). This metal has been applied to carbon filaments in the form of a coating for incandescent electric lighting purposes. The object sought to be attained was to prevent the disintegration of the carbon. Incandescent lamps of this construction were only employed to a limited extent, however, mainly because a mere coating is not able to prevent the vapour tension of the carbon, which depends only upon the temperature, and because tungsten carbide necessarily forms at the points of contact between the carbon core and the coating of tungsten, and these reactions alter the chemical composition of the incandescing body.

Now, in accordance with the present invention, it is possible to produce filaments consisting of pure tungsten, and which do not, therefore, present the defects referred to above. For the manufacture of filaments of this kind, finely divided tungsten or tungsten compounds, such as tungstite, tungstic acid, or tungstic sulphide, is mixed with an organic binding medium, such as collodion or a solution of cellulose in chloride of zinc or cupreous ammonia oxide or the like, from which mass filaments are formed in the usual manner, and are then carbonised, in some cases after denitration has previously been effected. The filaments so produced and consisting of tungsten and carbon are then submitted to the following further treatment: First of all the carbon, which has only served as a binding medium, is removed, by subjecting the filaments to the passage of current in an atmosphere of steam and hydrogen, and thus raising it to a high temperature. By this process the carbon is completely oxidised so as to form carbonic oxide, and a filament of tungsten is left. These filaments are then rendered uniform in a manner similar to that employed in the treatment of the usual carbon filaments, by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen, whereby the tungsten deposited equalises the filaments. The filaments which have been rendered uniform in this way are then sealed in glass bulbs in the usual manner, and these latter are exhausted.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we wish it to be understood that we are aware of the German patent No. 154,262, and of the English patents No. 19,785 of 1898 and No. 20,277 of 1904, and do not claim the inventions described and claimed therein, but we declare that what we claim is:—

(1) Incandescing bodies for incandescent electric lamps consisting of tungsten manufactured substantially as and in the manner hereinbefore described.

(2) Process for the manufacture of incandescing bodies in accordance with Claim 1, characterised by the fact that the tungsten or compounds of this metal are mixed with organic binding media, formed and carbonised, whereupon the carbon is removed chemically substantially as described.

The following are brief abstracts of the three prior patents referred to in the disclaiming clause:—

The British patent No. 19,785 of September 17th, 1898, was granted to Carl Kellner, of Vienna, and is for a process of manufacturing incandescing bodies of thorium, titanium (pure or nitride of titanium), chromium, wolfram (tungsten), or of alloys of such metals, the resulting bodies or filaments being oxidised at the surface. A mixture of oxides of such metals with a small quantity of graphite is proposed as an alternative to the pure metals. In the first case, the metals are mixed in the form of dry powder, without any binding agent, and moulded under pressure into the desired shape, and the necessary outer layer of oxide is produced by raising to incandescence in the atmosphere, by immersion in acid, or by electrolytic means. In the second case, the powdered oxide of the metal is mixed with cellulose, and the product raised to incandescence in a vacuum or in the presence of hydrogen until the contained carbon is converted into graphite of a high density. A method of fusing leading-in wires into the ends of the moulded filaments with the aid of the electric arc is also covered by this patent.

The German patent No. 154,262 of April 15th, 1903, was taken out by Drs. A. Just and F. Hanaman, of Vienna, and describes the process of manufacturing filaments of tungsten or molybdenum corresponding to that which has been deleted from the British patent as mentioned above—namely, the raising to incandescence of a carbon filament in an atmosphere of oxyhalogen compounds of tungsten or molybdenum, together with a little free hydrogen, the carbon being replaced by tungsten or molybdenum, respectively.

The third patent is the British patent No. 20,277 of 1904, which was taken out in the name of C. D. Abel, being a communication from abroad by the Siemens & Halske Akt.-Ges. It is for incandescing bodies of molybdenum, thorium, titanium, tungsten, or zirconium, or alloys of these metals, free from any non-metallic substances, and in the form of drawn wires. The specification states that although the wire may be drawn from pieces of compressed metal powder or from rods formed by sintering powder, it is difficult to avoid the formation of cavities and cracks in this process, and that the better way is to heat an oxide of the metal in a vacuum or in the presence of an inert gas, removing the gases evolved, until there is only pure metal in a fused state which is then cooled and drawn into wire.

THE PACIFIC CABLE

THE report of the Pacific Cable Board for the year to March 31st, 1909, shows that the total receipts amounted to £113,093, and the expenditure to £96,436. The sum of £16,657 was thus available for reduction of the amount (£77,544) contributed annually for interest and sinking fund on the capital advanced by the National Debt Commissioners, and the sum of £62,362 has been contributed by the Governments associated in the enterprise. The receipts exceeded those of the previous year by £2,933. Miscellaneous receipts during the past year amounted to £2,031, whereas during the previous year they amounted to £522 only. The actual increase on account of traffic is thus reduced to £1,425. This shows an increase of £1,458. The forecast of the Board's revenue contained in the annual account for the year ending March 31st, 1909, was exceeded by £5,093, while the actual expenditure was £3,586 below the estimate.

The preliminary forecast of revenue and expenditure for the year ending March 31st, 1910, shows an estimated excess of expenditure over receipts of £13,045.

There were, during the past year, serious interruptions of the Canadian land line service on many occasions, and the Board's interests were, in consequence, adversely affected, not only by the considerable amount of traffic diverted to the Eastern route, but also by the loss of prestige caused by the failure of the Board's system to deal with the traffic entrusted to it. For several months some delay was caused almost daily to the Board's Australian traffic, owing to the faulty condition of the Southport-Sydney line.

Experiments with improved methods of increasing the duplex speed of the Bamfield-Fanning section of the system met with great success, and this cable, laid with the anticipation that the speed would not, in actual practice, exceed 65 letters a minute, is now daily working at the speed of 90 to 97 letters a minute. As the traffic-carrying capacity of the entire route is ruled by the results attainable on this section, this increased speed, which has been attained without risk of damage to the cable, greatly improves the revenue-earning capabilities of the Board's system.

On the death of Mr. Reynolds, which was recorded in the last annual account, the Board decided to abolish the post of General Manager, and to redistribute the duties between a London manager and secretary, and a manager, in the Pacific who should be the Board's representative in Australasia, and should exercise more immediate control and supervision over the staff in the Pacific. To the post of London manager and secretary, Mr. A. S. Baxendale was appointed, and that of manager in the Pacific was filled by the promotion of Mr. Milward, chief electrician, who continues to perform the duties of that office.

REPORTED REMOVAL OF A CABLE WORKS FROM LONDON

IN last Friday's *Evening News* it was stated that a firm of cable manufacturers had decided to transfer part of their business to Peterborough, where they would employ about 1,000 hands. The paragraph gives also the following additional particulars:—

They have been offered a site of twenty-five acres on advantageous terms, and as Peterborough is a good railway centre every facility for the carrying on of the business will be available. The company will require a minimum of 500,000 units of electricity a year, increasing to 1,500,000 units. This will necessitate an enlargement of the Peterborough Electric Works. It is expected that the removal of the firm will take place early next year if the negotiations, which are in an advanced stage, are completed in time.

The cable manufacturers referred to are in all probability the India-Rubber, Gutta-Percha & Telegraph Works Co., Ltd., of Silvertown, but the announcement is at any rate somewhat premature. The company has for some time past been looking out for a suitable site, to which to remove a part of their works, and they have, we believe, made inquiries at Peterborough, among other places. We understand, however, that nothing definite has yet been decided upon.

The firm pay some £7,000 a year in rates to the West Ham Corporation in respect of their works at Silvertown, and there is no doubt that economies could be arrived at by a transfer of a portion of the factory to another district. While obviously a situation on the River is necessary for their submarine cable department, and the Thames is probably a more convenient centre for this than would be the Clyde, the Tyne, or the Tees, submarine cable manufacture is only a branch of the company's business. The firm's manufactures include electric light and power cable, as well as telegraph and telephone cable, and they also cover a wide field in electrical apparatus and instruments, and the manufacture of mechanical rubber—including golf balls—represents a large proportion of their business. It is seen, therefore, that for a large part of their manufactures a good site on a main line of railway would be as advantageous as the present one on the Thames.

The existing works are electrically driven, but at present they have their own generating plant, and do not take a supply from the West Ham Corporation. If a portion of the works were moved, however, it might quite well be found desirable to take electrical energy from the public supply station if suitable arrangements could be made in the district to which the works are transferred.

WIRELESS TELEGRAPH NOTES

The Dover-Calais Channel steamers are being equipped with wireless telegraph apparatus, and the first to be so dealt with is the turbine steamer *Empress*. It is stated that all the South Eastern and Chatham Railway Co. passenger steamers on the Dover and Boulogne routes are to be similarly equipped.

It is announced that an agreement has been come to between the General Post Office and Marconi's Wireless Telegraph Co., whereby the former will acquire the coast land stations in the United Kingdom. The company is to retain the Transatlantic stations of Poldhu (Cornwall) and Clifden (Ireland), but the Post Office will take over the stations at Caister, Crookhaven, Liverpool, the Lizard, Niton, North Foreland, Rosslare, Withernsea, and Holyhead. All future coast stations in the United Kingdom will be erected by the Post Office, but there is no immediate intention of erecting additional stations. Although the shore stations will in future be worked by the Post Office, the company will work the ship stations and retain the receipts therefrom. The terms of purchase of the existing land stations have not been made public. The agreement gives the Post Office the right to use the Marconi system for purposes of inland transmission for a period of 14 years. In answer to a question in the House of Commons on Tuesday, the Postmaster-General stated that the announcement in the daily papers of this agreement was premature and did not emanate from the Post Office. The negotiations were to a certain extent contingent on the success of somewhat similar negotiations with Lloyd's, which were not yet completed. He proposed to make a statement on the subject to the House of Commons when the arrangements were finally completed.

The disappearance of the *Waratah* has led to the suggestion that wireless telegraph stations should be erected around the South African coast, and certainly, in the first instance, at Cape Town and Durban.

FAILURE OF AUTOMATIC SIGNAL ON THE METROPOLITAN RAILWAY

LIEUT.-COLONEL DRUITT has now presented to the Board of Trade his report on a collision which occurred on August 5th last between two passenger trains at the Moorgate Street Station of the Metropolitan Railway. A train was standing at the platform waiting for the starting signal to be lowered when another train ran into it from the rear. Three passengers were slightly injured, but no carriages were derailed, and the damage to the rolling stock was slight. That no further damage occurred was fortunate, but the nature of the accident was a serious one, as automatic signals are employed, and the evidence conclusively showed that the cause of the accident was the failure of a signal. The driver of the rear train said the signals were in the "clear" position, and he could not see the train standing in the station until he was about 50 yards away from it, as the line is on a curve, and a sub-station building further impeded his view. He had, in fact, already switched off the current before he saw the station. On seeing the train he applied the emergency brake and reversed the motors. The automatic Westinghouse brakes acted well, and the train was slowed down considerably. Evidence was given to the effect that this particular signal had failed to come off on certain previous occasions, but had never before failed to go "on" to the danger position.

The system of signalling in use is known as the Johnson All-Electric Automatic and Semi-Automatic Power Signalling System. It was installed by the McKenzie, Holland, and Westinghouse Power Signal Co., Ltd., and is still in their hands for maintenance. It was brought into use at Moorgate Street on July 4th last, but has been in operation at Praed Street Junction since July 26th, 1908. A description of the system was given in ELECTRICAL ENGINEERING of June 11th, 1908 (Vol. III., page 877). The system is similar to that in use on the District Railway, except that the points and signals are electrically-driven through an oil transmission instead of by compressed air. An intermediate gearing is placed between the electric motor and the signal arm, known as the Johnson oil motor. This consists of a cylinder containing a piston which actuates the signal arm. When the arm is to be lowered, oil is pumped into the cylinder by a rotary pump worked by the motor through a non-return valve, and to put the signal to danger, another valve is opened, and the oil released, when the counterweight causes the arm to rise. This release valve is normally held open, but is closed by a solenoid when a "line clear" signal is required at the same moment that the pump motor starts. The solenoids controlling the motor and actuating the release valve are worked by a track circuit, dependent on the position of the train, so that the signals are entirely automatic. A failure of current opens the release valve and causes the signal to fly back to danger.

From the evidence given by Mr. H. G. Brown, the chief engineer of the McKenzie, Hollaud & Westinghouse Power Signal Co., it appeared that the track circuit was in proper working order, and that the current was cut off the release coil when the train occupied the section. The signal remained in the clear position, however, due to some cause within the mechanism itself, probably owing to an accumulation of sediment in the oil, which made the release valve stick. By suitable re-designing, Mr. Brown stated, all possibility of a recurrence of this will be removed. All the signals actuated in a similar manner (18 or 19 in number) will have new valves fitted to the oil machine. In the meanwhile all these signals are being watched to see that they go to danger after the passage of a train, and they will be watched until the contemplated alteration in the pattern of valve has been effected, and found by practical working to be satisfactory.

Telegraph Traffic.—The French Cable Co. has suffered an important breakdown of its West Indian connecting link, as the Puerto Plata-Martinique cable ceased operating on the 2nd inst. —The Cayenne-Salinas, Paramaribo-Cayenne, Paramaribo-Martinique, New York-Haiti, and the cable before mentioned have all failed during the current year, and, although the company possesses a repairing steamer stationed in the Caribbean Sea, the repairing bill must be a very heavy one.—On August 31st a breakdown occurred between Bagdad and Bassorah, while communication between Rabat and Mogador was restored. The line between the first-mentioned places was restored on the 1st inst.—The line between Saigon and Bangkok was down for a short while on the 1st inst.—The Indo-European Telegraph Co.'s system between Kertch and Soukhoum Hale failed on the 2nd inst., and between the 2nd and 3rd inst. the Bagdad-Bassorah line followed suit. On the 5th inst. the Bagdad-Bassorah line was again in trouble.

ENGINEERING DAY AT THE WHITE CITY

A NUMBER of engineers from all parts of the country assembled at the Exhibition at Shepherd's Bush on Saturday in response to invitations issued by a special committee formed from members of the several engineering committees of the Imperial International Exhibition. The visitors were conducted round the grounds and allowed to inspect the structural features and operating mechanism of the various amusement devices, and the sub-station for the distribution of electrical power for driving the machinery and for lighting. Special demonstrations in connection with the exhibits in the machinery hall had been arranged for, and six Papers were read in the Congress Hall.

The first Paper was Mr. A. Steiger's, on "Water Power and Turbines." Mr. W. B. Bryan took the chair.

After referring to the existing water-power plants in Scotland, Wales, and Ireland, the lecturer asserted that there was in all about one million horse-power of water-power available in the United Kingdom. The greater part of this was in small amounts, and the average cost of developing it could be taken as about £40 per b.h.p. There were no great difficulties in the way of utilising this power, however, and the cheap electrical power produced would be of great value in the steel and iron industry, which had entered into a new stage with the introduction of the electric furnace. The capital cost of hydraulic works was very heavy as compared with a steam or gas plant of equal output, but the running costs were so low that very cheap power could be produced. A scheme had been promoted in Switzerland to make possible the navigation of the Rhine between Basle and Lake Constance by the erection of a series of weirs and locks. This would render available some 150,000 h.p. of water-power, and works were to be erected at Laufenburg and other places. The total cost of the work would be over six million pounds sterling. Mr. Steiger then referred to the high efficiency of the modern water-turbine, namely, from 75 to 80 per cent., and described the different types. The impulse type was most suitable for high falls, and the pressure or reaction type for low falls. Pelton-impulse turbines had been constructed in varying sizes up to 8,000 h.p. In Canton Valais, there were some operating on a fall of 3,000 ft. These ran at 1,000 r.p.m., and were only four feet in diameter. The lecturer exhibited some curves showing the excellent speed regulation obtained with the Engelberg 2,500 h.p. turbines. On throwing off over 2,000 h.p. the speed only rose 7 per cent., and after three seconds fell to only 4 per cent. above the normal full-load speed. Finally, a number of low-fall installations were described, and the methods of overcoming the difficulties associated with falls of varying height referred to.

The next Paper was by Mr. John McLaren, member of the council of the Institute of Marine Engineers, and was entitled, "The Extended Uses of Electricity on Board Ship." Sir F. Flannery, Bart., took the chair.

Mr. McLaren's Paper dealt chiefly with a proposal to drive the whole of the auxiliary machinery of large ships, including all cargo winches, hoists, capstans, pumps, ventilating and refrigerating machinery, &c., by electric motors supplied from a central generating plant, and to use electric power exclusively for the lighting and heating of cabins and passages and for cooking. After exhaustive tests the author arrived at the conclusion that the efficiency of the steam generating plant now generally in use was only 25 per cent. There are of necessity a number of long steam pipes with very great loss by radiation, and, as most of the auxiliary engines work non-condensing, there is a great waste of water. Mr. McLaren suggested the use of a suction-gas generating plant. He described a typical 300-h.p. plant, consisting of a gas producer and coke scrubbers weighing some 19 tons; a vertical multiple-cylinder, single-acting engine working on the Otto four-cycle principle, and running at 200 r.p.m.; and a three-phase alternator generating at 250 volts, with a frequency of 50. The field system should be built up on the rim of the gas-engine flywheel. Squirrel-cage induction motors would be used for the smaller machines, and motors with wound rotors and starting resistances for the heavier machinery and in cases where a large starting torque is required. Where a considerable range of speed variation is required, Mr. Durtnall's "Paragon" system of control for squirrel-cage motors, in which the frequency of supply is varied, could be adopted.

The equipment of a large dredger now being built, and provided with electric driving gear by Mr. Durtnall, comprises a 200-h.p. Diesel engine running at 300 r.p.m. and driving six small four-pole machines coupled together in line. The first machine will be a three-phase 350-volt generator with a frequency of 10, and the other five will be rotary frequency changers. The rotor of the first will be fed with the 10-cycle current, and the stator will deliver 20-cycle current, which in turn is fed into the stator of the second frequency changer, the current generated in the rotor having a frequency of 30. In the same way a 40-cycle current is generated in the stator of the third, a 50-cycle current in the rotor of the fourth, and a 60-cycle current in the stator of the last machine. The bucket-chain drum, main winch, rotary pumps, ladder winch, revolving screen, and belt conveyer are all driven by squirrel-cage induction motors provided with special controllers, by which the eight-pole motors can be run at speeds of 146, 290, 437, 582, 730, and 874 r.p.m. in either direction without the use of controlling resistances by supplying current at the six different frequencies. When reducing the speed of any machine, the motor is taken off, say, the 60-cycle supply and connected to the 50-cycle mains, and while falling in speed supplies power to the generating set. As the motors are situated fairly close together, the necessity of having a set of mains for each of the six frequencies will not cause serious inconvenience.

Returning to his typical 300-h.p. plant, the author pointed out that the lighting circuits would be balanced between the three phases and the neutral of the star-connected generator, and the ship would be heated by suitable patterns of electric radiators, and cooking could also be done with electrical apparatus. He then compared the efficiency of the suction-gas plant with that of a similar steam plant, and arrived at the conclusion that the gas engine requires 0·85 lb. of coal per b.h.p.-hour as against 2 lbs. for the steam engine. With regard to distribution of power and utilisation in the auxiliaries, the losses with electrical apparatus would be about 20 per cent. as against over 75 per cent. for steam. The weight of a 300-h.p. gas engine of the type described would be some 30 tons, so that the total weight of the plant would be 49 tons. On account of the low coal consumption and higher efficiency of the auxiliary plant, the bunker space required would be only one-quarter of that required in the case of steam-driven auxiliaries. Continuing, Mr. McLaren mentioned that the cost of upkeep of the 300-h.p. producer plant would be £10 or £11 per annum, and finally he gave some comparative figures of the steam- and gas-engine equipments of the gunboat *Rattler*, which show a saving of fuel to the amount of 50 per cent., and of weight 25 per cent., with the gas plant.

After a Paper by Mr. H. Ruck-Keen, on the treatment of marine boilers on long voyages, Mr. P. R. Allen gave a lecture entitled, "Large Gas Engines," the chair being occupied by Mr. Dugald Clerk.

Mr. Allen, who is responsible for the large gas-engine installation of the Castner Kellner chemical works at Weston Point, commenced his lecture with a brief history of the development of the gas engine, and then described some of the leading makes of the present day, illustrating his remarks with a series of lantern slides. The engines of the Deutz Co., the Augsberg & Nurnberg Co., Messrs. Ehrhardt & Sehmer, Messrs. Haniel & Lueg, and also Messrs. Richardsons, Westgarth & Co., the British licensees of the Delamere Debouteville system were mentioned, and a series of photographs of Mather & Platt engines were also shown. The Premier engine (see ELECTRICAL ENGINEERING, May 6th, 1909, p. 415), in which effective scavenging is obtained with a four-stroke cycle, was also illustrated. After describing the different patterns of suction-gas producers, the lecturer referred to the value of sulphate of ammonia recovery plants, and also showed an illustration of a plant consuming peat, which has been put down by the Power Gas Corporation Co. in Norfolk. Finally the large installations at Bruckhausen, Germany, and Gary, U.S.A., where 24,000 h.p. and 65,000 h.p. of gas-engine plant are installed respectively, were referred to.

The two following lectures by T. R. Ablett and C. A. Ablett respectively, dealt with "snapshot" drawings and perspective drawings of machinery for engineers and architects. The value of drawing machine details from memory as a method of developing the powers of observation of engineering students was emphasised in the first lecture, and a new system of simple perspective drawing was described in the second.

While the above lectures and Papers were being read, a number of the visitors were taken round the grounds to inspect the mechanism of the principal amusement devices.

The appearance of the "Flip-flap," with its two lattice steel counter-weighted arms, each moving through an angle of a little over 180° in opposite directions, and carrying at their extremities cages containing 48 passengers each, is too well known to need description. The centre of the main shaft is 25 ft. above the ground, and the length of each arm from the main shaft to the

Digitized by Google

pin on which the passenger car swings is 150 ft. The foundations consist of 900 tons of reinforced concrete on a bed of 64 piles. Each arm weighs 182 tons, made up of 48 tons for the loaded car, 50 tons of steel work, and a concrete balance weight of 120 tons. The driving gears of the arms are connected together by a pair of central bevels driven by a 100-h.p. D.-C. shunt-wound motor, supplied by a special 500-volt feeder from the exhibition sub-station. It drives the vertical bevel shaft through worm-gear. Each driven shaft carries a pair of sprockets, from which the power is transmitted by chains to the triple reduction spur gearing on each side of each arm, and differential gears are provided to ensure equality of drive on both sides of each arm. The total ratio of reduction is 1,500 to 1, and the total weight of the machinery 75 tons. Jockeys are fitted by which the slack of the chains can be taken up. An important feature of the gear is the set of brake drums on the first pinion shaft of the spur gear, upon which wooden brake shoes are applied by the four solenoid brakes whenever the current is cut off or fails. These brakes are fitted with dashpots, so that they can be taken off instantly but only applied gradually. A locking gear is fitted to lock the arms when passengers are entering or leaving the cages. The locking bolts are connected to contacts which control the circuits of green and red signal lamps in the driver's cabin, and there are also similar signal lamps on the platforms. Further safety devices consist in limit switches preventing the driver overrunning the platforms, and emergency switches on both platforms by which the motor can be stopped and the brakes applied at any time independently of the driver. The apparatus in the driver's cabin comprises, besides the actual drum type controller, a solenoid operated main switch, which plays an important part in the system of control. Suppose now the arms are both locked and passengers are going on board, the red signal light circuit is closed at all points. The attendant at one end draws his locking bolt when he is ready; this puts out the red lights and warns the driver, and also closes contacts at that end in the green lamp and solenoid circuits, but these two circuits are not completed until the attendant on the second platform also withdraws his bolt. When this is done the green lamps light up, and the solenoid switch in the main motor circuit is closed ready for the driver to use his controller. He then starts up the motor and runs the trip. During the trip the motor can be stopped independently of the driver in the following ways: By a temporary failure of current, by an emergency switch, by an improper closing of one of the locking bolts, or by the working of the limit switches. In none of these cases can the machinery be restarted except by bringing the controller back to the zero position. The way this is ensured is by arranging that the solenoid switch only has its full current through its coil when the controller is in the off position; in all other positions a resistance is in the solenoid circuit, which brings down the current to a value sufficient to hold the armature on but not to pick it up. The main solenoid switch is provided with carbon contacts and magnetic blow out, suitable for 200 amperes at 500 volts.

The "Water Whirl" consists of a circular trench 10 ft. wide and 140 ft. in diameter to the centre line. It is designed to carry two groups of six boats, each having seating capacity for 20 passengers. These boats are towed by means of horizontal bars attached to a revolving ring, partially supported on six massive flywheels, each with a 9 in. face. When these wheels are rotated, they carry with them the ring by reason of adhesion. Each of the flywheels is driven by a 22 h.p. motor, and the six motors are controlled from a central cabin. A semaphore and bell signal system is provided. The whole of the machinery is below ground with the exception of the towing arms.

The device called the "Witching Waves" is operated by a 20-h.p. motor, which is geared to a special mechanism for produring the undulating motion of the sheet steel surface on which the boats run.

The racing motor track comprises three endless tracks, each 780 yards long. A maximum speed of 15 miles per hour is obtained. The cars are controlled by the persons driving them, and are electrically driven by means of 4½-h.p. compound-wound motors. The live rails are of copper, and are each divided into seven sections between the finishing and starting points. The three shorter are under the control of the brakesman; the others are controlled from the dynamo-room, from which current is supplied at 120 volts. An earthed copper return is also provided. Twelve cars can be run at once on three tracks.

The cars of the scenic railway are hauled up the gradients by means of wire ropes which pass over drums driven by a suction gas engine.

The trains of cars of the mountain railway are driven by electric motors, the current being collected from an insulated third rail. Powerful brakes are fitted, and an elaborate system of electric signalling is also provided. The length of the track is 1⅛ miles, and the average speed attained 12 m.p.h. The maximum grade is 40 degrees.

In the spiral railway, the elevation of the cars is effected by a rotating centre, which draws them up a spiral incline. The central structure is rotated by a 26-h.p. gas engine.

Messrs. Joseph Baker & Sons' bakery and confectionery exhibit includes a number of electrically-driven machines, power being supplied by a 60-h.p. gas engine generating set.

One of the most interesting devices is the "Submarine Railway," which is new this year, and offers many features of engineering interest. The four "boats" are built up of $\frac{5}{16}$ in. steel plate in the shape of submarines, with ½ in. glass windows. Each boats holds 30 passengers, and has a displacement of 20 tons. The four boats are drawn round a circular track which dips four times under water. Bogies with wheels above and below the rails are provided, as, of course, the boats have a strong tendency to rise when under water. An endless chain, the links of which are formed to the curvature of the track, runs along the centre of the track, being guided by rollers at the inner side and on top. It passes over four sprocket wheels, one at the top of each rise, each of which is geared to a 50-h.p. motor. The boats are attached to the chain, and are thus hauled round the track. The most power is taken when the boats are descending into the water, on account of their buoyancy. When in the deepest part, the passengers sit nearly 10 ft. under water. The entrance to the boat is by way of a trap-door, which is bolted down water-tight. Two funnel-like exits, which are not submerged, are also provided in case the chain should break when the boats are under water.

The two electrically-driven pumps for the cascade in the Court of Honour are of the "Rees-Roturbo" pattern, direct-coupled to 30-h.p. D.-C. motors. Each pump delivers normally 3,000 gallons of water per minute, against a head of 25 ft. The total amount of water delivered by the two pumps is some 16,000 tons per day of 10 working hours.

The sub-station in the machinery hall contains two 400-kw. Bruce, Peebles—La Cour cascade motor-converters, and a group of transformers. Full particulars of the lighting and power arrangements at the Exhibition were given in ELECTRICAL ENGINEERING, May 7th, 1908, Vol. III., page 687.

In the course of the afternoon a reception was held by the Lord Mayor, Sir G. W. Truscott, and in the evening some 250 of the visitors assembled at a banquet held in the Garden Club, when the chair was taken by the Hon. A. Stanley. Among those present were Sir Fortescue Flannery, Sir Thomas Pile, Sir John Cockburn, Mr. W. Worby Beaumont, Mr. Dugald Clerk, Mr. W. B. Bryan, Prof. Bauerman, and Captain H. Riall Sankey. From the opinions expressed by those present at these functions, it is probable that a similar meeting of engineering institutions and societies will be held annually.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

HIGH-SPEED MOTORS.—A pamphlet issued by the Lahmeyer Electrical Co., Ltd. (109-111 New Oxford Street, London, W.C.), contains an interesting description of a number of examples of high-speed motors for large outputs. These motors have relatively small diameters in order to keep down the peripheral speed, and correspondingly greater lengths in an axial direction than motors for normal speeds. A fan mounted on the shaft and ventilating ducts assist the cooling of the windings, the cooling surfaces being naturally smaller in such high-speed machines. The illustrations show motors of this type coupled to centrifugal pumps and blowers in mines and smelting works. In order to render the motors suitable for working in damp places, the windings are immersed in boiling varnish and dried in a vacuum oven, this treatment being repeated several times, until a thick durable coating of varnish is obtained, as well as a thorough impregnation of the insulation. One illustration shows three motor-driven turbo-blowers of the Rateau type at the Mansfield Co.'s smelting works at Eisleben, Germany; the 125-h.p. motors run at 3,000 r.p.m., direct off the 3,000-volt three-phase mains.

DRY CELLS.—The Wright Sales Co. (Exchange Chambers, Briggate, Leeds) are issuing a booklet giving full particulars of several patterns of dry cells, medical coils, portable lamps, and other electrical apparatus. The "Red Seal" dry battery, for which the company are the sole British agents, is claimed to be especially suitable for ignition purposes and other work requiring high amperage.

THE ELECTRICAL CO.'S SPECIALITIES.—An abridged price list is to hand from the Electrical Co., Ltd. (122-124 Charing Cross Road, London, W.C.). This is a book of about 150 pages, giving a *résumé* of all this company's electrical apparatus and fittings, with lists of sizes and prices. The first 30 pages are devoted to photographs of electrical installations put down by the company, turbo-generators, large machines, transformers, and special applications of electric power. This is followed by abridged lists of all the company's specialities, including motors of all types, fans, wiring fittings, switchgear,

Digitized by Google

instruments and meters, arc lamps, metal filament lamps, special carbon filament lamps, &c. An index is provided.

WIRING CONDUIT.—The Sun Electrical Co., Ltd. (118 and 120 Charing Cross Road, London, W.C.), have sent us their latest catalogue relating to the "Kalkos" tinned tube wiring system. This includes a number of new fittings for extending the application of the system, and some special tools for simplifying the installation work. Full instructions for erecting the conduit and fittings are given on a separate leaflet.

MECHANICAL STOKERS.—A leaflet is to hand from the Erith's Engineering Co., Ltd. (70 Gracechurch Street, London), describing the advantages of the firm's patent system of automatic control of both fuel and air supply for use in conjunction with the Erith's grateless underfeed stokers. In this system one small engine drives both the draught fan and the valve-gear controlling the supply of fuel. A chart showing the slight effect of a very heavy variation in load, on the steam pressure at a traction generating station fitted with mechanical stokers on this system, is given in the leaflet.

HIGH-SPEED ENGINES.—Messrs. Alley & MacLellan, Ltd. (Sentinel Works, Polmadie, Glasgow), have issued a new catalogue of their "Sentinel Junior" high-speed steam engines of the single-cylinder and tandem-compound types. The special features of these engines are described and illustrated in detail, and general particulars and prices of a number of combined sets, such as electric generating, pumping, and blowing sets are given. Besides price lists of the various sizes and patterns of engines, prices of dynamos, boilers, and piping suitable for use with them are given. A number of special sets, including motor-driven and belt-driven air compressors, and some large compound intercooling steam-driven compressors, are also illustrated. Other manufactures of the firm include steam-driven motor-wagons, steering gear, hoisting machinery, and light draught steamers.

MANCHESTER MUNICIPAL SCHOOL OF TECHNOLOGY.—We have received the calendar of this Institution for the session 1909-10. It contains full particulars of the various courses of instruction for both day and evening students, as well as much general information about the work of the schools, and is fully illustrated. Some particulars as to the nature of the courses at this Institution were given in ELECTRICAL ENGINEERING, August 19th, 1909, page 739.

ARC LAMPS.—We have received a new price list of arc lamps from Messrs. Drake & Gorham, Ltd. (66 Victoria Street, Westminster, S.W.). This gives details and prices of several of the leading makes of arc lamps, including a new enclosed lamp of Messrs. Drake & Gorham's own registered design. Full particulars and illustrations of this lamp are given on another page of this issue. It is said to be especially adapted for hiring-out purposes on account of its immunity from breakdown and its low cost.

SMALL TOOLS.—An illustrated pamphlet is to hand from Messrs. Vickers, Sons & Maxim, Ltd. (32 Victoria Street, S.W.), dealing with the operations connected with the use of the "Vickers" one-lock adjustable reamer, which is described on another page of this issue.

A.-C. AND D.-C. MOTORS.—The Langdon-Davies Motor Co., Ltd. (Southwark Works, Deverell Street, S.E.), have sent us a booklet containing some useful tables of equivalent values of power measured in kilowatts, horse-power, kilogrammetres, &c., and formulæ for determining the sizes of belts and pulleys. A series of tables giving the ranges of output and speed of the various types of A.-C. and D.-C. motors manufactured by this firm is also included.

"TURN-DOWN" LAMPS.—We have received two leaflets from Messrs. Geipel & Lange (Vulcan Works, St. Thomas Street, S.E.), describing this firm's economical turn-down lamp and a new pattern with a cord from 3 to 15 ft. long, attached to a rotary switch in the lamp socket. The first pull turns the lamp on to its full power (8 or 16 c.p.), the next pull reduces it to 1 c.p., and the third pull switches it off. This action can then be repeated. These lamps have carbon filaments, the main filaments taking 4 watts per candle and the auxiliary (1 c.p.) filaments 8 watts. An electrically operated device for automatically demonstrating the action of these lamps is being supplied on loan to the trade.

TRANSFORMERS.—A pamphlet issued by the Lahmeyer Electrical Co., Ltd. (109-111 New Oxford Street, London, W.C.), describes some large single- and three-phase oil-immersed transformers manufactured by this firm. Curves of temperature rise and efficiency are given, as well as a number of illustrations showing various sizes of transformers and their tanks, including some water-cooled oil-immersed transformers. Some details and views of a transformer sub-station installed at a cement works in Switzerland, where the pressure is reduced from 10,000 volts to 500 and 125 volts respectively by two banks of transformers, and views of sub-stations in Germany, are also given. The two three-phase oil-immersed transformers fitted with a patent air-cooling device and supplied to the Ferndale Collieries (ELECTRICAL ENGINEERING, August 6th, 1908, Vol. IV., p. 209) are also mentioned.

CORRESPONDENCE

ELECTRICAL INSTALLATIONS IN COAL MINES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I read with interest the article on the above in your last issue. It is quite time the old regulations were revised. Since the Stanley disaster, something like a panic has existed both amongst masters and men as regards the use of electricity in mines. The amount of machinery standing at the present time, to say nothing of the serious set-back the electrical industry has received since the above regrettable disaster, is enormous.

Of course, the true cause of the Stanley disaster may never be known, but at the same time it must not be forgotten that electricity has been in use in mines for the last twenty years or more, and that, previous to the above-mentioned disaster, no great explosion has been directly attributed to this cause. The fact, also, that in these old installations sparking and arcing were quite common even in dry and dusty places, and the wretched state in which these installations were left, point to the danger of explosion from electrical causes not being so great as is imagined. I have carried out and am still carrying out numerous experiments on the electrical properties of coal dust, and may shortly publish the result.

I earnestly hope that the committee selected to revise the above-mentioned rules will consist only of persons who have had great *practical* experience in the application of electricity to mining, not exactly from a manufacturer's or designer's point of view, but from purely long experience and personal daily contact with the running and upkeep of electrical plant in mines. This is the class of person who, knowing the defects and weaknesses of present-day appliances, is best able to judge of their suitability or help to frame rules for the guidance of others.

In modern installations sufficient thought is not given to details; the class of appliance to be used and the method of installing are as often as not left to the whims and fancies of single persons. I myself have had to constantly fight these down. Clean and definite lines should be laid down for the installation and type of apparatus to be used; in fact, all apparatus should pass a Government inspection before being used in a mine, and should be placed on a list, as is done in the case of the permitted explosives or as the Admiralty do at present.

I think it would be better if electrical inspectors were appointed for each district, instead of only one for the whole of the country as at present. I know from experience it is impossible for the ordinary mines inspector to deal with electrical appliances. You cannot expect a man to be an electrical engineer and a mines inspector at the same time; both are only learned by great practical experience.

In the latter part of your article the question of persons receiving electric shocks in mines is a subject I have made a speciality of, and have devised a simple and effective apparatus whereby it is *impossible* to receive a shock on any cable, motor, or other apparatus, except, of course, by persons wilfully exposing and touching live terminals. This apparatus was briefly mentioned in a Paper read by Mr. Robert Nelson, the Electrical Inspector of Mines. Had such an appliance been in use on the cable at the Cribbwr Fawr Colliery, the accident in question would not have happened.

H. J. FISHER.

Lambton Collieries, Durham.
September 6th, 1909.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—A brief account of the method I adopt for protecting the underground cables and of the earthing

Digitized by Google

arrangement may be of value to some of your readers. The system I have charge of is three-phase, 500 volts, 40 cycles, which is used for haulage, pumping, and lighting. There are two sets of bitumen cables running from the power-house down the shaft in casing to the top mine to cast-iron distribution boxes at pit eye "main intake," and from there by three-core bitumen cables armoured, taped and braided to the motors, &c., which are all situated in the main intake roads.

The cables are run *behind* the bar legs, which is a splendid protection from falls of roof, &c., and suspended by leather suspenders. These cables have been installed nearly six years, and have never been crushed by falls of roof or runs of tubs. At all junction and distribution boxes there is a cast-iron dividing box clamped to the armour on either side, and these are connected to the boxes and across to the opposite dividing box, which makes the earthing continuous right through the whole system. All motors, switches, fuse-boxes, and transformers are earthed to the armouring, which is connected to an earth plate in the main lodge at pit bottom, and also to the pump stocks which run into the canal at pit bank.

There is also on the main switchboard a leakage indicator, which is always in circuit, and readings are taken and booked every hour. I may say that I frequently make a test from the far end of each system which immediately indicates at the power-house. I have also an electrician on duty at each mine during the day, and one during the night, who have to make a daily report on the equipment under their charge. The whole of the installation is inspected once a week either by myself or one of my assistants, and I think that if proper precautions were taken to see that the earthing arrangements were good, and adequate inspection made, there would be very few accidents.

Yours faithfully,

WALTER WINSOROUGH
(Electrical Engineer,
Douglas Bank Colliery Co.)

Wigan, Lancs.
September 6th, 1909.

LOCAL NOTES

ABERDEEN: *Electricity Charges.*—The Electricity Committee have decided to institute a uniform charge of 3¾d. per unit for lighting consumers. An alternative tariff, however, is offered to consumers using more than 5,000 units each half-year, viz., 5½d. per unit for the first hour of maximum demand, and 1½d. per unit afterwards. Public lighting by arc lamps will, in future, be at the rate of 2d. per unit, and the power tariff will be upon a sliding scale from 2½d. to ⅞d. per unit. A flat rate of 1½d. per unit for heating and cooking has also been fixed.

Electrical Engineer's Report.—The report of the City Electrical Engineer, Mr. J. A. Bell, for the year to March 31st, 1909, states that the year has been unique in the experience of the department, being the first since the start of the undertaking that the units generated show a decrease on the preceding year. Due, however, to economies in distribution, &c., the output sold shows a small increase on the year 1907-8. This small increase in output is partly due to the general depression in trade, but is principally the result of the installation of metallic filament lamps by the present consumers; and, whilst more new consumers have been coupled up during the year than the average for the preceding four years, these consumers do not balance the drop in output caused by the change from carbon to metallic filament lamps. It is estimated that there are already on the mains some 25,000 metallic filament lamps. In Mr. Bell's opinion the undertaking will continue to feel the effect of metallic filament lamps for at least two years more; 175 new consumers were added during the year. Before the financial year ended, negotiations were completed with the Directors of the Royal Lunatic Asylum for a supply in place of their private plant, but this consumer is not yet coupled up. Supply to the Admiralty's Wireless Telegraph Station was started on August 19th. Motors representing 408 h.p. have been coupled up during the year. With regard to mains, copper strip culvert alterations have been carried out in Market Street and George Street, and the most costly and troublesome portions of these culverts are now converted. The output for private lighting consumers is 14,024 units, and for power consumers 65,851 units in excess of the previous year. The total number of units sold for the year for all purposes amounts to 5,170,421, being an increase of 66,385 over the preceding year. A fall in the price of coal has brought coal costs down to a normal figure again, viz., 0·3d. per unit sold. The accounts are not yet ready.

Electrical Showroom.—The Corporation have opened a showroom in Union Street, where a stock of electrical cooking and heating apparatus for domestic purposes will be maintained.

ACTON: *Electricity Charges.*—The Electrical Engineer is to report upon a proposal to grant special terms to shopkeepers for electric supply.

AUSTRALIA: *Sydney: Plant Extension.*—The City Council recently invited tenders for a 4,000 kw. generator having a speed of 750 revolutions per minute. Mr. Forbes Mackay, the City Electrical Engineer, recommended the acceptance of a tender of this description. Among the tenders received, however, were one or two for machines running at 1,200 revolutions per minute, the price being about £1,200 less than for the slow speed machine. Mr. Mackay's reason for recommending the latter was on the score of reliability, as he regarded the higher speed machine as in the nature of an experiment. When the matter was considered by the Council, however, there was considerable difference of opinion, and eventually it was decided to call for fresh tenders, apparently on the basis of the higher speed machine, in spite of Mr. Mackay's advice that the Council would be making a great mistake in installing this type.

Electricity Accounts.—The accounts of the Corporation electricity undertaking for the year to December 31st, 1908, show a total revenue of £87,006 compared with £59,742 for the previous year. The total expenditure was £56,784 against £31,898 in 1907, and after meeting interest and capital charges, there is a net profit of £13,112, compared with £15,556 for the preceding year. The sum of £7,344 has been transferred to reserve, and the balance carried forward.

Commonwealth Telephone System.—The Commonwealth Postmaster-General has, says the *Australian Mining Standard*, published some figures showing the provision made in the estimates for transferring the telephone wires underground. The expenditure on telephone cables amounts to £72,947, of which £33,947 will be expended during the financial year, 1910-11. The total for conduits and laying is £36,101, of which £19,935 is deferred. There will thus be a total expenditure of £109,048, of which £53,882 will be held over until the following financial year.

Victoria: Electric Cranes.—The Victorian Railway Department has arranged to equip all the principal goods stations in the city with electric cranes. The first of these, at Ballarat West, has already been put into operation.

BELFAST: *Tramway Centre Poles.*—At the weekly meeting of the Tramways and Electrical Committee on Monday the City Electrical Engineer submitted a report on the proposed shifting of the tramway centre poles at various points, as recommended by the City Police Commissioners. The committee considered the proposals, and instructions were given to have them carried out.

FINCHLEY: *Power Charges.*—A new scale of power charges has been introduced, viz., 2d. per unit for the first ninety hours' use, and 1d. for all units consumed afterwards.

GLASGOW: *Tramway Traffic.*—Since the beginning of the financial year on June 1st, the number of passengers carried upon the municipal tramway system has been 52,086,879, against 52,876,371 during the corresponding period of last year, whilst the receipts have been £213,551 against £217,419.

KINGSTOWN (Dublin): *Tramcar Speeds.*—With reference to the Council's opposition to the proposed application of the Dublin United Tramways Co. to the Board of Trade for the increase in the speed of their "special" tramcars, an effort was made at the last meeting to get the resolution of the Council against this rescinded. The motion, however, was lost by three votes to seven.

LAUNCESTON (Tasmania): *Electric Tramways.*—The final poll upon the question of electric tramways has resulted in a majority of 2,239 votes in favour of the municipality undertaking the work.

RUSSIA: *Moscow: Tramways.*—The British Consul at Moscow, in his annual report, states that the whole of the work of the concession for the electrification of the Moscow tramway system, to be paid for by Moscow city bonds, was virtually in the hands of a British syndicate, which was to have taken over this loan at the very low price of 75. Unfortunately this very valuable concession was allowed to fall through. The requisite funds having been obtained by means of the loan raised in London, nearly all the plant for the electric trams has now been ordered from Germany. Moreover, this contract for the construction of the electric trams was only the first contract the town was then willing to hand over to the British syndicate—there were other things to follow which would have been even bigger.

Digitized by Google

SALFORD: *Tramways Undertaking.*—The Tramways Committee recommend the Council to revert to the old system with regard to workmen's fares, &c., upon the tramways, as the experimental working of the extension of the various stages and the extension of the hours during which daily return tickets are issued, has not been a success. The Committee state that they are largely handicapped by the high price charged by the Electricity Committee for electrical energy. As a matter of fact, they paid less for the energy consumed by their cars running in Manchester and Eccles than they did to their own Electricity Committee, and if they were supplied with energy upon the same terms as the Glasgow Tramways Committee, there would be a saving of £30,000 per annum.

SCOTLAND: *Water Power Scheme.*—An electric lighting installation in which water wheels are made use of has been put into operation upon the estate of the Duke of Atholl at Blair Castle. Mr. W. H. Massey has acted as consulting engineer, and the installation consists of three 60 h.p. Pelton wheels direct coupled to low-tension continuous current dynamos. A feature of the installation is that no accumulators are employed.

SHEFFIELD: *Generating Plant.*—Upon the report of the Chief Electrical Engineer that the 1,000-kw. Vickers, Sons & Maxim generator is satisfactory, the final 10 per cent. retention money is to be paid.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BENTLEY, DONCASTER.—A Local Government Board inquiry was held last week by Mr. E. A. Sandford Fawcett with regard to a loan for carrying out a sewerage scheme for Bentley Colliery Model Village, Rostall, &c. The scheme consists in laying down several miles of cast-iron pipe sewers on concrete bed. The sewage will all be conveyed to a pumping station, the centrifugal pumps being worked by electric motors, all in duplicate. The pumps will be placed in an underground chamber adjacent to the storage tanks. The motors will be automatically started and stopped by floats. Each pump will be capable of delivering 30,000 gallons per hour of sewage at the existing sewage disposal works.

ITALY.—It is stated that a project is on foot for the establishment of an electric power station on the River Simato, capable of producing 10,000 h.p. The opinion is held that the water-power conditions of Sicily will permit of the erection of electric generating stations at various points in the island, which could be linked together. The proposed scheme includes stations at Palermo, Messina, Catania, and Syracuse.

JOHANNESBURG.—The *South African Mining Journal* announces that tenders are to be invited by the Johannesburg Council for generating plant, as follows: Four boilers, each with an evaporation capacity of 14,000 lb. per hour, £9,800; four mechanical stokers, £3,200; economisers, £2,000; one chimney and necessary flues, £2,200; steam, exhaust, and circulating piping, £1,500; two cooling-towers, £2,000; cooling-pond, £750; two feed-pumps and house, £600; one borehole and pump, complete with house, and reboring existing borehole, £700; removing six boilers, steam pipes, &c., £500; engines, about £34,000.

LONDON: *Hackney.*—On May 20th, the Electric Lighting Committee reported upon the probable necessity for providing a new feeder to the Hackney Wick district, at a total cost of £3,000, but expressed the hope that this expenditure might be postponed until next year by means of certain alterations costing only £65. The committee, however, now report that the existing feeder is fully loaded up, and there being certain large prospective consumers, it is necessary to lay new mains without delay. The estimate is as follows:—New one sq. in. c.c. and pilot cable, £2,920; connection to Lee Conservancy road distributor, £360; connection to High Street, Homerton, distributor, £370. The Finance Committee have passed the estimate. Application is to be made to the London County Council for sanction to borrow the £3,650.

RUSSIA.—The Kharkov Municipality propose to raise a loan of £100,000 for electric tramway construction, and a further loan of £50,000 for the building of an electrical generating station.

SHEFFIELD.—Mains are to be extended at an estimated cost of £380.

Miscellaneous

BIRMINGHAM.—Tenders are invited by October 1st for the supply of 67,000 tons of coal for the electric supply department. Particulars from, and tenders to, Mr. R. A. Chattock, the City Electrical Engineer, 14 Dale End, Birmingham.

DUBLIN.—The Lighting Committee of the Corporation invite tenders for 750 single-phase alternating-current meters. Particulars from the City Electrical Engineer, Fleet Street, Dublin, and tenders to the Chairman, Lighting Committee, 3 Cork Hill, Dublin, by Sept. 13th.

HULL.—The contract for the construction of a low-water pier at Hull for the Hull and Barnsley Railway Co. has been let to a London contractor, so far as the constructional work is concerned. It is proposed to instal a number of electric cranes on the new pier.

SERVIA.—The Servian State Railways invite tenders for two electrically driven centrifugal pumps, each capable of pumping 2,000 litres per minute; one centrifugal pump capable of pumping 500 litres per minute; electric cables and five sets of electric signalling apparatus. Tenders by September 14th to Direction des Chemins de Fer de l'Etat Serbe, Belgrade.

SOUTH AFRICA.—It is stated that the installation of underground telephones is likely to be carried out on the Randfontein Estates, as well as upon other mining properties in South Africa.

TURKEY.—Tenders for the installation and working of a telephone system in Constantinople and the surrounding district are invited by the Turkish Legislature by October 14th. The *Board of Trade Journal*, in making this announcement, states that a competent agent on the spot is practically essential in connection with all Turkish Government contracts.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—Rebuilding 102 Hatton Garden for John Jacques & Sons, 53 Hatton Garden, E.C.

N.E.—Additions to Mortuary at Metropolitan Hospital, Kingsland Road, Hackney. Architects, Young & Hall, 17 Southampton Street, W.C.

S.W.—Extension of Wimbledon Technical Institute (£8,310). Builders, Spenser, Santo & Co., 22 Kensington High Street, N.W.

W.—Rebuilding 19-21 Oxford Street. Builders, Rice & Sons, 15 Stockwell Road, S.W.

Shop, showrooms, &c., Duke Street. Builder, Lole & Co., Trafalgar Square, Chelsea, S.W.

Business premises, flats, and houses, corner of Henrietta Street and Wimpole Street. Surveyors, Elliott, Son, & Boyton, 6 Vere Street, W.

Extensive buildings, corner of Rathbone Place and Oxford Street. Builders, Prestige & Co., 149 Grosvenor Road, S.W.

Buildings, Bond Street and Brook Street. Builder, C. F. Kearley, 4 Great Marlborough Street, W.

Electric theatre and tea-rooms in Oxford Street. Architect, Melville S. Ward, 104 Victoria Street, S.W.

PROVINCES.

ALDERSHOT.—Secondary school (£12,000). Architects, Kingham & Kinghams, Grosvenor Road, Aldershot.

BANBURY.—Council school, Grimsbury (£6,098). Architects, Talbot, Brown & Fisher, Wellingborough. Builder, T. Higgs, Northampton.

BOLTON.—Library, Great Lever. Architects, Bradshaw & Gass, Bolton. Builders, J. Cocker, Walkden.

BOOTLE.—Institute. Architects, Shepherd & Bower, Victoria Street, Liverpool.

CHELTENHAM.—Extensions, ladies' college. Architect, E. Waller, College Green, Gloucester.

EDINBURGH.—Mills for Hill, Craig & Co., paper manufacturers, Balerno.

GOVAN, N.B.—Skating rink. Architect, G. A. Boswell, 53 Bothwell Street, Glasgow.

HINDLEY.—Grammar school (£12,000). Architect, R. Pennington.

LEITH.—School (£10,000). Architect, J. Craig, 85 Duke Street, Leith.

LIVERPOOL.—Skating rink. Architect, G. Dalton, Lord Street, Liverpool.

NEWTON ABBOT.—Secondary school. Architect, P. Morris, 1 Richmond Road, Exeter.

SOUTHEND-ON-SEA.—Roman Catholic Church, Southchurch Road. Father Meenen, Southend-on-Sea.

School (£5,184). Architect, P. Brockbank, County Chambers, Weston Road, Southend-on-Sea. Builder, H. W. Grainger, Southend-on-Sea.

WAKEFIELD.—Home for children. Clerk to the Guardians.

WALLASEY.—House (£1,500). Architect, R. Hulmes, North John Street, Liverpool.

TENDERS RECEIVED AND ACCEPTED

BLACKBURN.—The Council have accepted the tender of the Wigan Coal & Iron Co. for the supply of steam coal to the electricity works.

PLYMOUTH.—The Electrical Engineer has under consideration tenders for additional generating plant at the generating station.

PONTYPRIDD.—Fourteen tenders were received for the supply of a surface-condensing plant, and that of the Worthington Pump Co., Ltd., has been accepted at £1,560. The tender of Messrs. Siemens Bros. & Co., Ltd., has been accepted at £2,894 10s. for a 500-kw. generating set.

SHEFFIELD.—The Sheffield Corporation Tramways Committee have accepted the tender of the Brightside Foundry & Engineering Co., Ltd., for the supply of heating apparatus for the Shoreham Street tramways depôt at £1,012, and that of Messrs. Hodkin & Jones at £2,720 for the reinforced concrete in connection with the construction of the depôt.

WIGAN.—At the meeting of the Corporation last week, the tenders for generating plant recommended for acceptance by the Electricity Committee, and given in our last issue, were duly accepted. It is intended to close the Pemberton power station, and to erect a sub-station there.

COMPANIES' MEETINGS AND REPORTS

DUNDEE, BROUGHTY FERRY & DISTRICT TRAMWAYS CO.—The report for the year to July 31st shows a gross profit of £12,512. The directors recommend a final dividend on the 6 per cent. preference shares; the placing of £600 to renewals fund, and £600 to debenture stock redemption fund, carrying forward £312.

BRITISH THOMSON-HOUSTON CO.—The accounts to March 31st state that during the financial year the company sold twelve turbines aggregating 15,000 kw., and the directors feel confident that the business of the company in steam turbines will be large, due not only to the unrivalled excellence of the company's apparatus, but also to the unique fact that the company can supply either the vertical or the horizontal type, whichever is best suited to each installation. In this connection it is interesting to note that since the end of the year under review the company has sold eighteen turbines, aggregating 18,569 kw. The quantity of electrical equipment for tramway and railway work sold in Great Britain during the year has been very small, but the company has received its fair share of this business. The company has closed several important contracts for switchboards during the year. The company has made further satisfactory progress in the development of metallic filament (tungsten) lamps, and, to meet the increasing demand, is extending its manufacturing facilities. Under the terms of the trust deed securing the issue of the company's debentures, the company had to pay to the trustees on February 28th last the sum of £3,339, to be applied by them in purchasing debentures in the market. Debentures of the par value of £3,500 were purchased prior to March 31st (the end of the year under review), making the total par value of debentures retired to date £7,060. The directors regret that the balance sheet shows a loss of £825 after paying interest on debentures and on loans. They deem it wise, however, to write off certain items, and to that end have carried into the profit and loss account the balance brought forward from last year, viz., £2,466, and the reserve of £15,409. The meeting is on the 14th inst.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £60 5s. to £60 15s. per ton (last week, £60 10s. to £61).

BANKRUPTCY.—H. J. Burdett, electrical engineer and contractor, 16 Regent Street, Rugby, has been adjudicated bankrupt.

AGENCY.—Messrs. Tetley & Co., Falcon Electrical Works, Greengate, Manchester, have appointed Mr. S. Mansel Jones, of 7 and 8 Western Mail Chambers, Cardiff, and 63 Wind Street, Swansea, as their sole representative for Cardiff and South Wales, and have also made arrangements to hold a stock of their standard manufactures at each depot.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The address of the Underground Electric Railways Co. of London, together with the affiliated tube railway companies—viz., the Baker Street & Waterloo; Great Northern, Piccadilly, & Brompton; and the Charing Cross, Euston, & Hampstead have been removed from Hamilton House, Victoria Embankment, E.C., to St. James's Park Station Building, Broadway, Westminster, S.W.

"VICTORIA" TURBO PUMPS.—Messrs. Willans & Robinson have recently taken up the manufacture of centrifugal pumps, for dealing both with high and low lifts, and have at the present time some twelve pumps under construction. A series of tests has recently been completed on one of these pumps, which has shown that the high efficiency estimated by the designer (Jens Orten Boving) has been fully realised in practice. In view of the large number of high-lift sinking pumps imported into this country, there would seem plenty of room for a well-built, reliable British-made pump.

APPOINTMENTS AND PERSONAL NOTES

The Llandilo Urban District Council received 216 applications for the post of electrical engineer. A short list of six candidates has been prepared, and the salary has been fixed at £100 per annum, rising to £130.

Major C. J. Burnaby, R.E., has been appointed Chief Instructor at the School of Electric Lighting, Plymouth.

Mr. G. M. Harris has resigned his post as resident electrical engineer to the Aldrington (Hove) electric lighting undertaking, in consequence of ill-health.

MISCELLANEOUS CITY NOTES

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—It has been decided to make an issue of £500,000 new capital, divided into 200,000 five per cent. cumulative perpetual preference shares of £1 each, at a premium of 1s.; 200,000 five per cent. non-cumulative preferred ordinary shares of £1 each, at a premium of 2s.; and 100,000 deferred ordinary shares of £1 each, at a premium of 3s. These shares are offered to the existing preferred and deferred stockholders in the proportion of two five per cent. cumulative perpetual preference shares, two five per cent. non-cumulative preferred ordinary shares to one deferred ordinary share for every complete £9 of preferred ordinary or deferred ordinary stock held by them.

GLOBE TELEGRAPH & TRUST CO.—A dividend of 2s. per share has been declared upon the ordinary shares.

CANADIAN GENERAL ELECTRIC CO.—A dividend of 1¾ per cent. has been declared upon the ordinary shares for the quarter to September 30th, being at the rate of 7 per cent. per annum.

SAO PAULO TRAMWAY LIGHT & POWER CO.—A quarterly dividend of 2½ per cent. is announced upon the ordinary shares.

Lightning Conductors on Ely Cathedral.—Lightning conductors were first fitted to Ely Cathedral in 1859, but these conductors, formed of short copper tubes screwed together, have recently been tested, and proved to be so defective that it has been found necessary to instal an entirely new system of copper tapes. This comprises two conductors on the western tower, with branches from the flagstaff and four turrets, two from the towers over St. Catherine's chapel and four from the eastern tower, as well as from the nave, choir, transepts, and Lady chapel. The work has been carried out by Messrs. J. W. Gray & Son, of 91 Leadenhall Street, London, E.C., under the direction of Mr. A. Hands.

Honorary Degrees at Birmingham University.—In connection with the recent opening of the new university at Birmingham by their Majesties the King and Queen, the Council of the University has decided to confer, for the first time, a number of honorary degrees. The list, which was prepared by the principal, Sir Oliver Lodge, includes the following names:—Sir William Crookes, F.R.S.; Professor S. P. Thompson, F.R.S.; Sir Alexander B. W. Kennedy, F.R.S.; Sir William Ramsay, F.R.S.; Lord Rayleigh, F.R.S.; Mr. E. Rutherford, F.R.S.; Mr. Maurice Fitzmaurice, Chief Engineer to the London County Council; and Mr. W. N. Atkinson, Inspector of Mines for South Wales.

The Chester Telephone Exchange.—On Saturday last, at 2.30 p.m., the National Telephone Co. transferred the subscribers connected to its Chester Exchange to a Central Battery equipment installed in new premises which have been specially designed in St. John Street, Chester. The new equipment has been manufactured and installed by the Western Electric Co., of North Woolwich, and is of the No. 1 C.B. type, consisting of nine subscribers' positions giving accommodation for 960 lines and three incoming junction positions. The ultimate capacity of the switchboard is 6,000 lines, and the equipment is of similar design to that installed at the company's Altrincham, Birmingham, Midland, Hillhead, and Bromley (Kent) exchanges.

London University Employment Exchange.—We are informed that an Appointments Board has been constituted by the University of London. The terms of reference to the Board are "to assist graduates and students of the University in obtaining appointments, and to co-ordinate and supplement the work done by the schools and institutions of the University with this object," and the object of the Board is to encourage the selection of university men for all posts in the work of which the possession of a university training on scientific methods is an advantage. They wish to assist graduates to find employment, and to assist employers to find, in the university ranks, suitable men for vacancies. Readers knowing of any vacant appointments suitable for university men, should communicate with the Secretary of the Board, so that he may put forward selected candidates.

A NEW DESIGN OF ENCLOSED ARC LAMP

THE accompanying illustrations represent a new design of arc lamp of the single enclosure, shuntless pattern, which is being placed on the market by Messrs. Drake & Gorham, Ltd., of 66 Victoria Street, Westminster, S.W. A common fault with shuntless lamps burning in series is that the feeding takes place unequally, and the arcs get out of balance, and to prevent this effect, this lamp is provided with a device patented by Lewis and known as a "halter." An exterior view of the lamp is given in Fig. 1. The case is dark green, with a polished copper spinning just above the glass reflector, and as it is practically air-tight, the lamp is especially suitable for workshop use and for other dusty positions.

Figs. 2 and 3 show the mechanism of the lamp, which is of the well-known Lewis pattern, in which the regulating lever *C* is controlled by the differential action of the series solenoid *A*, and a weight on the end of an arm attached to the centre of the lever. A dash-pot *B* is provided to ensure smooth regulation. The rod *D* is connected to the clutch holding the upper carbon which is allowed to slip down in the usual way when the arc becomes too long. When two or more of these lamps are running in series the arcs will be of different lengths, and the pressure will not be the same across each, unless all feed at the same time. As this does not happen in practice, and no shunt solenoid is provided to adjust the length of the arc, the arcs would be unequal unless a special device for compelling the lamps to feed simultaneously were not provided. The above-mentioned "halter" is designed for this purpose, and comprises a small iron arm *E*, a vertical extension of which adhers magnetically to the core of the series solenoid when current is flowing. The arm projects cross-wise over the end of the solenoid. When the core has descended to a certain position owing to the lengthening of the arc and the consequent decreased current, its further descent is stopped by the action of the arm which rests on the top of the solenoid. This holds up the mechanism, and the arc lengthens and ultimately breaks with the result that there is no current in the circuit, and all the lamps feed simultaneously. As there is no current, the magnetic adhesion of the arm *E* to the core ceases, and the core is allowed to fall, thereby allowing the clutch to trip and the carbons to feed. This operation takes place at regular intervals, but has no serious effect on the light. A slight flicker only is noticeable, the arcs being very steady in the intervals between these feeding times.

The method of fixing the glass reflector *F* is new, and worthy of notice. This consists in screwing a spun collar *G* up against the frame-plate of the lamp by means of three small screws, as shown in Fig. 3. The globe is readily removed, being held up against the frame-plate by means of the collar *H*, which has projections fitting into metal loops drawn upwards by helical springs *J* in the interior of the case.

These lamps take from 5 to 6 amperes, and give from 60 to 100 burning hours. They can be run singly on 100- and 120-volt circuits, or two in series on 200- to 250-volt circuits, continuous or alternating current. The overall length is 23 in.

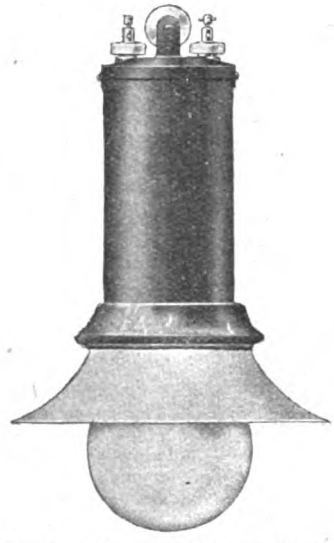

Fig. 1.—External View of Lamp.

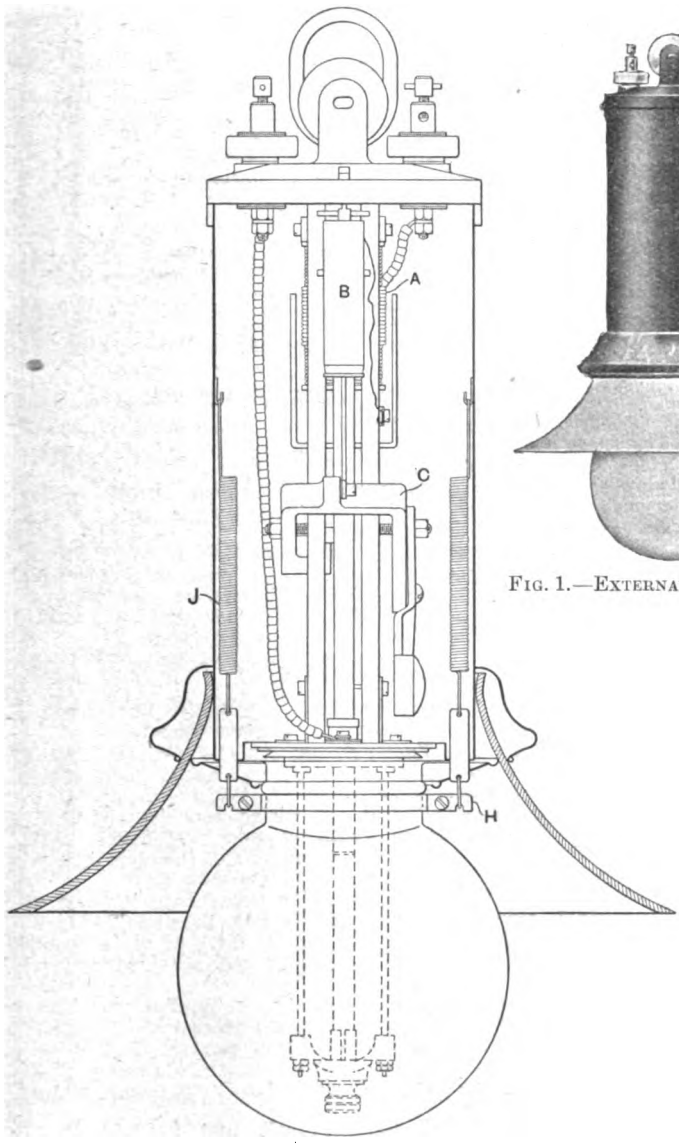

Fig. 2.—View of Mechanism showing Method of Attaching Globe.

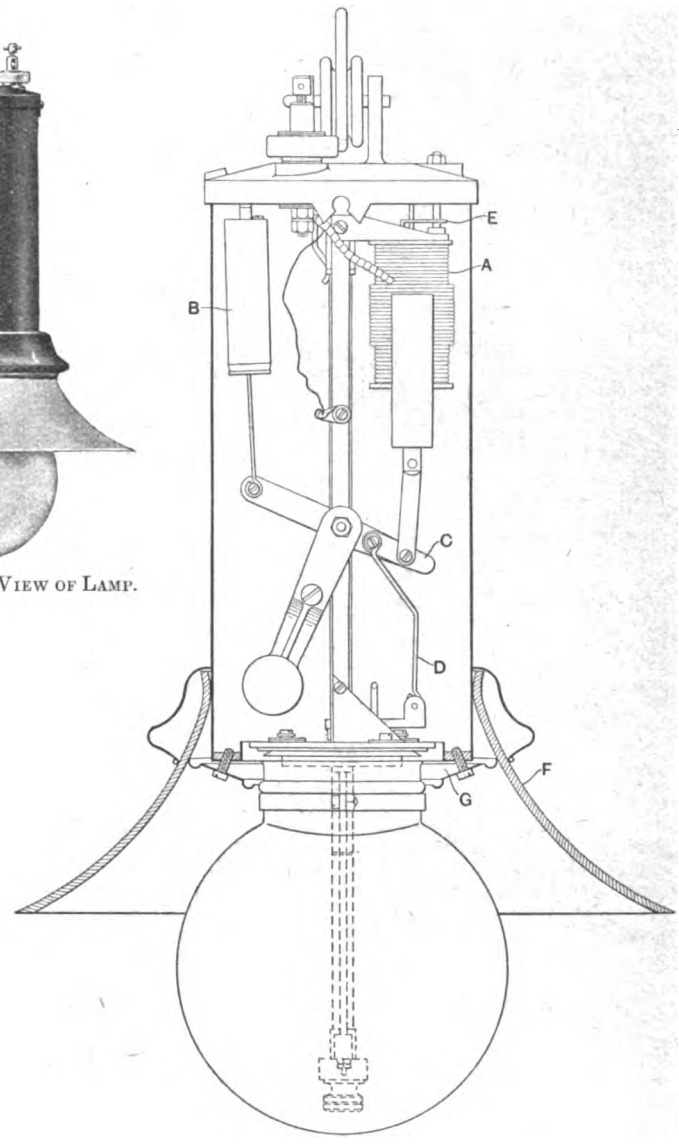

Fig. 3.—View of Mechanism showing Method of Fixing Reflector.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 2nd, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

16,863/08. **Wiring-Conduit Joints.** T. G. HANN. In order to render screw threads at the joints unnecessary, the tee, elbow, or other jointing piece is formed in two longitudinal parts. Grooves are made in the interior of each half near the ends, so that annular recesses are formed when the two halves are put together. The ends of the tubes to be joined are flared outwards, and are placed between the two halves of the jointing piece, so that the flanges fit into the annular recesses. The two parts are then firmly united by screws passing through lugs. Clamping rings may be used for this purpose instead of lugs. Four claims, seven figures.

16,997/08. **Control of Traction Motors.** BRITISH THOMSON-HOUSTON Co. and F. W. CARTER. Compound-wound traction motors, adapted to be run as generators while the vehicle is coasting or reducing its speed so as to return energy to the line, are so controlled that when an overload occurs the motor will be provided with a full series field, so as to bring down the speed, but that the shunt field will be opposed by a full series field when the motor begins to generate. This is accomplished by arranging reverse-current and overload relays in the exciting circuit of a contactor, which, when closed, completes a diverter circuit about the series field of the motor. During normal operation, this contactor is closed and the series field shunted. Should an overload occur, or the motor begin to generate, the contactor is operated and the diverter circuit broken. Two claims, three figures.

17,211/08. **Magnetic Track Brakes.** C. SHEARS. In an improved construction of magnetic track brake shoes for tramways, the side-plates are formed separately from the connecting cores carrying the energising coils. The cores have projections which fit into recesses in the side-plates, the latter being held together by bolts which do not pass through the cores. Brass sheaths surround the coils, and the ends of these sheaths fit into annular grooves in the side-plates. The connections are made in grooves in the side-plates, which are afterwards filled with pitch to prevent the access of moisture. Three claims, ten figures.

1,509/09. **Protective Device for A.-C. Generators.** SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke-Ges.*). This is a device to prevent overloading in the event of a temporary short-circuit without cutting off the supply to the circuit, and is especially designed for use with generators working with automatic voltage regulators, which tend to increase the current on short-circuit. It comprises two relays, operated by shunt and series coils respectively, which cause a resistance to be switched into the field circuit of the exciter directly an excess current or voltage obtains. The resistance is kept in circuit until the normal conditions are restored, when it is automatically cut out again. Two claims, one figure.

Amendments to Specifications

23,899/04. **Manufacture of Tungsten Filaments.** A. JUST and F. HANAMAN. Leave has been granted to make certain amendments to the specification of this important patent. The matter is dealt with at length elsewhere in this issue.

20,223/07. **Manufacture of Tungsten Filaments.** THE "Z" ELECTRIC LAMP SYNDICATE, LTD., wish to amend this specification, which was abstracted in ELECTRICAL ENGINEERING, December 10th, 1908, Vol. IV., page 772. The amendment consists in deleting the statement that a "hydrogenous compound of tungsten" is formed during the process. It may be remembered that the grant of this patent was at first opposed, but that the opposition was withdrawn last month (as stated in our issue of August 19th last), and the patent granted.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, etc.: GRAY [Conductors] 17,283/08; PHILLIPS and BACON [Insulating composition] 17,340/08.

Electric Ignition: BIRD and THOMSON-BENNET, LTD. [Ignition apparatus for engines] 26,894/08; WATTLES [Magneto device] 28,343/08; MARKS (*Chicago Coil Co.*) [Induction coils] 318/09.

Electrometallurgy and Electrochemistry: BIANCO [Electrolytic galvanising process] 15,031/08; BRACHMANN [Electroplating] 23,193/08; CONNOR, STUBBS, and ELECTROLYTIC ALKALI Co. [Electrodes] 23,930/08; GERBING [Electroplating non-conducting articles] 24,139/08; DE MARTIS [Primary cells] 26,285/08.

Heating and Cooking: PHEYSEY [Heating apparatus] 17,687/08.

Incandescent Lamps: SCHÄFFER [Manufacture of flat metal filaments] 28,554/08.

Instruments and Meters: THORPE [Electrolytic meters] 865/08; SCHNEIDER [Pivoting axles of instruments] 25,530/08; SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke-Ges.*) [Bearings] 16,538/09.

Storage Batteries: MONTGOMERY, YOUNG, HELLYER, and BAKER, 9,692/09.

Switchgear, Fuses, and Fittings: COX [Switches] 17,315/08; WOODS [Electroliers] 19,183/08; BIRCHALL [Lamp-holders] 1,673/09.

Telephony and Telegraphy: MARCONI, and MARCONI'S WIRELESS TELEGRAPH Co. [Apparatus for wireless telegraphy] 17,505/08; HARPER [Windings of telephone induction coils] 23,739/08; CLARKE [Telephone instruments] 26,315/08; DEGENER-BÖNING [Wireless apparatus for indicating positions of ships] 2,845/09.

Traction: FIRTH and LEAKE [Relays for block-signalling] 10,509/08; WILLIAMS [Locking points or switches] 17,343/08; GRESHAM [Vacuum brake] 17,658/08; SCHWARZ and GRIESS [Tramway points and switches] 1,043/09; BROOKE [Vacuum brake control] 1,376/09; SIEMENS BROS. & Co. (*Siemens & Halske A.-G.*) [Signalling apparatus] 14,240/09.

Miscellaneous: PIERINI [Synchronous working of cinematograph and gramophones] 10,396/08; LOEBL and BRITISH EVER READY ELECTRICAL Co. [Electric clocks] 785/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electrochemistry: BUNET and BADIN [Electrical production of nitrates] 16,224/09.

Switchgear: VIRY [Control of mechanism from a distance] 18,624/09.

Opposition to Grant of Patents

26,588/08. **Wave-Length Measurer.** MARCONI'S WIRELESS TELEGRAPH Co., LTD., and H. J. ROUND. A patent has been granted on this application in spite of opposition. It is for a wave-length measurer comprising a resonating circuit, and a crystal with asymmetrical electrical properties connected across the condenser in series with a telephone.

27,470/08. **Loading Coils for Submarine Cables.** W. S. SMITH and W. P. GRANVILLE. Opposition to the grant of a patent on this application has been entered by Messrs. Siemens Bros. & Co. Further particulars will be found in an article on another page of this issue.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Mercury-vapour rectifiers and lamps] 10,214-5/05.

Distribution Systems, &c.: O. IMRAY (*Safety Conduit Co., U.S.A.*) [Preparation of inside of wiring conduit] 11,500/98; GOESSMANN [Manufacture of insulating paper] 10,535/01; L. M. WATERHOUSE and SIMPLEX STEEL CONDUIT Co. [Conduit fittings] 11,377/02.

Dynamos, &c.: L. SCHÜLER and FERRANTI, LTD. [Control of single-phase repulsion motors] 11,299/03; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [High-frequency alternator] 10,320/05 and [Pump with self-contained motors] 10,554/05.

Electric Ignition: C. J. MONTGOMERY and W. PRESCOTT [Contact ring] 10,147/05; W. ROOS [Magneto generator] 10,599/05.

Electrochemistry: M. OTTO [Ozonising apparatus] 11,128-9/03.

Meters: BRITISH THOMSON-HOUSTON Co. (*Allgemeine Elektricitäts Ges.*) [Switch mechanism for prepayment meter] 11,532/04.

Switchgear, &c.: S. W. MARTYN [Wall plug] 11,309/04; F. A. GRIFFIN [Switch] 10,265/05; L. SUNDERLAND and G. C. PILLINGER [Lamp-holders] 10,288/05; W. T. HENLEY'S TELEGRAPH WORKS Co., and W. H. NICHOLS [Fuse boxes] 10,296/05; L. K. JOB [Thermal switches for signs] 10,609-10/05.

Telephony and Telegraphy: J. B. BIRNBAUM and F. G. BELL [Fire alarm apparatus for use on central battery telephone systems] 10,400/05; L. ZEHNDER [Wireless telegraphy] 10,601/05.

Traction: J. DEVONSHIRE (*W. B. Potter*) [Controller with braking contacts] 10,817/96; SIEMENS BROS. & Co., and L. M. G. FERREIRA [Signalling apparatus] 11,315/03; R. P. SKINNER [Signalling] 11,481/04; W. P. THOMPSON (*McPhee Automatic Signalling Co., Canada*) [Stopping trains by track circuits] 10,194/05; G. T. TRINDER and T. D. CRAMB [Guard-board standard for third rail protection] 10,341/05; J. S. DRONSFIELD and C. J. HUNTLEY [Trolley pole] 10,446/05; V. JORSCH, J. PETRIK, and R. BUTTA [Electrically worked points, and trolley wheel contacts for auxiliary wire] 10,581/05.

Miscellaneous: F. R. BALDOCK [Fire and burglar alarm systems] 10,130/05; P. M. JUSTICE (*Otis Elevator Co., U.S.A.*) [Lift gear] 10,270/05

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

On Tuesday the widened Blackfriars Bridge was opened by the Lord Mayor, and there is now a tramway service across the bridge. Electric power was employed exclusively to work the cranes, compressors, and hoists used in connection with the work of widening. The subways at the north end are not yet complete. The construction of these necessitated the diversion of the existing L.C.C. pipe-subway and the relaying of a large number of gas- and water-pipes, besides numerous cables. The Post Office have constructed three new lines of ducts, and have lengthened and diverted 105 telephone and telegraph cables. The National Telephone Co. have likewise been obliged to move and lengthen a number of cables, while two supply companies have relaid a number of mains. All this work was done without interrupting the supply or disturbing the telephone circuits. (Pages 809 and 821.)

Lord Rosebery's speech at Glasgow on Friday was transmitted by electrophone and trunk lines to the *Evening News* office in London, where it was transcribed by reporters, and the entire speech was published in that newspaper within a few minutes of its conclusion. We describe the arrangements made for this, and publish a photograph of the "electrophone" room at the *Evening News* office during the reception of the speech. (Page 811.)

A 500-ampere-hour battery of 245 cells is used with a crane equipment at Southampton, supplied by two 150-h.p. gas-engine sets. With a line-load varying between 0 and 800 amperes, the generator load is maintained practically constant at 180 amperes. (Page 812.)

A Paper read by J. L. Woodbridge before the American Institute of Electrical Engineers in June last described the 8,500 ampere-hour battery plant for regulating the alternating-current load at the works of the Indiana Steel Co., Gary. Two split-pole rotary converters are used for the interchange of energy between the A.-C. and the D.-C. circuits, and these are regulated by means of an exciter controlled by current transformers in the main A.-C. circuit. This enables a load varying between 5,000 and 9,000 kw. to be dealt

Digitized by Google

with by generators whose maximum load is 6,500 kw. only, and permits the shutting-down of one 2,000-kw. gas-engine set. (Page 813.)

A LETTER from Mr. W. C. Mountain, dealing with our article on September 2nd, welcomes the coming revision of the Home Office special rules for the use of electricity in mines, and points out certain ambiguities in the existing rules. The bulk of the accidents that have arisen, he says, have been in the use of coal-cutting machines.—Mr. H. Jenkins, writing on the same subject, mentions cases in which men have received shocks from rails underground as one of the reasons for proper earthing. He thinks colliery managers should pay better salaries to men in charge of the electrical plant, and thus have better men, and he takes the view that more legislation in connection with electrical apparatus is not needed.—Mr. J. Frost gives a list of some of the chief points to be observed in laying cables in mines, evidently dictated by practical experience. In the case of joint-boxes, he suggests the use of double glands, one to surround the cable itself and one to clamp down the armouring.—Mr. C. W. Salt (Assistant Electrical Engineer, Bradford) sends us some interesting photographs of faults that have occurred through the neglect of bonding street cables, and describes the methods of bonding now employed at Bradford.—Mr. E. J. Fox and Mr. Batley have written us on the question of higher speeds for turbine sets in generating stations. (Pages 815 to 817.)

IN reply to a question in the House of Commons, Mr. Churchill stated that the time had not come to make the installation of wireless apparatus compulsory on board ship. Mr. Henniker Heaton will introduce a motion urging the abolition of political frontiers for wireless communications, and the consideration of the Marconi Co.'s offer to establish a penny-per-word wireless system between the United Kingdom and Italy. A large scale experimental station has been installed at the Armstrong College, Newcastle-on-Tyne. The Uruguay Government intends to erect three wireless stations, and the Chilian Government is also considering the establishment of stations at Valparaiso and elsewhere. On Saturday last a demonstration of a new automatic transmitter for wireless telegraphy designed by Dr. Poulson was given at Cullercoats; a speed of over 100 words per minute was obtained. (Page 818.)

MR. T. MATHER, F.R.S., will take up his appointment as Professor of Electrical Engineering at the Central Technical College at the commencement of the forthcoming session on October 5th. Mr. G. W. O. Howe has been appointed Assistant Professor. (Page 818.)

THE second report of the Royal Commission on Mines, which is just issued, recommends the use of electricity in shot-firing. Miss-fires with electric detonators are constantly diminishing, and hang-fires are rare; a five or ten minutes' interval is recommended before a miss-shot is approached in the case of electric exploders. The report also deals with the locking and re-ignition of safety lamps, and in an appendix a strong opinion is expressed that the person in charge of electric power plant should have a certificate of qualification. (Page 819.)

PROF. RÒITI has issued his report on the International Conference on electrical units and standards, held last October in London, to the Italian Minister of Commerce. He speaks sarcastically about the two zeros added to the figures defining the standard values, and thinks that it is not necessary to put them into the law. In his opinion, the absolute system should be mentioned, and the amount of tolerance permissible in standards supposed to conform with the decision of the Conference should be defined. (Page 821.)

A REPORT has been drawn up by Prof. L. Herdt on the causes of the electrolysis of water-mains and telephone cables in Winnipeg, which has resulted in considerable trouble. The electrolysis is attributed to stray currents from the Winnipeg electric railway system consequent upon poor bonding of the rails, insufficient section of the return feeders, and the fact that the whole of the current is taken from a single sub-station fed from a large water-power station. Prof. Herdt recommends the immediate rebonding of the rails and the construction of three new sub-stations, besides an increase in the section of one of the return feeders. Frequent inspection of the track returns is also insisted on. (Page 821.)

THE Local Government Board have sanctioned a loan applied for by the Bath Corporation last June chiefly on account of expenditure already made on mains.—An extensive scheme of suburban railway electrification is being taken in hand in Paris in connection with the lines from the St. Lazare Station.—A tramcar got out of control while descending a steep hill in Pudsey last week. One or two passengers were slightly injured.—The electricity accounts of the South Shields Corporation record a final surplus of £1,209.—The Willesden Urban District Council will oppose the L.C.C. tramway scheme from the Marble Arch to Cricklewood unless certain road widenings are carried out.—Street lighting by metal filament lamps and arc lamps is to be adopted in Worcester. (Page 822.)

IT has been decided to instal a 50-b.h.p. Diesel engine at Bray.—Tenders for a considerable amount of telephone apparatus are required in Australia.—A tender for the supply of Beck flame lamps for street lighting in Worthing has been accepted. (Page 822.)

THE report of the Yorkshire Electric Power Co. records a net profit of £1,069. There has been a steady increase in supply, and further generating plant will shortly be required. (Page 824.)

MESSRS. WILLANS & ROBINSON are placing on the market a steam turbine of the impulse type for cases in which a speed of 3,000 r.p.m. is admissible. (Page 824.)

A NUMBER of improvements have been made in the Jandus enclosed flame arc lamp. Both carbons now contain chemicals, and the rocking lever is mounted on ball-bearings. A new pattern of automatic cut-out with a self-replacing mechanism has been introduced. (Page 824.)

AMONG the specifications published by the Patent Office on Thursday last was one by W. B. Thorpe, describing several improvements in electrolytic meters. A gas-tight joint between the mercury column and the tube is effected by fusing platinum rings into the glass, and means are provided to prevent oxidation and the evolution of gas at the surface of the mercury column. R. K. Gray has covered a method of protecting the wires of compound conductors by coating all the elements of the conductor with the same metal. G. Marconi has protected a form of transmitter for wireless telegraphy, consisting of two oppositely rotating discs with copper pegs between which the discharge takes place. A process of flattening metal filaments is described in a specification by W. Schäffer, and another by T. Birchall relates to incandescent lamp-holders in which spring contact plungers are dispensed with, the insulating block containing the contacts being pressed downwards by a spiral spring in the cap of the holder. A patent by G. H. Davis for electrically-operated pianos, and another by C. Hoepfner for soluble anodes in electrolytic cells for the deposition of zinc and other metals, expire during the current week. A large number of interesting patents have become void owing to the non-payment of renewal fees. (Page 826.)

BLACKFRIARS BRIDGE WIDENING AND SUBWAYS

On Tuesday last the widened Blackfriars Bridge was formally declared open by the Lord Mayor of London. Besides giving a larger accommodation for the ordinary vehicular traffic, the widening enables the London County Council to complete the loop of their tramway system by connecting up the Blackfriars end of the Victoria Embankment section with the south system across the bridge.

Each pier and abutment of the bridge has been extended 30 ft. on the west side, making the total width of the bridge between the parapets 105 ft. This work has occupied just over 2½ years, and the total cost of the work has been £210,000, which includes the laying of the tramway tracks. The ordinary L.C.C. tramway construction on the conduit system has been adopted, as in the case of the lines across Westminster Bridge (see Electrical Engineering, Jan. 3rd, 1907, Vol. I., page 11). The tracks have been laid on the west side of the bridge, adjacent to the new footway.

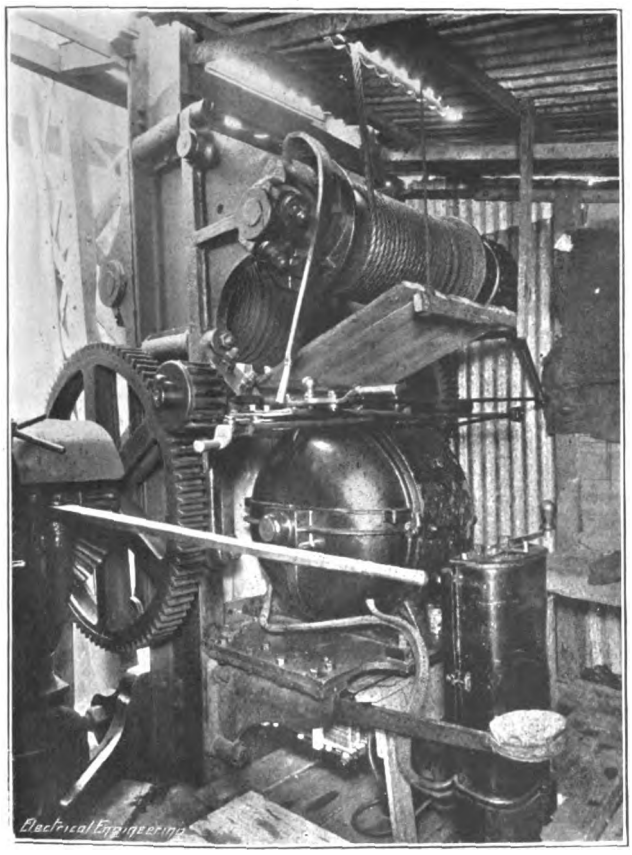

Fig. 1.—40-h.p. Motor and Gear of 15-ton Crane.

On the north side of the bridge the minimum radius of curvature of the track is 70 ft.

The following particulars of the electrical equipment of the cranes, compressors, &c., used in connection with the widening are of interest. Electric power was chosen in preference to steam power to obviate nuisance from smoke and noise. Power was obtained from the City of London Electric Lighting Co., some of whose mains run across the bridge. Some fourteen motors, ranging from 10 to 40 h.p. and taking about 265 kw. in all, were installed; and for the lighting of the works a large number of incandescent and arc lamps were used. Two 15-ton cranes for dealing with the heavy masonry loads, two 10-ton fixed derrick cranes for unloading material from the barges, and one 7-ton crane, were erected. The first of these were equipped with motors of 40 b.h.p., one of which is illustrated in Fig. 1. The others were supplied with motors of 30 b.h.p. For raising the buckets from the working chambers in the caissons, winding gears driven by 10-b.h.p. motors were employed, and the two compressors for maintaining the air-pressure in the working chambers of the caissons were also electrically driven. These were situated in a separate house at the north end of the bridge, and were driven by 35-h.p. motors. One of these is illustrated in Fig. 2. The maximum air-pressure required was 25 lbs. per sq. in. above the atmosphere. Besides the above, there were two more 30-h.p. motors and two 16-h.p. motors employed on the works.

The contract for the widening of the bridge was let to Sir William Arrol & Co., Ltd., of Glasgow, and Messrs. Dick, Kerr & Co., Ltd., carried out the construction of the tramway track. The work was originally in the hands of the late Sir Benjamin Baker. For some months, however, Mr. Basil Mott has been responsible for the work. The resident engineer is Mr. D. Anderson, through whose courtesy we were enabled to obtain the information embodied in this article.

The passenger subways between the Embankment and the footway at the corner of New Bridge Street,

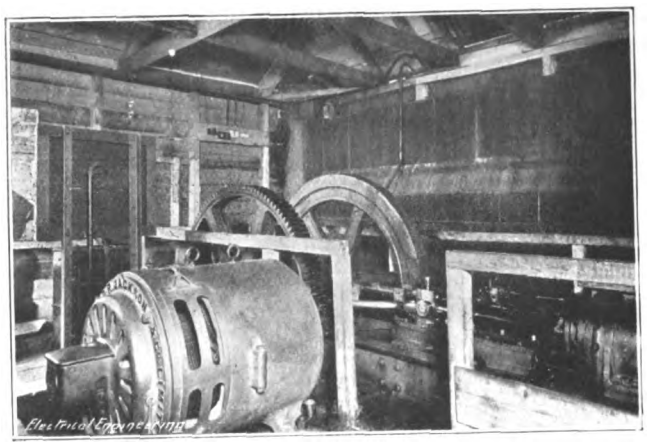

Fig. 2.—Air Compressor and 35-h.p. Motor.

and between Blackfriars Station and the footway on the opposite side of the road, respectively, are not yet open to the public, but are nearly completed. There is an L.C.C. pipe-subway, which runs along the Embankment across the area in question and down Queen Victoria Street. This was found to be in the way of the projected passenger subways in two places, and, as shown in the plan, Fig. 3, the pipe-subway had to be sunk under the passenger subway at these points, and at one point was also diverted sideways. This necessitated the reconstruction of a large amount of pipe-work, and the diversion of a number of power, lighting, and telephone cables which are run through the subway in question. The pipe-subway is 9 ft. wide by 7½ ft. high, and at the points where it has been reconstructed steps lead up and down between the upper and lower levels. A large number of water-pipes, including an hydraulic main and a number of very large gas-pipes, had to be diverted, and also cables belonging to four different authorities, viz., the General Post Office, the National Telephone Co., the Charing Cross, West End & City Electricity Supply Co., and the City of London Electric Lighting Co. These had to be lengthened also, owing to the dip of the pipe-subway. The plan on page 810 shows approximately the position of the cables.

The magnitude of this work may be estimated by the fact that, of the total amount of £30,000 allotted

Digitized by Google

to the passenger subways, only £10,000 goes to the contractors for the actual constructional work (Messrs. Perry & Co., Ltd., of Bow), the remaining £20,000 being needed to cover the cost of the diversion of the various pipes and cables. This latter work was in each case done by the authorities owning the pipes or cables, the cost of the work being refunded by the City Corporation out of the above-mentioned sum.

The largest amount of work in connection with the diversion of cables was done by the General Post Office, who have altered the course of no less than 105 dry-core cables of 35 different types, including eight 1,212-wire cables, each of 2·75 in. diameter. In many cases the pieces of cable in stock were not sufficiently long to extend the full length of the new sections from *K* to *E*, and three joints had to be made. In the first place, a 90-duct line, 20 ft. below the street level, and passing underneath the passenger subway, was constructed between the manholes *C* and *B*. This contains 55 cables at present. A smaller line of ducts running westwards from *C* contains 42 cables, and has not been touched; but the 30-duct line running

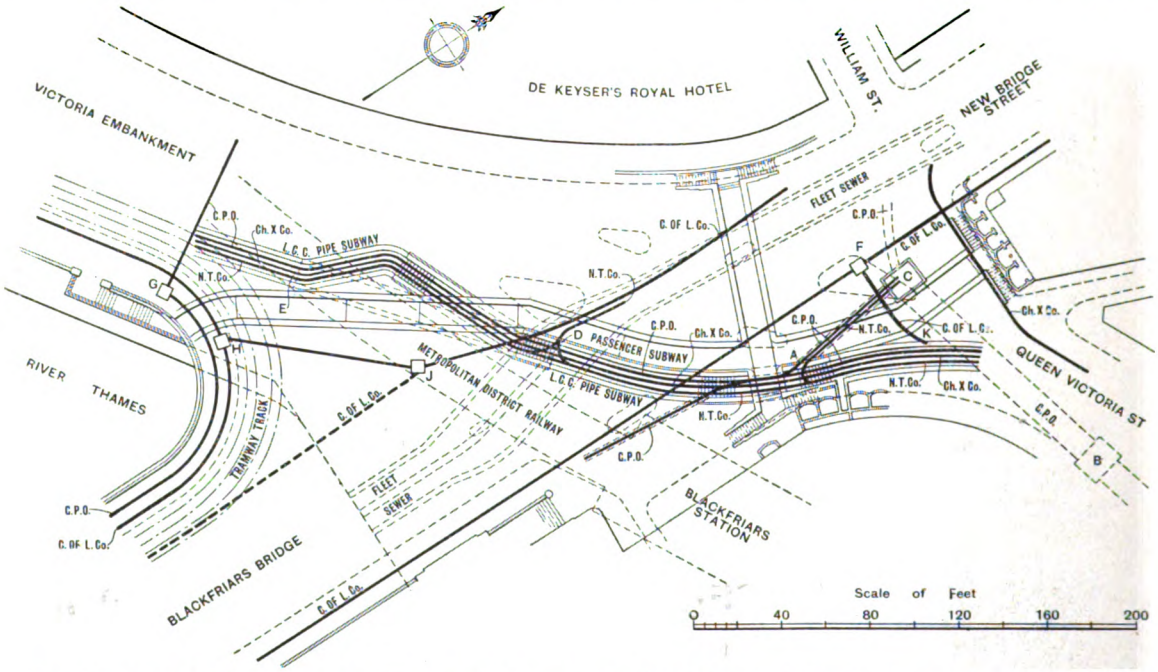

FIG. 3.—PLAN OF PASSENGER AND PIPE SUBWAYS SHOWING APPROXIMATE POSITION OF THE CABLES WHICH HAVE BEEN DIVERTED.

from *C* to the L.C.C. pipe-subway, and containing 22 Post Office cables and two National Telephone Co. cables, has been reconstructed at a lower level, so as to run below the passenger subway. From this point onwards there are 34 Post Office cables of various sizes running along the pipe-subway. Besides these last, a large new trunk cable running to Uxbridge has been drawn recently into the pipe-subway. It has a diameter of 3·5 inches. The shelves erected in the pipe-subway by the Post Office are constructed as follows:—A piece of iron of channel section, bent to the curvature of the subway, is fixed to the wall, and has a series of bolts along its length, over which are hooked iron arms. New shelves can easily be added, and the old ones can be altered in height by hooking the arms over different bolts. Lengths of angle-iron are bolted to the arms at each extremity, and short pieces of wooden board are placed crosswise between the angle-iron pieces to support the cables. In some places there are as many as seven such shelves, and where the pipe-subway dips under the passenger subway the shelves have been curved, and prevent sharp bends in the cable. Some small gutta-percha cables of the Exchange Telegraph Co. are supported on insulators attached to the channel-iron supports of the Post Office shelves.

The line of ducts indicated on the plan under the new footway on the west side of the bridge contains the power cables which come from the new power station of the Post Office on the opposite side of the bridge. This power station is not yet quite completed. From the manhole *G* these cables run under the tramlines across the Embankment.

Eighteen large lead-covered cables belonging to the National Telephone Co. run along the pipe-subway in Queen Victoria Street. These consist of the following:—One 800-pair cable, two 306-pair, four 204-pair, two 217-pair, two 150-pair, five 50-pair, one 25-pair, and one 22-pair. The last two and a few of the 50-pair cables are paraffin-insulated, but all the others are dry-core cables. Some of these come from the Bank exchange, others come from the south of London *via* Budge Row, and another group comes from Cornhill. As shown on the plan, two of the 18 cables branch off into two of the 30 new ducts belonging to the General Post Office, which open into the reconstructed part of the pipe-subway at *A*; the remaining 16 cables are brought up the steps and along the short section of the old pipe-subway to *D*, where two branch off into ducts just before the second dip is reached. At this point, also, is a distributing box, into which is led one of the 204-pair cables, and from which a number of smaller distributing cables are taken. Another cable belonging to the National Telephone Co., and coming from the opposite end of the subway, also enters a duct at this point, and the group of 13 cables is carried on without any further branches to the point *E*, and onwards along the original subway under the Embankment.

The method adopted by the National Telephone Co. of supporting their cables in the subway consists in arranging T-iron brackets at distances of from 3 ft. to 4 ft. apart along the wall of the subway, and buried to from 10 in. to 12 in. into the brickwork. Wooden boards, previously treated to make them fireproof, are supported longitudinally between these brackets, the ends being notched to prevent them from shifting. The cables are simply laid upon these boards. There are two such shelves along the greater part of the subway, but in the new section, between the points *D*

Digitized by Google

and *E*, these are run into one, and in this case the long brackets are further supported at the ends from the roof of the subway.

The following method was adopted in connecting up the new sections. The new parts of the subway were constructed without interfering with the cables, and the new lengths of cable, extending in most cases from the point *K* to the point *E*, were drawn in. The two ends of these new lengths, and the points on the old cables where the joints were to be made, were stripped of their lead covering, and two jointers were set to work simultaneously. A special arrangement of induction coil and condensers giving a very low note in the telephone was employed to identify the separate wires. This was necessary, as, most of the cables being junction cables, there were always signals passing through, which could not have been easily distinguished from the testing signals had an ordinary set been used. The jointer at one end connected one terminal of the induction coil to one wire, and the other to the sheath, and the other jointer connected one terminal of his receiving set to the sheath, and with the other terminal pricked round the wires at his end of the cable. A faint tone was heard on touching each wire, owing to induction, and this notified the receiving jointer that the test connections were made; but when the proper wire was touched, a strong sound was heard in the telephone. After the second wire of the pair had been found in a similar way, the joints made, and all the other pairs dealt with as well, the intermediate section of the old cable was cut away, and the joints taped up and given a wiped lead covering. The whole process of inserting the new length of cable was thus accomplished without interfering with the service. To prevent the cables from absorbing much moisture, it was necessary to complete the work in as short a time as possible, and each cable was worked at day and night after it was once opened until completed. When sealed up, each cable was dried out by desiccated air from the exchange end in the usual manner.

Four extra-high-tension three-phase three-core cables of the Charing Cross, West End & City Electricity Supply Co., each capable of transmitting 2,000 kw. at 10,000 volts, and laid in quarter-inch steel troughing filled up with an insulating compound, are now being diverted. This troughing was buried about 5 ft. below the surface, and ran from New Bridge Street to Queen Victoria Street, as shown on our plan. It is now being diverted and raised so as to pass above the passenger subway. This work is being done without interrupting the supply, as at certain times one cable can be spared at a time and cut off from the system. The steel troughing of these E.H.T. cables is bonded, and the conductivity is so high that with 500 volts, 200 amperes were passed through a length of nine miles. Besides these cables, there are four 100-volt cables and four 1,000-volt cables, all of which run through the pipe-subway, as denoted in the plan. These are placed in cast-iron troughing filled up with sand.

The remaining authority, which was obliged to divert some of its cables, was the City of London Electric Lighting Co. In the first place, about twenty-six cables crossing the bridge on the west side were set back some 30 ft. from their position, shown dotted in our plan, to a position (shown by a full line) under the new footway, and new mains were put in between the manholes *H* and *J*. From *J*, the company's mains run along over the subways to New Bridge Street. As will be seen, there is another line of mains comprising some 27 high-tension cables crossing the bridge on the east side, and running right across to New Bridge Street. To avoid the necessity of moving these, the passenger subway was sunk somewhat below the projected level at this part. From the manhole *F*, however, close to the Post Office manhole *C*, fifteen 420-volt cables were raised, so as to pass above the passenger subway, and enter the pipe-subway at a higher point than previously. These are continuous-current concentric (0·5 sq. in.) cables, and supply current for power, and both public and private lighting. All the City of London Co.'s cables are drawn into wrought-iron pipes. The diversion of all these cables was effected without interfering with the supply. Many of the cables supply power at night for driving the printing presses of the large newspapers in the Fleet Street district.

REPORTING LORD ROSEBERY'S SPEECH BY ELECTROPHONE

WITH the help of the electrophone, the two-hours' speech on the Budget which Lord Rosebery delivered in Glasgow last Friday was listened to in London, and a report appeared in the London *Evening News* within a few minutes of the conclusion of the speech in Glasgow. Some of our readers may remember a similar feat performed in connection with the famous speech of Mr. Joseph Chamberlain in Birmingham on November 4th, 1903, but the distance in the present case was much greater (Glasgow being 400 miles from London). Moreover, in the Birmingham case, the speech was delivered between 8 and 10 p.m., while Lord Rosebery's was in the middle of the afternoon, when the trunk telephone traffic is at its busiest. Somewhat similar arrangements had also been made in the case of a speech by Mr. Balfour at Sheffield, about a month previously to Mr. Chamberlain's speech.

Round the rostrum in the Glasgow City Hall a number of electrophone microphones were placed. They were not fixed to the rostrum itself, but were placed around it and protected from vibration by springs, so that they should not be affected by any movement on the rostrum or platform. The type of microphone employed for the transmission in 1903 was a carbon granule "two-cell" transmitter. In this pattern the carbon back-block is split into two halves, with a strip of cotton-wool between, so that the current passes from one half of the back-block through the granules to the carbon diaphragm and back to the second half of the back-block. At Birmingham and Sheffield two transmitters of this type were used, and four others erected as spares in case of accident. We understand that the microphones used last week in Glasgow differed in some respects from these, but for commercial reasons Mr. H. S. J. Booth, the manager of the Electrophone Co., prefers to withhold technical details as to their construction, or information as to the number in use.

From the Glasgow City Hall special wires connected the transmitters to the National Telephone Co.'s exchange, and thence the ordinary trunk junction lines led to the Post Office exchange, at which connection was made to the Glasgow-London trunk line. There are four trunk lines from London to Glasgow, running entirely overhead except in London itself and in some of the larger towns through which they pass, and two of these were made use of. They were connected through the Post Office trunk exchange in Carter Lane, E.C., and the Holborn exchange of the National Telephone Co., to Carmelite House (the offices of the *Evening News*), where there was a special switchboard erected and in charge of a member of the National Telephone Co.'s engineering staff. At this switchboard one line was connected to one of the *Evening News* offices, and the other to the offices of the Electrophone Co., Ltd., in Gerrard Street. This course was adopted so that in the event of the trunk line allotted to the *Evening News* becoming defective, the second line could be called into requisition. This necessity did not arise, however, and the second line was used all the time for the purposes of

Digitized by Google

a private demonstration given by the Electrophone Co.

The photograph of the reporters at work at Carmelite House, given below, has been kindly lent us by Mr. Booth. Twelve shorthand reporters sat with the electrophone receivers to their ears, and each reported for two minutes only at a time. After the two minutes a timekeeper gave a signal, and the reporter stopped and transcribed his notes, the reporters working in this way in rotation. The "copy" was passed on to the sub-editors slip by slip, and then on to the linotype operators, so that by the time Lord Rosebery reached the end of his speech only the last few lines remained to be set up in type. The speech was reported in its entirety in this manner, except for a few moments during which Lord Rosebery had lowered his voice or had turned away to one side. So efficiently, in fact, did the whole of the arrangements work that the "6.30 edition" of the *Evening News*, published some little time before 6.30, contained the complete report, and earlier editions contained as much as had been spoken up to a few minutes before their issue from the newspaper printing office. All concerned are to be greatly congratulated on the result.

Reporting Lord Rosebery's Speech at the "Evening News" Offices.

STORAGE BATTERY FOR A CRANE LOAD

An electric crane equipment recently installed at Southampton is of particular interest, as a storage battery is employed to take off the peaks in the load, and enable it to be dealt with by a comparatively small generating plant. The installation consists of a number of electric cranes, which have replaced the hydraulic cranes previously employed. They are equipped with grabs of a special type, with a capacity of 1½ tons each, and are capable of loading and unloading at an average rate of one ton per minute. The cranes, when working simultaneously, take an average current of 250 amperes,

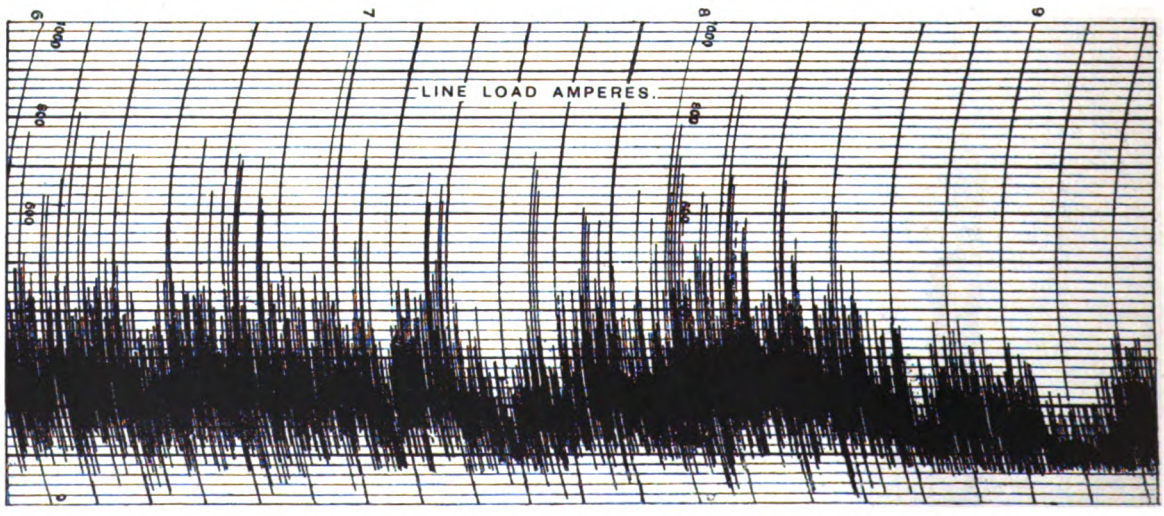

Fig. 1.—Chart of Line Load, Showing Fluctuations between 0 and 800 Amperes.

Digitized by Google

at a pressure of 500-525 volts. The consumption per ton is said to be about 0·5 unit. The fluctuations in the load are necessarily severe, the current varying within short intervals from 0 to 800 amperes. With the aid, however, of a battery and reversible booster, this load is very successfully dealt with by one 150-h.p. producer gas engine—another similar engine being in reserve. The engines are direct coupled to generators capable of an output of 192 amperes at 520 volts, with a 15 per cent. overload for half an hour. We are informed that the coal consumption with the engines working at full load is 1·5 lb. per kw.-hour.

The battery consists of 245 cells of the "D.P." Battery Co.'s standard "L.S." 15-plate type, in wood lead-lined boxes, capable of discharging at 500 amperes for one hour, or at 1,000 amperes for short periods. The positive plates are about half an inch thick, and very solidly constructed to stand the heavy rates of charge and discharge. The formation of the plates is the "D.P." Battery Co.'s special Planté process, and consists of a thin hard skin, which is claimed to be practically proof against disintegration. The cells are burnt up throughout, and the inter-row and terminal connections consist of 1 in. diameter copper rod. The battery is erected on single-tier stands, mounted on concrete blocks. The booster, made by the Lancashire Dynamo & Motor Co., is so adjusted that the engines can be set at any desired load, and all variations above or below this load are taken care of by the battery and booster. Some records taken at this station are shown in the accompanying figures. From these it will be seen that with the line load fluctuating from zero to 800 amperes, the variation in the generator load was only about 15 amperes above and below the mean. The generator was shut down for 10 minutes, and during this time the battery supplied the whole load.

The connections of the switchboard are so arranged that the battery can be put on to the line by itself, or in parallel with a generator. As an alternative arrangement, the battery and booster can take the load without the generators, the booster being adjusted so as to give an over-compounding effect. The battery and booster can also be put on the line in parallel with both generators. In the unlikely event of both sets being temporarily disabled, the battery could, we are informed, keep all the cranes going for over three hours, so that the station is amply safeguarded against an interruption of supply. Besides the advantages in respect to reliability gained by installing storage batteries, a very considerable economy is said to be effected in the size and first cost of the whole generating plant, in addition to the saving in daily working expenses and wear and tear of plant. The gas engines and generators were supplied by the British Westinghouse Co., Ltd. The battery, booster, switchboard, and cables were installed by the "D.P." Battery Co., Ltd., and the whole installation was designed by Messrs. Lacey, Sillar & Leigh.

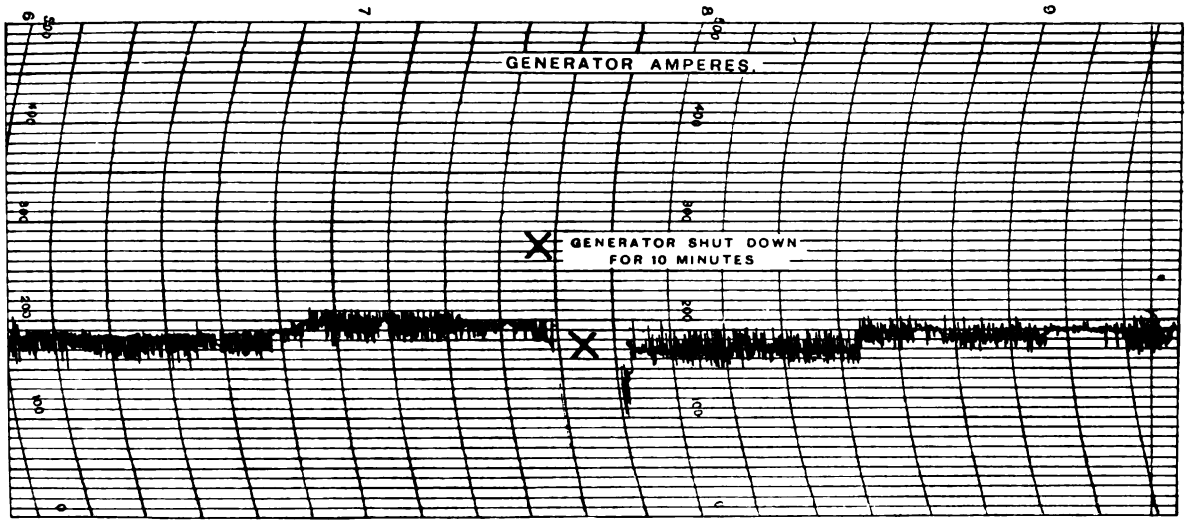

FIG. 2.—CHART OF GENERATOR LOAD, SHOWING FLUCTUATION OF ONLY 15 AMPERES ON EITHER SIDE OF THE AVERAGE LOAD.

STORAGE BATTERIES ON A.-C. SYSTEMS

The Load Regulating Plant at the Gary Steelworks, Indiana

IN a Paper by J. L. Woodbridge, read before the American Institute of Electrical Engineers, and abstracted in ELECTRICAL ENGINEERING, Dec. 3rd, 1908, Vol. IV., page 731, the author dealt with the application of storage batteries to the regulation of alternating-current loads, and in June last the same author read another Paper before the same Institution on the installation for this purpose in the works of the Indiana Steel Co., Gary, Indiana. The equipment of these works was described in ELECTRICAL ENGINEERING, Nov. 12th, 1908, Vol. IV., page 653, where a brief reference to the battery installation was made.

The battery consists of two series of cells, each series comprising 125 cells. Each cell contains 73 plates measuring $18\frac{5}{8}$ in. by $18\frac{5}{8}$ in., and has a capacity of 4,320 amperes at the hour rate, or 8,640 amperes at the usual regulating rate. This latter rate is more or less arbitrary, as the cells are capable of discharging momentarily at much higher rates under emergency conditions. The two series, operating in parallel, have thus a capacity of 8,640 ampere-hours at a one-hour discharge rate at a voltage which may vary from 225 down to 200, depending upon the state of the battery, &c. Discharges as high as 25,000 amperes have already been taken from the battery. It is installed in a two-story building, one series of cells being located on each floor. Each battery room measures 46 ft. by 80 ft. Forced ventilation is provided, the air being taken from outside and filtered through wet coke to remove all dirt and particles of iron. In order to provide for the automatic transfer of energy in either direction between the battery and the A.-C. circuit, two split-pole converters have been installed, each having a continuous rating of 6,800 amperes, direct current, in either direction, with a voltage range from 225 to 275 at the D.-C. brushes. These are six-phase machines arranged for double-delta connection to the secondaries of the transformers. The D.-C. terminals are connected directly across the battery without the interposition of any booster, and the variation of voltage is brought about by varying the distribution of field flux over the pole face.

One portion of each pole of each machine is used as an auxiliary or regulating section, its excitation being controlled automatically to produce the desired variation of direct voltage. The excitation for the main-pole section is obtained from the 250-pole exciter bus-bar, while the winding on the auxiliary-pole section receives current from a specially designed synchronous exciter, the theory of which was given in ELECTRICAL ENGINEERING of Dec. 3rd, 1908. In the accompanying figure, which is a simplified diagram of connections of the regulating apparatus at Gary, this excited is shown at *E*. The armature is provided with six collector rings connected to three current transformers *T* in the A.-C. circuit. The alternating currents thus transmitted through the armature winding will set up a revolving field proportional to these currents. A synchronous motor connected to the A.-C. circuit revolves the armature in a direction opposite to that of the field rotation, thus holding this field stationary in space. The machines are so designed that at unity power-factor this field will take the direction indicated by the arrow. There are two pairs of brushes on the commutator. One pair, called the auxiliary brushes, is short-circuited, and the other pair is connected to

Digitized by Google

the regulating field coil F of the converter. The fields of the exciter are provided with two windings. One of these is a shunt winding energised from the exciter bus-bars and controlled by a rheostat. The current in this winding may be adjusted to neutralise the field set up by the alternating current at some particular load on the A.-C. circuit. Under these conditions there will be no potential across the short-circuited brushes, but any change in the A.-C. load above or below the value for which the shunt field of the exciter has been adjusted will produce a difference of potential between them. A small change in the A.-C. load will be sufficient to cause a very considerable flow of current, and this will set up a second field at right angles to the main field. This second field produces a potential across the other brushes, and a corresponding flow of current in the regulating field F. If the load has increased, the direction of flow of current in the field coil F will be such as to cause the battery to discharge, while if the A.-C. load has decreased, the current in F will be in the opposite direction, causing the battery to charge. The second field winding on the exciter is connected in series with the field coil F, and serves to neutralise the armature reaction due to the current output from the exciter, and thus makes the machine more sensitive. The exciter is affected by the watt component of the load only, if the power-factor is not unity.

In the Gary installation this exciter is an eight-pole machine, the armature being provided with a four-pole winding, and is driven by a four-pole synchronous motor. There are eight brushes bearing upon the commutator; four are short-circuited, and four are connected in pairs. For supplying alternating current to the exciter, a current transformer is connected into each phase of each of the main generators. These current

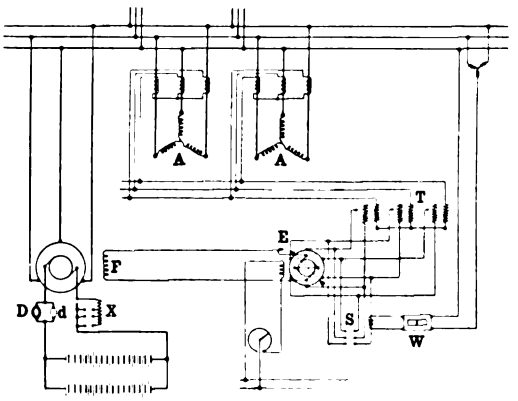

DIAGRAM OF CONNECTIONS OF THE BATTERY REGULATING PLANT AT THE GARY STEELWORKS.

transformers are connected to a set of common totalising bus-bars, which in turn are connected to the primaries of three totalising current transformers, T. The secondary windings of the latter are connected to the collector rings of the exciter. This arrangement was made necessary owing to the fact that the outgoing feeders are connected to the bus-bars at various intermediate points between the main generators, A, A.

One special feature of the apparatus is the short-circuiting switch S across the secondaries of the totalising current transformers. When this switch is closed, the current transformers and the exciter are short-circuited. This reduces the exciter D.C. voltage to zero and instantly kills the regulation, but owing to the high armature reaction of the exciter only a small current flows through the switch. In one of the leads to this short-circuit switch is connected the current coil of a wattmeter W, its voltage coil being suitably connected to indicate the energy component of the current passing through the short-circuiting switch. This wattmeter provides a means for adjusting the shunt field of the exciter to any predetermined average load on the generators before opening the short-circuiting switch.

To put this apparatus into service, the converter is started from the battery through the automatic starting resistance X and the circuit breaker d. The machine is then synchronised with the A.-C. bus-bars and the oil switch is closed. The closing of this switch automatically trips the starting circuit-breaker, d, cutting the converter free from the battery. The direct voltage of the converter is then adjusted by its main field rheostat and the running circuit breaker D is closed. The battery and converter are then floating on the alternating-current bus-bars. The exciter E is then started up and connected to the field F of the converter, the switch S being closed so that no voltage is developed in the exciter. The rheostat is now adjusted until the wattmeter W reads zero. If there is a fluctuating load on the alternators the wattmeter needle will be swinging on either side of zero, but the adjustment may be made so that when the load on the alternators is at the desired average value, the wattmeter W will read zero. When this adjustment is effected the switch S may be opened and the regulating apparatus will be in operation. The battery is also arranged to control fluctuations of load on the direct-current bus-bars, to which it is connected by means of two direct-current boosters which may be operated either singly or in parallel. These boosters are provided with carbon-regulator control in the usual manner.

Curves are given in the Paper which show that with a total load varying between 5,000 and 9,000 kw., the load on the generators was never more than 6,500 kw., the difference between this and the maximum of 9,000 kw. being supplied by the battery. The effect of the battery regulation on the operation of the entire plant, concludes the author, is very marked. In the first place the battery permits the shutting down of one 2,000-kw. gas-engine unit, which would be required if the battery were not in service. Even with this additional unit in service, the operation of the plant without the battery involves constant attention and a continual adjustment of generator field rheostats and engine governors. Without the battery in service, it is impossible to maintain satisfactory voltage regulation, and the speed of the engines is continually varying over a wide range, whereas with the battery in service the regulation of speed and voltage is all that could be desired. One of the most obvious of the practical commercial results is the increased speed at which the rolling mill may be operated. When the battery is not in service a very appreciable reduction in the daily output is observed, due to irregularity of speed and voltage. In addition to this regulating effect, the battery is an ever present source of energy to supply power in case of some emergency such as the sudden shutting down of one of the prime movers or any other partial interruption of the power supply. The vital necessity for continuous power supply to a steel rolling mill is well understood, and the effect of the battery in eliminating costly delays in the operation of the mill would undoubtedly warrant the fixed charges against the battery investment, even if these were not largely offset by the saving in investment for additional generating capacity which the battery replaces.

Northampton Polytechnic Institute. The new building is finished, and provides enlargement of the mechanical engineering workshop and of the mechanical laboratory, besides two new power laboratories, a new class-room capable of accommodating 280 students, and thirteen other class-rooms of various sizes. Besides the new classes in aeronautical engineering in the mechanical engineering department, there will be, in the electrical engineering department, a new class on the testing of electrical plant, conducted by Dr. C. V. Drysdale, in place of the advanced class on electrical instruments, which will not be held this session. There will also be a new class on electrical engineering quantities, and estimates, conducted by Mr. E. Kilburn Scott. In the section devoted to telephony and telegraphy, the class on submarine cable work, started last session, is to be continued, and the class on radio-telegraphy and telephony, conducted by Dr. J. Erskine Murray, will also be continued. There will also be special classes for the members of the Postal Telegraph Service, adapted to the departmental requirements. Courses in electrochemistry now take their place in the regular work of the Institute. Full particulars of these and of the other courses held at the Institute are given in the calendar for the coming session, which has just been published. The evening classes commence on September 27th, the day classes on October 4th.

The Illuminating Engineering Society. It is announced that Prof. S. P. Thompson, F.R.S., has consented to become the first president of this new society, which will enter upon its opening session next November.

The International Correspondence Schools. A banquet is to be held at the Hotel Cecil, London, on Saturday next to celebrate the eighteenth year of existence of this institution, which now has some 150,000 students actively following its courses. Students from all parts of the country have been invited by the directors to inspect the headquarters of the institution in Kingsway, London, and a reception will be held there in the afternoon. The Rt. Hon. Lord Montague of Beaulieu will take the chair at the dinner in the evening, and several other distinguished visitors will be present. The institution has branches in nearly all the British colonies, besides 50 branches in the United Kingdom, and the courses of instruction include a large number of technical subjects, besides business and general education. Instruction in electrical engineering forms an important section of the work done by these schools.

CORRESPONDENCE

BONDING AND EARTHING.

To the Editor of ELECTRICAL ENGINEERING.

Sir,—I have been interested in Mr. Sowter's remarks in your issue of July 15th regarding the importance of bonding and earthing of mains, more especially as his remarks apply to a mains system which is within two or three years of the age of the Bradford system.

Experience with an extensive three-wire network with unbonded services and mains has shown the absolute necessity of bonding the armouring, and making the lead sheath continuous. The troubles consequent on discharging and electrolysis, owing to the presence of innumerable short lengths of non-continuous sheathing, have been frequently experienced in Bradford. I enclose photos of two faults, both being representative of these troubles. The damage in each of these is due to the absence of bonding, but in the more recent example the destructive effect has not spread as far as in the other owing to the operation of the fuse-pillars recently installed, which split the network into a number of small sections. The photographs of the latter fault (Figs. 2, 3, and 4) show very clearly where the discharge has taken place between the unbonded cable and the glands of each of the three boxes.

The work of opening up old joints and bonding the same has been in progress for some time past, but un-

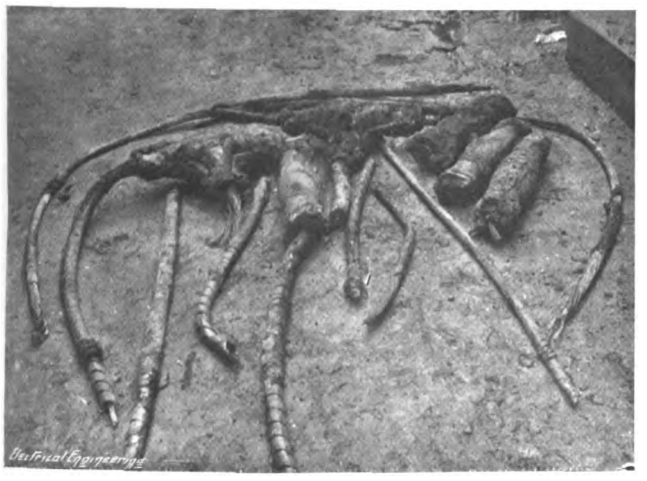

Fig. 1.—View of Faulty Cables and Joints from Hustlergate Fault at the bottom of Queensgate, November 21st, 1906.

fortunately the positions of all such joints were not charted in the early days. The installation of the fuse-pillars, however, has greatly reduced the amount of damage done when a fault occurs.

The earliest mains laid in Bradford were fibre-insulated, lead-covered, juted, and sometimes armoured, and although laid some twenty years, this cable whenever examined has been found perfect, and any trouble given is almost entirely through want of bonding or earthing. Paper-insulated cables have been laid since 1897, and for the past few years wire armour has been adopted in place of steel strip on account of its being better adapted to a perfect bond, this being accomplished by leaving the steel wires sufficiently long as to overlap, tinning the ends, and carefully soldering them in a copper sleeve.

There is an important point not referred to by Mr. Sowter, namely, the bonding of a number of cable sheaths together when laid direct in the ground and closely together, as shown in Fig. 5 (page 816). This bond has been made by removing a few inches of the armour, carefully cleaning and tinning each side of the gap thus formed, and scraping the lead sheaths. An alloy of lead, tin, and bismuth, so proportioned as to run easily below the melting points of the lead sheaths, is poured into a wooden mould, thus securely bonding everything together. In some cases as many as sixteen feeder cables have been treated thus, and where a number of mains pass under various tram routes, pilot wires have connected such bonds and tram-rails to a recorder at the generating station, this giving useful records of the potential difference and relative polarity of the rails and bonds. It has been considered advisable at certain points, after taking these readings, to permanently connect the rails and

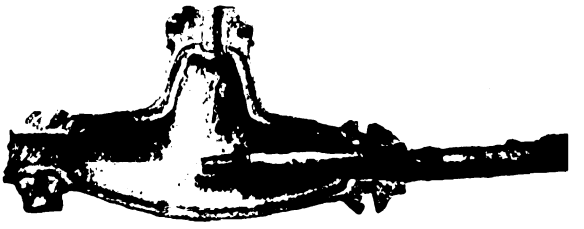

Fig. 2.

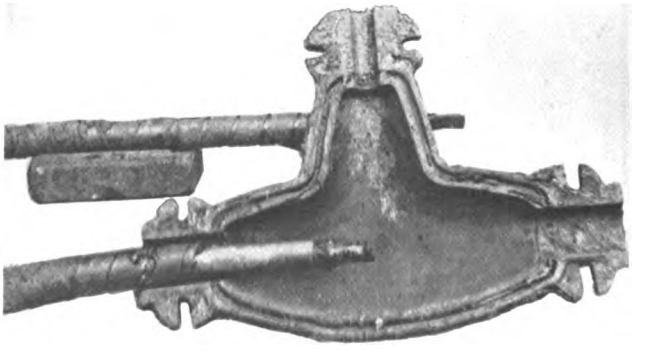

Fig. 3.

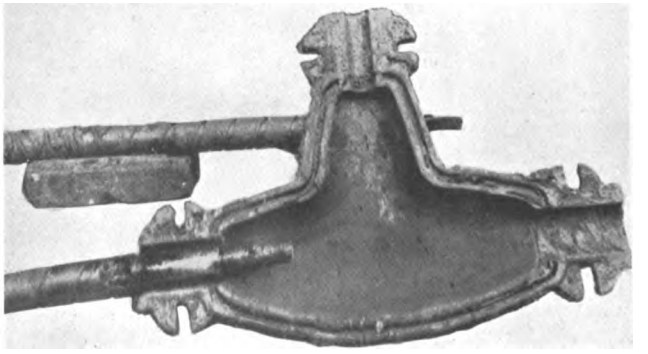

Fig. 4.

Figs. 2–4.—Photographs of Cable Faults at Hall Ings, September 5th, 1909.

bonds by a heavy copper conductor, thus entirely preventing electrolytic action.

The writer has tested the efficiency of an ordinary earth connection in Bradford, such as a 9-ft. length of cast-iron pipe buried in several loads of coke, and finds it to have a resistance of over 5 ohms. Such an earth would lead to disastrous results if relied upon, and it is obviously important that careful tests should be made of earth circuits before any reliance is placed upon them.

Mr. Sowter states that a concentric system should be concentric throughout. This is certainly a good scheme, and forms part of the rule coming into general

Digitized by Google

use that in mains systems all cores of different polarity should be bunched within a well-earthed and continuously-bonded metallic sheathing, the insulation between cores being an easy matter to contend with. By carrying this principle into effect, the difficulty of providing a return path for stray current from faults is in a large measure overcome.

Whilst speaking of many cores under one sheath, a recent experience with a six-core feeder may be interesting. This particular feeder, of which there are many in Bradford, contained the positive, negative, neutral, and the three pilot wires of the three-wire system. The monthly test aroused suspicion, and the feeder, not being urgently required in the summer

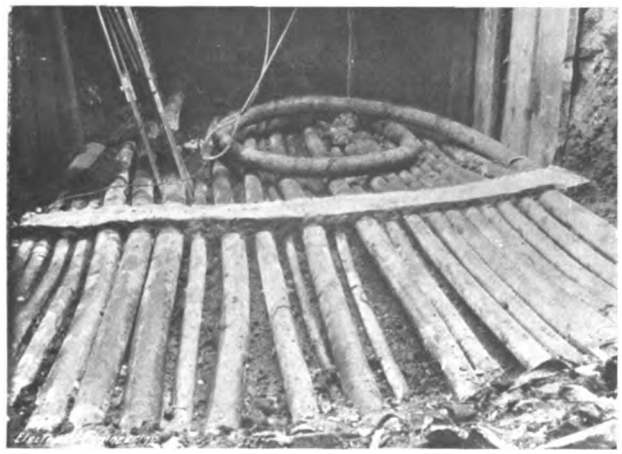

FIG. 5. VIEW OF BONDING AT THE BOTTOM OF BOLTON ROAD IN FORSTER SQUARE, FEBRUARY 9TH, 1906.

months, was left on a light fuse for a day or so. Later a five-ampere fuse on the negative pilot blew. This leakage on a small pilot wire gave sufficient drop to locate the fault (water in a joint) to a yard by a bridge test. I may say this fault was located and repaired before it had developed into anything approaching a burn, and it is certainly an argument in favour of bunching cores, as the opportunity of obtaining a location test is far better than with a single core.

Yours faithfully,

CHAS. W. SALT,
Assistant Electrical Engineer.

ELECTRICAL INSTALLATIONS IN COAL MINES.

To the Editor of ELECTRICAL ENGINEERING.

SIR, I have read the article on electric installation in coal mines in your issue of September 2nd, and I, of course, have heard that a small expert Committee is to be appointed to deal with the revision of the rules which were prepared five years ago. A very great deal of experience has been obtained in the last five years, particularly in connection with the underground distribution of three-phase high-voltage current, and also in the operation of coal-cutting machines, particularly with three-phase motors. A certain amount of doubt appears to exist at the present time as to the portion of a mine into which motors can be introduced where Rule No. 8 applies without total enclosure, and they are also not quite clear on the portions of a mine into which current at a higher voltage than 650 can be introduced with safety; and I think that these points, together with several others which have cropped up during the last five years, could with advantage be cleared up.

The bulk of the accidents which have occurred in mines have arisen from the use of coal-cutting machines, and some practical, useful rules as to the precautions which should be taken in the way of earthing and the class of cables to be used to ensure safety might, with considerable advantage to the electrical engineer as well as the user, be dealt with.

I am sending you copy of some notes which I made on the rules as prepared five years ago, which may perhaps be of some service to you, and shall be glad if you will accept them.

Yours faithfully,

W. C. MOUNTAIN.

Ernest Scott and Mountain, Ltd.,
Close Works, Gateshead-on-Tyne.
Sept. 8, 1909.

[The enclosure above referred to is a practically arranged book, in which each of the rules is printed in red and is followed by descriptive matter explaining its application. Illustrations of various suitable pieces of apparatus are also included. —ED. E. E.]

To the Editor of ELECTRICAL ENGINEERING.

SIR,—*Re* rules suggested for electrical installations in coal mines:—

Cables (*Lighting*).—A high grade of cables should be used, and protected with screwed conduit mechanically connected with all fittings, which should be gas-tight and water-tight, and glass parts protected with shields. The whole system of conduit to be efficiently earthed. No slotted conduit to be allowed.

Cables (*Power*).—Cables for power should be armoured. The armour to be mechanically and electrically connected throughout.

Joint Boxes.—Cast-iron boxes should be used of a good design, with double glands—one gland to go under the armour and over the cable, the other gland to go over the armour, and clamp it down to the under-gland; both glands then should be drawn up to the box proper with screws or bolts. Faces of under-gland and box-end to be machined. When armour is clamped to a box in this manner, great pressure is required to part the armour from the box, and, should a fall of roof occur, parting of the conductors is prevented. Mechanical connections should be used of good design, and have a powerful grip on the conductor. All joint-boxes should be filled with oil or compound which prevents gas or dust getting in the box through the strands of the armour, and should be fitted with drain-plugs. Link-boxes should have their connecting pillars mounted securely on thick ebonite bases, lifted well clear of the bottom of box. The armour should be copper, bonded over at the joint-boxes. A separate earth cable may be used and put to earth in the sump; where this is not provided, all motor-frames, switch and starting gear should be earth-bonded together, and finally bonded to the armour of the cable, which should be earthed in the sump. Earths made in the strata, in the workings, or haulage roads are of little or no use unless made in metallic seams or veins.

Erection.—Boxes should be erected on iron or wooden brackets well clear of the setts. These brackets should be strong enough to hold the box efficiently, and yet weak enough to break or give in case of anything striking them. Cables should be erected on light iron hooks fastened to spikes driven in the roof or timbers, or some other flexible hanger which will break when the roof comes in. Cables should not be passed over girders or timbers which support the roof, but erected under them.

Yours faithfully,

R. J. FROST.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to the remarks on page 777 of your issue of September 2nd, it is evident that there is a feeling in the country which is regarding the use of electricity in coal mines as a source of danger to miners and to property.

I notice that, as a rule, the defective cables are found to be the chief reason for fatalities. This is, perhaps, due to their exposed condition; also perhaps sometimes to the careless manner in which they are "slung"; also the difficulty of obtaining good joints. The question of earthing is a very important matter, as I know of instances where men have got considerable shocks from the rails, this being due to a portion of the strata through which the roadway runs having certain insulating properties. Efficient and proper earthing is of great importance.

The question of motors is one that requires a good deal of consideration, as at present there are several motors on the market known as flame-proof, but very few of them would really prove to be such in an atmosphere of explosive gas. The most abused piece of apparatus in the average colliery is the electric coal-cutter, and those who are familiar with the extremely rough handling these machines have to put up with are not surprised at the numerous breakdowns which occur. Many of these motors are dust-proof when sent from the factory, but after being in work for some little time, most of the joints require re-making. It would be very unwise to find fault with the man in charge of the machines, as frequently a competent individual at the colliery has so much machinery under his care that he is unable to devote sufficient time to each individual case.

I think the colliery managers would find a great saving if they would pay a better salary to obtain more competent men in charge of their plant, and have a closer system of inspection of the electrical machinery underground by individuals who have sufficient knowledge to make that inspection. This, I believe, is done in some collieries, and probably if it were extended to others the managers concerned would find that their foresight would be amply repaid.

We do not want any more legislation in connection with electrical apparatus, as I am afraid that it is being made a scapegoat for accidents and explosions for which no other solution can be found, and the installation of electrical plant has been delayed in several instances owing to such mis-statements.

Yours faithfully,
H. C. JENKINS.

The Mining Engineering Co., Ltd., Foster's Buildings, High Street, Sheffield.

[Owing to pressure on our space, we are obliged to hold over until next week several interesting letters on this subject.—ED. E. E.]

THE SPEED OF TURBINE SETS.

The Sydney Corporation invited tenders for 4,000-kw. turbine sets running at a speed of 750 r.p.m. Alternative tenders were received for machines running at 1,500 r.p.m. at a much cheaper price. In spite of the City Electrical Engineer's preference for the slower speed, the Corporation decided to invite fresh tenders for machines at 1,500 r.p.m. from all the firms competing. We are inviting the opinions of some of the leading turbine manufacturers on this question of turbine speeds:—

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In reply to your letter of the 10th inst., I might say that the information contained in your columns is not quite correct.

The Sydney authorities advertised for two 4,000-kw. turbines running at a speed of 750 r.p.m. The speed which was offered by certain of the competing firms was 1,500 r.p.m., and their offer at the higher speed was some £12,000 less than the offers for the turbines at the specified speed of 750 r.p.m. In other words, whereas the price of the tender recommended for acceptance by the engineer was some £44,000, the price of the lowest offer was some £32,000.

As fresh tenders have been called for from all of the competing firms for a speed of 1,500 r.p.m., it would be out of place for me to offer any criticism on the relative merits of the two speeds at the present time. It can, however, be stated generally that some purchasers would seem to be adopting a doubtful policy in considering turbines running at speeds which are abnormally high in comparison with the speeds hitherto adopted.

The excessive competition existing at the present time between manufacturers, at home and on the Continent, has brought about not only an abnormal cutting of prices when bidding on the same type of plant, but, what is probably worse, an increase in speeds, in order to enable a smaller size of plant to be offered for achieving the same results.

It is certain that purchasers at a later stage will, under these circumstances, not be justified in blaming the turbine as a prime mover if the running and maintenance charges are heavier than they had anticipated, for blame will be due to their own judgment in sacrificing other considerations to a further reduction in capital cost.

And in considering this question of capital cost, sight should not be lost of the fact that already the turbine, as a prime mover, has enabled the capital cost of a generating station to be reduced by over one-half, and this without adopting the abnormally high speeds which some manufacturers are advocating as a temporary means of meeting competition.

That higher speeds will come in time no one doubts, for first cost and steam consumption are both in favour of a high speed; but it can scarcely be stated that the advocates of abnormal high-speed turbines have up to now met with success, and it would seem as if any advancement in this direction were better made at home than abroad, where the continuity of supply depends so largely upon the reliability of the plant, and, in the event of trouble, upon speedy repairs.

Yours faithfully,
E. J. FOX.

Rugby, *Sept.* 13, 1909.

To the Editor of ELECTRICAL ENGINEERING.

SIR.—We duly received your favour of 10th inst. *re* a machine of this size, and beg to say that the speed of the turbine which we should adopt for a unit of this size would be 1,500 r.p.m., if this speed suits the frequency of the current to be generated.

Yours very truly,
For Greenwood & Batley, Ltd.,
S. T. BATLEY,
Director.

Leeds, *Sept.* 13, 1909.

New Pattern of Electric Flasher.—Mr. C. H. Jukes-Browne has sent us a description of a thermal switch for illuminated signs, which he has patented. The novel feature of the switch is that the intervals between switching on and off, and *vice versa*, can be varied between, say, seven seconds and 2½ minutes. It consists of a zinc tube fixed at one end, and heated up by a coil of resistance wire. When the tube expands, it acts on a lever, giving a large amplification of the movement. The lever is fitted with two adjustable contact screws which come in contact with a pivoted arm, and intermittently short-circuit the heating coil. Mr. Jukes-Browne, whose address is 76 Weston Road, Strood, Kent, wishes to make arrangements for the manufacture of this flasher.

WIRELESS TELEGRAPH NOTES

IN reply to a question in the House of Commons, Mr. Churchill has again stated that the missing ship *Waratah* was not supplied with wireless apparatus, and that he does not think the time has come to make the installation of wireless apparatus on board ship obligatory.

Mr. Henniker Heaton has given notice of a motion calling attention to the neglect of Imperial and foreign telegraphic communications. He urges the abolition of political frontiers for wireless communications, and the consideration of the offer of the Marconi Co. for the establishment of a penny-per-word wireless system between the United Kingdom and Italy.

With regard to the present negotiations between the Post Office and the Marconi Co., mentioned in our last issue, the *Financial Times* states that, under the proposed agreement, the Post Office will extend its business to the transmission of messages to ships at sea, and will acquire the right to use the Marconi system between the mainland and outlying islands, such as the Scilly Islands, the Orkneys, &c. The Transatlantic business will remain in the hands of the company, which may also organise the transmission of wireless messages between important cities like London, Liverpool, Dublin, and Cork.

A wireless telegraphy station has recently been provided for experimental purposes in connection with the physical department of the Armstrong College, Newcastle-on-Tyne, under licence from the Postmaster-General. A description in last week's *Times Engineering Supplement* states that in the construction of the antenna about 1,500 ft. of 7/20 silicium bronze wire was used. A double length of this wire, about 170 ft. long between the insulators, is stretched between two towers of the college, 150 and 80 ft. high respectively. Other lengths of cable are led from these to the instrument room. By means of a change-over switch, the aerial can be connected to either a spark transmitter, or a Poulsen arc transmitter, or earth, or the receiving circuit. For spark transmission an 18-in. induction coil is employed, which can be excited from the city a.c. 100-volt mains, or, with the aid of a suitable break, from a storage battery. Communications have already passed very successfully between the Armstrong College and the Cullercoats station. The College station is under the direction of Professor H. Stroud and Mr. H. Morris-Airey, who have had the benefit of the technical advice of Mr. A. Sörensen, engineer and manager of the wireless station at Cullercoats, near Tynemouth.

According to an American Consular report, the Uruguay Government intends to erect three wireless stations, at Flores Island, Punta del Este, and Cape Santa Maria, respectively. A concession has been granted to the Marconi Co., of Buenos Aires, to erect a station at Punta del Este, but no progress with this station has been reported. A station which has a radius of 311 miles has been in operation on El Cerro, Montevideo, since 1904. The instruments are of the Schreiber and Hörer make. It is further stated that there is only one wireless station in Chile, situated at the naval school, in Valparaiso. The limit of range is said to be 200 miles. All cable messages at present go *via* the Argentine, and the Government has long had under consideration the establishment of wireless stations at Valparaiso, on the island of Juan Fernandez, and at Punta Arenas, but there is no active project on foot.

In another American Consular report, the following details of some French stations are given. The Saintes Maries station, in the department of Bouches-du-Rhone, has a normal wave length of nearly 2,000 ft. and a working radius of 370 miles. Messages have, however, been transmitted from this station to Casablanca, Algeria. The Fort de L'Eau (Bay of Algiers) station has about the same wave length and radius, while the stations at Ile d'Ouessant and Ile de Parquerolles have each a radius of about 120 miles.

According to the American Consul for the Nagasaki district in Japan, there are two wireless stations in that district under control of the Department of Communications, one located at Osesaki, on the southernmost extremity of the Goto Islands, and the other at Tsunoshima. The wave lengths are 984 ft., and the working radius of each station 137 miles.

An account of a demonstration of a new automatic transmitter for wireless telegraphy, which took place on Saturday last at the Cullercoats station, was given in the *Times* of Monday. Among those present were Major S. C. Long, of the Signal Corps; Mr. H. A. Kirk, representing the India Office; Mr. Arthur Silvertop, representing the Admiralty; Mr. Preece, of Messrs. Preece & Cardew, representing the High Commissioner for New Zealand; and Mr. F. Ryan, representing the Eastern Telegraph Co. The Cullercoats station is fitted for working with both the de Forest spark system and the Poulsen arc system of radiotelegraphy, but it is for the latter that the high-speed transmitter is adapted. The object of Saturday's demonstration was to show that, with the employment of an automatic transmitter, working more or less on the same principle as the Wheatstone automatic telegraph system, a speed of sending can be obtained rivalling that realised with submarine cables. The detector used on Saturday consisted of a piece of tellurium pressed lightly against a surface of galena. This was connected to a sensitive mirror galvanometer by means of which the messages were recorded photographically on a strip of sensitised paper. The automatic transmitter was not on view at Cullercoats, but was erected at Lyngby, in Denmark (600 miles distant). A message of 27 words was transmitted with the ordinary hand-key to Lyngby, and after being punched there was returned by the automatic transmitter at a speed of 50 words a minute. Finally, this same message was transmitted several times over at a speed which well exceeded 100 words a minute. It was read by an operator who had not seen the original, and it was found to be perfectly clear and accurate with the exception of one or two letters. The power employed at Lyngby was understood to be 10 h.p., and the wave length was 1,800 metres. Dr. Poulsen and his associates anticipate that they will succeed in telegraphing across the Atlantic at a speed of at least 50 words a minute with the expenditure of 100 h.p., whereas the present speed of wireless working across the Atlantic is 25 words a minute.

The Durban correspondent of the *Daily Mail* states that experiments are about to be made with a view to establishing wireless communication between England and South Africa. It is proposed, he writes, to use kites at an elevation of 1,000 ft. to receive messages from the Bolt Head and Poldhu stations in England, but, if this is unsuccessful, the erection of an intermediate station at Gibraltar at a cost of £50,000 is proposed. He adds that the tariff for general commercial service will be one shilling per word.

The Direct West India Cable Co., in the course of trials with the wireless installation erected at Kingston, Jamaica, has got into communication with steamers at distances of 120 and 75 miles from that city. Difficulties are, however, being experienced in receiving calls from ships until they reach the neighbourhood of Port Royal.

In connection with the proposed new Antarctic expedition, Captain Scott contemplates the use of wireless apparatus to provide a means of communication between the exploring parties and the ship. Mr. Marconi is reported in the *Times* to have said that the scheme was quite feasible. With an apparatus weighing about 56 lbs., and the use of kites to elevate the aerial wires, messages could, he said, be despatched and received over a distance of 200 miles.

THE NEW PROFESSOR OF ELECTRICAL ENGINEERING AT THE CENTRAL TECHNICAL COLLEGE

ON the resumption of work at the Central Technical College, South Kensington, at the commencement of the forthcoming session on October 5th, Mr. T. Mather will take up his duties as Professor of Electrical Engineering in succession to the late Prof. W. E. Ayrton, and Mr. G. W. O. Howe will fill the post of Assistant Professor. Both of these appointments have been made during the vacation.

MR. T. MATHER was elected a member of the Council of the Institution of Electrical Engineers in 1908, and his connection with the late Prof. Ayrton dates from 1882, when he was appointed his assistant at the Finsbury Technical College. He was elected a Fellow of the Royal Society in 1902. The principal subject of his more recent researches has been measuring instruments, particularly those of the electrostatic type. Among numerous Papers of which he is the author or joint author are two on "Galvanometers," read before the Physical Society in 1890 and 1898. The Ayrton-Mather galvanometer was also described in another Paper in 1890. As co-author with Prof. Ayrton, he read the following Papers before the Institution of Electrical Engineers in 1894:—"A Universal Shunt-box for Galvanometers," "Transparent Conducting Screens for Electric and Other Apparatus," and "An Astatic Station Voltmeter." Mr. Mather served apprenticeship with two Lancashire engineering firms, and studied at Owen's College, Manchester, and afterwards at the Royal College of Science, obtaining several distinctions. Mr. Mather was recently appointed a member of the Board of Studies in Civil and Mechanical Engineering in the University of London, and was "Internal Examiner" in the last B.Sc. examination in electrical subjects.

During the period of over twenty years that Mr. Mather has been chief demonstrator in the electrical engineering department of the Central Technical College, he earned a well-deserved popularity, and his

Digitized by Google

new appointment will be welcomed alike by present and past students.

Mr. G. W. O. Howe was for seven years with Messrs. Siemens Brothers at Woolwich, mainly in the cable department, after which, from 1900 to 1902, he worked in the designing and experimental departments of the Charlottenburg works of Messrs. Siemens & Halske, and returned for a few months to Woolwich. He was a student of the Armstrong College, Newcastle-on-Tyne, and graduated to the degrees of B.Sc. and M.Sc. of Durham University. Like Prof. Mather, he was the senior Whitworth Scholar of his year. Previous to his appointment as lecturer at the Central Technical College in 1905 he was for two years lecturer at the Hull Municipal Technical College. Mr. Howe is a member of the Technical Committee of the Elektrotechnischer Verein (Berlin).

MISCELLANEOUS APPLICATIONS OF ELECTRICITY IN MINES

THE second report of the Royal Commission on Mines, which has just been issued, contains several references to the use of electricity in collieries. The Commission in question was appointed in June, 1906, and included in the terms of reference there was an instruction to investigate what steps should be taken for the better prevention of accidents from the use of firing explosives, and they were also asked to report whether the present system of "special rules" is adequate. The Commission was under the chairmanship of Lord Monkswell. The first report, issued in May, 1907, contained preliminary observations on the subject of the use of breathing appliances, but the second report refers to some matters which are directly concerned with the use of electricity in mines, especially shot firing.

The Commission have come to the conclusion that it is not necessary to prohibit shot firing on the main haulage roads and intakes altogether, but they agree that it should be confined within as narrow limits as possible, and subjected to the strictest precautions. Captain A. H. Desborough stated, in his evidence, that it was his firm conviction that electric firing is considerably safer than any other method, and that the few accidents that occur with it are likely to decrease when the workmen get more accustomed to it. A certain number of miss-fires occur with electric firing, but with the continued improvement of electric detonators these are constantly diminishing. The use of igniter fuses (the other alternative allowed by the Home Office) in the case of permitted explosives, he considered unsatisfactory. Other witnesses also expressed themselves in favour of electric firing, and of the prohibition of igniter-fuses, and the Commission think that electric firing should be made universal in the case of permitted explosives. They also agree with Captain Desborough that the use of magneto machines is to be preferred to primary batteries. Other explosives than permitted explosives should, they recommend, be fired either by electricity or by a proper safety fuse, and the use of straws and squibs should be prohibited.

Several witnesses agreed that hang-fires were possible, although rare, with electrical exploders. Mr. W. Maurice has issued a rule for the Hucknall-Torkard Collieries that a miss-shot shall not be approached until five minutes of the time of disconnecting the exploder, and Captain Desborough said he had been able at Woolwich to produce electrical hang-fires, but they had never lasted for more than a minute, in which case he thought it was entirely due to the explosive itself. Electrical hang-fires, he said, are caused in two or three ways. One cause is a weak detonator which sets fire to the cartridge without detonating. The cartridge will burn until sufficient pressure is obtained to cause it to explode. Another possible cause is the detonator becoming detached from the cartridge during the act of ramming it home, and, on firing, the flash from the detonator will fire the cartridge, and one has to wait until sufficient pressure is exerted to explode the remainder, as in the other case. He thinks that an interval of ten minutes would be sufficient to show whether it was a case of miss-fire or only a hang-fire.

The attention of the Commission was called to the need for improvement in the locking of safety lamps. It was generally agreed that the "screw lock" was unsatisfactory, but according to the last annual general report there are still 79,741 lamps locked with screws, as compared with 393,605 locked by means of lead rivets, and 122,042 locked with magnetic lockets.

As to the electric re-lighting of safety lamps, No. 54 of the Special Rules for the use of electricity provides that "all electrical re-lighting apparatus shall be securely locked, so as not to be available for use except by persons authorised by the manager to re-light safety lamps, and such persons shall examine all safety lamps brought for re-lighting before they are re-issued." An arbitration recently took place between the Home Office and a firm of colliery owners in South Wales who objected to the application of this rule at their collieries, as they wished to allow miners to re-light their own lamps in an apparatus which was considered to be perfectly safe. A considerable amount of expert evidence was given at the arbitration, with the result that the umpire decided that the rule should be established. The result of this arbitration was to confirm the principle mentioned above, that safety lamps, before being re-lighted underground, should be examined.

One of the appendices to the report contains a criticism of the Engines and Boilers (Persons in Charge) Bill, by Mr. T. W. Casey, of the Yorkshire and County Enginemen and Motormen's Protection Association. In the course of his remarks, he says: At some collieries there is winding done by electric power as well as by steam power; in either case boiler power is essential. In the case of the winding machinery, the motive power of which is electricity, there must first be the boiler for the production of steam, the person in charge of which must needs have a first-class certificate. The steam is then transmitted to the steam engines driving the electric generators, but the person in charge of these only needs to possess a second class certificate; from these latter machines electric energy or current is produced, which is then transmitted to the motor winding gear, but the man in charge of this needs to have no certificate at all, though he may have men's lives in his hands, and winding out of what the Bill calls the 'shaft of a mine.' Still, there is no need for this man to obtain a certificate of qualification. Thus, on the one hand, though the engines only be 5 h.p., but the motive power of which is steam, the person in charge must have a first-class certificate; on the other hand, if the winding machinery is driven by electric power, and such machinery is equal to even 500 h.p., the person in charge would be exempt from qualifying at all. I think I have said sufficient on this point to prove how inconsistent and illogical is the basis upon which this measure is constructed.

There is also an appendix dealing with the organisation of rescue work in which quotations are made from a Paper read by Mr. W. E. Garforth before the International Life Saving Congress held at Frankfort in 1908. Among the suggested precautions to be taken is that in addition to the safety lamps in ordinary use, a supply of portable electric lamps should be in readiness, and that to ensure their being kept in working order they should be used daily for the examination of the shaft and underground machinery.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

HEATING AND COOKING APPARATUS.—A very complete catalogue of electric heating and cooking apparatus on the "Eclipse" system, has been issued by the Electric & Ordnance Accessories Co., Ltd. (Cheston Road, Aston, Birmingham). The heating unit used in this system consists of a special resistance material insulated with mica and enclosed in a thin metal casing, which, we are informed, will withstand a temperature of 2,500° Fahr. without risk of breakdown. The apparatus listed includes kettles, jugs, glue-pots, hot-plates, plate warmers, flat-irons, curling-tong heaters, and cigar lighters. These last consist of a miniature arc lamp, which is brought into action by pulling a chain, and should be useful for the entrance halls of hotels, clubs, and for tobacconists' shops. Most of the above apparatus is capable of being adjusted to give from one to four different degrees of heat by a slight manipulation of the plugs. In addition to general particulars, the catalogue contains a table showing the cost of operating the apparatus. The company are shortly bringing out a series of grills, ovens, toast racks, &c., in which the units will consists of resistance material capable of being run at a red-heat.

MOTOR CONVERTERS.—Messrs. Bruce, Peebles & Co., Ltd., of Edinburgh, have issued a pamphlet describing the Peebles motor converters which are manufactured under the La Cour patents. A number of installations where these machines are in use are illustrated, and some curves giving the characteristics of the machines are included. A comparison of motor converters with rotary converters and motor generators with regard to efficiency, regulation, power factor, and other points is given, and in conclusion a list of contracts for these machines, totalling to over 100,000 kw., is appended. The machine was fully described and discussed at the Institution of Electrical Engineers last session (see Electrical Engineering, May 13th, 1909, page 447).

WIRES AND CABLES.—Messrs. Pirelli, Ltd. (45 Basinghall Street, London, E.C.) have published a comprehensive catalogue of their cables and wires. In the section relating to underground cables, some interesting tests of high-tension cable are mentioned; one cable shown at the 1906 Milan Exhibition was run at a working pressure of 150,000 volts, and samples which were tested withstood 200,000 volts before breaking down. Another cable, with 72 sq. mm. conductors, insulated with V.I.R. and G.P., and then armoured with steel wire, has been laid across the Lake of Garda, and works at 13,000 volts: samples of this cable, it is announced, have been tested up to 100,000 volts without the dielectric breaking down. The part of the catalogue devoted to ordinary wires for house installation deals with every class of wire and cable, and forms a useful book of reference for prices; the large number of classes of "flexible" listed is particularly noticeable. Wires for tele-

Digitized by Google

phones, shot firing, instruments, bells, and motor-cars are all included in the catalogue.

MERCHANT VENTURERS' TECHNICAL COLLEGE, BRISTOL.—A preliminary prospectus of the courses in engineering to be provided in this college during the next session is to hand. Prof. David Robertson is head of the department of electrical engineering, and he is assisted by Messrs. O. J. Williams and H. Stanley. Mr. G. Mogg, of the Postal Telegraphs, lectures on telegraphy, and Mr. C. E. Morgan, of the National Telephone Co., on telephony. The session commenced on Tuesday last. Both day and evening classes are held, and special courses for the University degrees in engineering have been arranged in each case. The complete calendar will be published shortly.

ADAPTORS FOR SERIES WIRING.—A pamphlet is to hand from C. W. Richardson (159 Worsley Road, Patricroft, near Manchester), describing an adaptor in the shape of an ordinary lamp holder, but with one plug contact only at the plug end and a hole in the side for the insertion of a single flexible wire into one of the two plungers in the lamp end. Intermediate adaptors with no contacts but with holes for attaching wires to both plungers can also be obtained. Flexible wire, insulated screw-eyes, and insulated clips for use with these adaptors are also listed.

MOTORS AND DYNAMOS.—We have received from the J.-L. Manufacturing Co., Ltd. (Johnson-Lundell Works, Southall, Middlesex), a number of leaflets assembled in an artistic board cover, relating to the firm's patent laminated field motors and dynamos. The constructional features of the machines are described and illustrated, and particulars and prices of motors up to 75 b.h.p. and for various voltages are given. Dynamos up to 40 kw. output are listed, and illustrations of an oil-engine set, a portable motor with regulating switchgear, and other specialities are included.

RADIATORS.—Messrs. Veritys, Ltd. (Aston, Birmingham), have issued their new season's radiator catalogue in the form of a neat and attractive booklet. Several new designs are included, amongst which is the new pattern non-luminous radiator as used on H.M. battleships and cruisers.

MOTORS, CONTROLLERS, &c.—Among new lists issued by the Electrical Co. (121–5 Charing Cross Road) is one dealing with three-phase induction motors up to 6 b.h.p. Another list contains prices of lift controller equipments and component parts, including lever or rope control apparatus, automatic reversing controllers, and lift equipments for push-button or lever control. A third new list includes starters for continuous-current motors up to 25 b.h.p.

INSULATING TAPES.—Messrs. William Geipel & Co. (72A St. Thomas Street, S.E.) have sent us a sample of Okonite tape, which they claim, in spite of its much lower price, to be preferable to pure rubber for insulation of joints. They have also sent us a sample and particulars of their Manson tape, which is a self-adhesive black tape for protecting joints after they have been insulated with pure rubber or okonite. The latter is also a convenient material for insulating temporary work, protecting open ends of cable, &c.

Telegraph Traffic.—The cable between Mole-St. Nicolas and Cape Hayti was temporarily interrupted on the 7th inst.; this cut off communication *viâ* Key West-Hayti with the French West India system.—The line between Rome and Constantinople failed, but was restored again on the 7th inst.—On the following day direct telegraphic facilities ceased between Saigon and Bangkok, and telegrams are being forwarded *viâ* Obone, subject to delay.—The Bagdad-Bassorah line became interrupted on 9th inst., and was repaired on the 12th inst.—The cable between Tangier and Cadiz was put into working order on the 10th inst., and thus the routes of the Eastern and Direct Spanish Telegraph Companies to Tangier, Casablanca, Mogador, and Rabat are now all restored.—On the 11th inst. the Saigon-Bangkok line was again working.—A new telegraphic station has been opened at Porlamar in Margarita, an island of the coast of, and belonging to, Venezuela. The rate per word is the same as to Venezuela.—The River Plate Co. has made an offer to the Argentine Government to lay a cable direct from Buenos Aires *viâ* Tristan da Cunha to Europe.—The concession obtained by the Western Telegraph Co. gives them a monopoly of Government messages, and unrouted traffic for 25 years, but whether the objections raised by Germany have had any weight with the Government is not yet known.—On the 13th inst. the line between Bagdad and Bassorah was again worinkg, but the El Arich route, although open to receive messages, was subject to delay.—According to the *Times*, the Russian Government have agreed to the introduction of a Press tariff over the Siberian telegraph lines, so that the Great Northern Telegraph Co. will shortly be able to accept Press messages for China, Japan, and the Philippines at the rates prevailing on the Eastern Telegraph system.—Mr. Henniker Heaton has given notice of a motion in Parliament to call attention to the neglect of telegraphic communications. He suggests the appointment of an Imperial as well as a home Postmaster-General, and refers to several anomalies in foreign and Colonial telegraph rates.

ITALIAN REPORT ON THE CONFERENCE ON ELECTRICAL UNITS

PROF. ANTONIO ROITI, who was one of the Italian delegates to the International Conference on Electrical Units and Standards held in London in October, 1908, has now issued his report to the Italian Minister of Agriculture, Industry, and Commerce. A full account of the proceedings of the conference appeared in ELECTRICAL ENGINEERING of October 15th, 22nd, and 29th, 1908 (pages 543, 564, and 597). The principal resolutions passed specified certain values for the standard international ohm and ampere in terms respectively of the dimensions of a column of mercury and the deposit obtained in a silver voltameter. Certain specifications relating to standard cells were also agreed upon, and the establishment of a permanent commission was recommended.

Prof. Roiti, in speaking of the adoption of the ampere as the second fundamental unit, supports the view expressed by the representatives of France, America, and Sweden-Denmark, that the volt has distinct claims to adoption as the second fundamental unit. But historical continuity and consideration for standards already constructed carried the day in favour of the ampere.

With regard to the quantitative definition of primary units, he considers that the quickest and most logical method would have been to declare that two numbers of four figures each, having an undoubted agreement with the theoretical absolute values of the ohm and the ampere, are sufficient for definition, and to abandon definitely any idea of further approximation. The length of the mercury ohm was fixed at 106·300 cm. The two zeros were added to perpetuate existing standards. The resolution prevents any future approximation to the absolute ohm.

France and America alone supported the proposal to adopt an "absolute" current standard. The proposal to add figures to the electrochemical equivalent of silver gave rise to a long and complicated discussion. The Technical Sub-Committee, he points out, practically adopted two definitions of the ampere, one for ordinary use, and the other for more refined measurements.

The Conference remedied this by adding two zeros to the chemical equivalent of silver, making it 0·00111800. This resolution was opposed by France, Italy, and Canada, and many of the majority only voted for it as the only course likely to be adopted which would secure the necessary uniformity. But the question was raised again, and, although the resolution was eventually adopted, it only secured 13 votes instead of 21 as before.

This, he remarks, leaves the Chicago ampere practically unaltered. The addition, he says, of the zeros after a heated discussion will render the London Conference memorable as the Two Zeros Conference. "But I," he continues, "one of the most resolute opponents, do not wish to exaggerate. I repeat that at bottom this is only a question of form. But I adhere to my belief that he who has not been present at the meetings and has not read the verbatim reports, will, after a simple perusal of the final report, remain in doubt concerning the sense to be attached to these two zeros." . . . "The simple love of symmetry does not justify us in carrying all the numbers to six figures because the density of mercury is expressed by six."

He considers that it might be understood from the resolution that the concrete ohm and ampere standards must not differ from the international standards by more than 10 millionths. But, if so, it would be impossible to carry this out for probably a number of years. Or, it might be understood that the various national standards must agree within this value. This might be possible as regards the electrodynamic balance, and is certainly possible as regards the ohm. In any case, the degree of approximation had better been stated in the specifications than in the definitions.

Prof. Roiti himself introduced a proposal to insert a declaration making this question clear, but it only came up towards the end of the Conference, and it was considered simpler to regard the meaning of the two zeros as clear without further explanation.

I trust, he writes, that the Permanent Commission will see the necessity of giving effect to my proposal in some form or other in order to secure the real benefit of the "blamed zeros" (*zeri biasimiti*). I do not consider it necessary to introduce them into the text of the law, seeing that, on the example of Germany, the absolute electromagnetic system is not mentioned: and the task of defining the limits within which the two prototype standards must keep in accordance with the explicit recommendations of the London Conference, is best left to a Royal decree. But in this matter I submit to the judgment of our Ministerial Electric Standards Committee.

ELECTROLYTIC TROUBLES FROM STRAY TRACTION CURRENTS

Serious Damage to Water Pipes and Telephone Cables in Winnipeg

IN accordance with a resolution of the Council of the City of Winnipeg, Canada, passed in January of this year, Prof. L. A. Herdt has investigated the causes and effects of the electrolytic troubles in the city, to which attention had been called, and has prepared a report on his work. It appears that there has been considerable deterioration of the underground water mains and telephone cables in the central portion of the city, and it is stated to have been caused by the stray currents from the Winnipeg electric railway system, consequent upon poor bonding of the rail joints, and too high current densities in the rails. The following is an abstract of the report, which is given in full in the current issue of the *Canadian Electrical News*.

The Winnipeg Street Railway Co. have two plants in the City of Winnipeg—one, the old steam plant at the foot of Main Street; the other, the sub-station in Mill Street. The first plant is kept as a steam reserve; the second plant, which furnishes the whole of the current for the street railway system, receives its electrical energy from the water-power plant at Pinawa Channel on the Winnipeg River. The average current for the railway service approximates 6,000 amperes, but reaches as high as 9,000 amperes at times of heavy load in the winter months. The street railway tracks are bonded at several points to return feeders connected to the negative 'bus-bars at the station, but it was apprehended at once from a study of the general conditions that unless the track returns were of the very best, and the negative feeders of large section, the conditions were such as to point to great possibilities for stray currents.

The electrolysis survey which was carried out involved readings of potential differences between the rails, the piping system and telephone cables, an examination of the feeding circuits, road-bed, and the return, and a thorough examination of the points where damage to the pipes had been reported. The damage reported in some districts was found to be caused by the very bad condition of the bonding. In one place, where the road-bed was unpaved, the bond wires, which are No. 0, B. & S. gauge, soft copper wire with bonding cap terminal, gave readings in equivalent feet of rail of 20 to 60 feet, which shows a very bad condition of bonding. At several places the bonds are uncovered, and many broken bonds were noticed. Current is leaving the tracks where the rails are positive to the pipes, entering the pipes, flowing down these until Main Street is reached, (along Main Street the pipes are positive to rails), where the current leaves the pipes to rails, telephone cables, or other pipes causing the damage reported. In another district, close to the river, the rails are bonded to the water pipes. Here the heavy water mains carry a large part of the railway current, and the stray currents are given back to the telephone cables which are bonded to the negative 'bus-bars of the sub-station on Mill Street, and also to the intricate network of mains and service pipes lying in this district. In a certain building visited, a recording amperemeter was connected between the water main and the telephone cable in the basement, and charts of current readings were kept. At the time of the visit 50 amperes were recorded, and the water pipes were positive to the telephone cables. Prof. Herdt points out here that the bonding of the tracks with water and gas pipes, although it may afford local protection, will greatly increase the amount of stray currents, and should not be encouraged.

Prof. Herdt continues:—The bonding of the tracks on Main Street is good. In addition to the rails, which are heavy (70 and 95 lbs. to the yard), a 500,000 cir. mil. cable runs between the rails, and is cross bonded to the track. On account of the bad condition of the track returns in the other parts of the city, causing stray currents everywhere, the tracks in Main Street, connected to the 'bus-bars through heavy copper returns, draw the currents from the piping along this street. This is shown by the electrolysis survey, as readings taken along this street between the high-pressure hydrants and domestic water pipes show these positive to the rails. As a matter of fact, this condition is met throughout the whole centre of the city, and it can therefore be stated that electrolysis is taking place in the whole of this district.

Referring to the return feeders, Prof. Herdt states that the tracks are bonded at the corner of Main Street to return feeders of a total sectional area equal to 6,848,000 circular mills. The drop of potential between this point and the negative 'bus-bars, if these carried the whole railway current, would reach 12 volts at times. The distance is approximately 1,200 ft., that is, the drop of potential from these tracks to the station is one volt per 100 ft. This is, he says, altogether excessive, a drop of one-half volt per 300 ft. is usually considered large enough. Return feeders, besides the one stated above, are also used; they are bonded to the tracks at different points of the system, but they are of comparatively small section, and little current can be carried by them.

As a remedy for the troubles, Prof. Herdt recommends, first, the installation of sub-stations at different points of the system with a view to diminishing the amount of current to be returned through the rails in the centre of the city; secondly, Proper rebonding of all tracks that show defect; thirdly, Special bonding and cross bonding work at intersections; and, fourthly, A system of inspection of track returns by the railway company. In addition, he says, the current density in the rail returns must be kept low. The soil in the city shows a very low resistance and only a very small difference of potential in rail returns can be allowed. This must be effected by a rebonding of the tracks which indicate excessive drop. All bonds whose resistance is greater than 4.5 feet of rail should receive attention. Track intersections should also receive careful attention, and ground plates at sides of bridges to carry return currents from one side of the river bank to the other must be done away with and insulated feeders placed instead.

The Winnipeg Electric Railway Company is already carrying out work along these lines, following recommendations made by W. B. Boyd, chief engineer of the Toronto Railway Co. and Toronto Power Co., and approved by Prof. Herdt. The company has also placed orders for electrical machinery, which will be installed in three new sub-stations, and this will reduce very largely the amount of current returning through the rails on Main Street. In connection with the rebonding of the tracks, the company have now in the city, and in operation, a bonding car for electrically brazing copper bonds on the rail joints. This type of bond, carefully installed, will secure an effective system of rail return. It can be easily applied on old work with very little disturbance of pavements. Besides the above, the company are renewing the rails in several streets.

Concluding, Prof. Herdt says that the company must be instructed to proceed with this rebonding work and with the installation of the sub-stations without delay. The rebonding of the tracks must proceed night and day, until the whole system is in proper condition. After this is done, all bonding of the rails to the telephone cables and pipes should be removed, as well as the ground plates at bridges. The section of the return feeder from Main Street corner must also be increased. The track returns should be under test at all times, in order to remedy at once any faulty bonds as they appear. Accurate records of the drop of potential at different points of the railway system should be kept by the railway company and be open to the inspection of the city electrician. If the above recommendations are carried out with a desire to obtain best results, troubles due to electrolysis will be practically eliminated. Accompanying the report are some photographs illustrating some very bad cases of electrolysis. Among these are a water main with a hole right through it, and a cable with the lead sheath quite eaten away in two places, both dug up in Winnipeg.

Post Office Underground Wires.—The *Times* states that the Postmaster-General has decided to proceed at once with the work of placing the Post Office telegraph wires underground between Chatham and Dover. The contracts have been given out in sections, so that the operations may be carried through expeditiously. The telegraph wires between Chatham and London are already underground and working very satisfactorily.

Opening of the Tramways over Blackfriars Bridge.—An article on the electrical work done in connection with the widening of Blackfriars Bridge, and the completion of the tramways over it, appears on page 809. After the Lord Mayor had performed the ceremony of declaring the bridge open on Tuesday, a decorated car, driven by Mr. A. L. C. Fell, Chief Officer of the L.C.C. tramways, drove from the Embankment to a pavilion at the north-western corner of the bridge, and Sir Melvill Beachcroft, Chairman of the L.C.C., stepped out, and formally asked the Lord Mayor's permission for the L.C.C. tramcars to pass over the newly-widened bridge. The Lord Mayor said this was one of those requests which were granted before they were made, and shook Sir Melvill Beachcroft by the hand to typify the union of the two great municipal bodies. This completed the inaugural ceremony.

Lifts at the Strand Palace Hotel.—This new hotel is fitted with a very complete system of lifts by Messrs. R. Waygood & Co., Ltd. There are two main passenger lifts, each capable of carrying a load of 10 cwts., or seven persons, at a speed of 300 ft. per minute. One of these lifts is worked by hydraulic power from the high-pressure main of the London Hydraulic Power Co., and the other one by electric power, the latter being arranged with winding gear, controlled electrically by a switch in the cage. Electrical indicators, showing the position of each lift at every floor by means of an electric lamp, are also fitted. The cages are provided with special safety apparatus to prevent the descent of the cage in case of the suspension ropes failing, and safety appliances to guard against over travel in either direction. There are two goods lifts travelling up through the building, one operated by hydraulic power, and capable of carrying loads of 15 and 20 cwts., and one direct-acting platform lift from the basement to the ground floor. There is also a very complete installation of electric service lifts—15 in number—serving the various floors and operated by push-button control with automatic stopping at each end of the travel.

LOCAL NOTES

ACCRINGTON: *Electrical Exhibition.*—The Electrical Exhibition which had been held by the Corporation, closed last week. There were 16,500 visitors, and the receipts amounted to £140.

AMBLE: *Street Lighting.*—As a result of a popular vote, 251 persons have voted in favour of electric street lighting and 129 against. 1,014 papers were sent out. A resolution has been passed by the Council to consult an expert, and to take a second vote of the people.

BATH: *Loan Sanctioned.*—The Local Government Board have sanctioned the loan inquired into for last June, made up as follows:—£1,775 in respect of the expenditure on the undertaking up to March 31st, 1909; £775 for new works at the generating station; £4,000 for expenditure on mains from April 1st, 1909; £1,500 for expenditure on services from April 1st, 1909; £500 for expenditure on transformers from April 1st, 1909; £140 to defray expenditure already incurred on meters since April 1st, 1909.

BETHNAL GREEN: *Electricity Supply.*—A special meeting of the Council is to be convened for the 30th inst., to consider in committee the matter of the supply of electricity in the borough. Quotations have been sent in from adjoining authorities and companies, and it was recommended by the committee that negotiations be opened up with Hackney, but this recommendation was not agreed to by the Council, at their meeting on July 15th.

FRINTON: *New Generating Plant.*—Extensions have been completed at the works of the Frinton Electric Light & Power Co., including a new 150-kw. dynamo, driven by a vertical four-cylinder Hindley gas engine supply from a "Mersey" producer. The generator, which was supplied by the Electrical Co., is fitted with slip rings, and a "compensator," or balancing transformer for the three-wire system. Tests have given a consumption of 0·87 lb. of anthracite per b.h.p.-hour. The consulting engineers were Messrs. Preece and Cardew.

LECHLADE: *Street Lighting.*—The Council have accepted the tender of the electric lighting company for lighting the streets electrically. Oil lamps have been in use hitherto.

LONDON: *L.C.C. Hampstead Tramways.*—Col. Yorke made a Board of Trade inspection of the final portion of the L.C.C. electrified lines from Holborn to Hampstead last week, and the cars commenced running on Friday.

Stoke Newington.—The approval of the Hackney Borough Council has been given to the proposed installation by the London County Council of automatic electric signals at each end of the single track section in High Street, between Brooke Road and Church Street.

MEXICO: *Shipping Facilities.*—It is announced that the disability of not being able to consign on through bill of lading to interior points in the Republic has been removed, and these documents can now be obtained from all the steamship companies serving Mexican ports. Information regarding this and other matters relating to Mexico will be gladly given on application to Mr. E. J. Bray, the General European Agent of the National Railways of Mexico, at Dashwood House, 9 New Broad Street, London, E.C.

NEWCASTLE (IRELAND).—Messrs. J. W. Fraser & Co., of Lewisham, have given notice that they are applying to the Board of Trade for a Provisional Order, authorising them to generate and sell electricity for lighting and power purposes within the Newcastle Urban District Council's area.

NEWCASTLE-UPON-TYNE: *Tramways.*—The annual report states that 60¼ miles of single track are now worked by the Corporation. Considerable economy has been effected at the power station, due to the employment of batteries and boosters, and 2,417 tons less coal have been used during the year for practically the same output (about 10 million units). The revenue shows some decrease, owing to the recent strikes. The gross receipts were £269,541, and the working costs, exclusive of street lighting, amounted to £121,076.

NEWPORT (Mon.): *Street Lighting.*—The street gas lamps in Coverack Road and the portion of Prince Street where cables are laid are to be converted for electric lighting.

PARIS: *Electrification of Suburban Railways.*—A scheme is being taken in hand for the electrification of an extensive section of the suburban lines. A commencement is to be made from the St. Lazare station on the lines to Argenteuil and St. Germain-en-Laye. Continuous current at 600 volts supplied from sub-stations is to be employed. It is stated that the whole scheme involves about 21 miles of line, and that the total cost of conversion will amount to over two million pounds.

PUDSEY: *Tramcar Accident.*—The brakes of a tramcar making the journey from Pudsey and Leeds, on Wednesday of last week, failed to act when the car was descending a steep hill. The car left the rails on a sharp curve in Pudsey, ran down the main street at a very high speed, and mounted the pavement on one side of the street, demolishing two shop fronts. The driver suffered only very slight injuries, but two passengers were more seriously hurt.

ROSYTH: *Power Station at the Naval Base Works.*—Messrs. Easton, Gibb & Son, the contractors for the naval base works, are about to erect a private power station for the supply of electric power and light throughout the works. Four National gas engines with suction-gas plants, using gas coke fuel, and aggregating 1,100 b.h.p., are to be erected. Current will be distributed at 500 volts to the various motors for work, including quarrying, stone crushing, concrete mixing, the driving of machine shops and saw-mills, and pumping.

SOUTH SHIELDS: *Electricity Accounts.*—The annual report records the sale of 3,127,059 units, an increase of 172,049 over the previous year. The revenue was £25,559, and the working expenses were £13,093. After meeting capital charges, &c., the final surplus is £1,209.

WATFORD: *Tramways.*—The Urban District Council are to call the attention of the Herts County Council to an offer made by the latter body in July, 1903, to take electricity from the Urban District Council for the working of the proposed tramways at Watford at a price to be agreed upon, or in default of agreement the price to be fixed by the Board of Trade. It was mentioned at the meeting of the Urban District Council that the County Council are now about to obtain tenders for the construction of the tramways. The Urban District Council have instructed their engineer to ascertain the names of owners and occupiers outside the area who desire a supply of electricity. It was mentioned that application had been received for the lighting of Lord Essex's property.

WEDNESBURY: *Electricity Accounts.*—The annual report and accounts for the year ended March 31st, 1909, record a sale of 225,700 units, and a maximum demand of 150 kw. The units generated were 195,000, and 148,000 units were purchased. The total working expenses were £1,648, and the receipts £2,086. After the meeting of capital charges, &c., a balance of £184 was carried forward as against £195 last year. A contribution of £713 was received from the District Fund.

WHITEFIELD: *Transference of Order to Power Company.*—The Electric Lighting Order of the Council has been transferred to the Lancashire Electric Power Co., and the whole expense in connection therewith has been refunded by the company. It was remarked at a meeting of the Council that the transaction had coincided with a reduction in the price of gas in the district.

WILLESDEN: *Opposition to Tramway Scheme.*—The Willesden District Council have decided to oppose the London County Council and Middlesex County Council joint scheme for a tramway from the Marble Arch to Cricklewood unless the road is widened to 60 ft. through Kilburn.

WOLVERHAMPTON: *Tramway Extension.*—The new line from Queen Square to Stubbs Road, Pennfields, which, like the rest of the Wolverhampton tramways, is equipped on the Lorain surface-contact system, is ready for traffic, and a trial trip was run last week. The Board of Trade inspection was held yesterday.

WORCESTER: *Street Lighting.*—The Council have approved of an arrangement with the Electricity Committee whereby for £250 the Committee would instal 12 arc lamps and 57 Osram lamps in certain streets, aggregating 15,530 c.p., in place of 78 gas lamps and three small lamps, aggregating 3,000 to 3,500 c.p., costing £229 4s. 6d. per annum.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BRAY.—The sanction of the Local Government Board is to be asked for the substitution of a Diesel oil engine plant for the gas plant in the original scheme, for which a loan of £1,000 was recently granted. Tenders will be invited for a 50 b.h.p. Diesel engine, and also for some high and low tension disconnecting boxes, &c., which are required.

CALCUTTA. According to *The Board of Trade Journal*, the Calcutta Electric Supply Corporation, Ltd., are increasing their capital to the extent of £400,000, with the object of providing for the further extensions of mains necessary to meet the constantly increasing demands for current, and for the purpose of purchasing a site and erecting thereon and equipping a high-tension generating station.

SWANSEA.—Tenders are invited for the erection of an electric power station on the eastern side of the Prince of Wales Dock Lock. Particulars from Mr. A. O. Schenk, Harbour Offices, Swansea. Tenders by Sept. 23rd.

Miscellaneous

AUSTRALIA.—Tenders are invited by the Commonwealth of Australia for the supply and delivery at the Departmental Stores, Melbourne, of 100,000 porcelain insulators. Tenders, endorsed "Tender for 100,000 Porcelain Insulators," should be

Digitized by Google

addressed to the Deputy Postmaster-General, Melbourne, by whom they will be received up to 3 p.m. on 9th November.

The following tenders for telephone apparatus are also invited by the Australian Postmaster-General's Department:—*New South Wales:* October 6th, 2,550 common battery telephones; November 10th, branching metallic multiple magneto switchboard at Petersham telephone exchange; January 12th, 1910, common battery switchboard at North Sydney telephone exchange, and apparatus for use on subscriber's premises, North Sydney.

Queensland.—November 10th, Stores Branch, Brisbane, material for common battery switchboard; September 21st, two tons sulphate magnesia, 7,000 porous pots, Leclanche, 10,000 zincs, 60 miles tinned copper wire, rubber insulated, taped and braided, 30 miles single bridle wire, 20 tons iron galvanised wire, 3 tons galvanised stranded steel wire, 2 tons hard-drawn copper braided wire.

NEW SOUTH WALES.—Tenders are invited by the Public Works Department by September 20th for electrical machinery for operating swing span, Parramatta River swing bridge.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the ***whole building.***

LONDON.

N.W.—Parish Hall, Flower Lane, Mill Hill, Hendon (£2,300), for the Churchwardens of the Parish Church.

W.—Electric theatre on site of No. 24 Tottenham Court Road, W., for Living Picture Co., 15 Britannia Street, W.C.

Police section house, Beak Street, W. (£10,000). Surveyor, J. Dixon Butler, New Scotland Yard, S.W.

Italian hotel and restaurant. Builders, Watson & Co., 10 Glasshouse Street, Regent Street, W.

Skating rink, Hammersmith, W. Roller Rink Construction Co., 6 Cherry Street, Birmingham.

W.C.—Skating rink, Shaftesbury Avenue, W.C. Roller Rink Constructon Co., 6 Cherry Street, Birmingham.

Buildings, corner of Holborn and Featherstone Buildings. Builder, J. Waddington, 59A Carter Lane, St. Paul's, E.C.

Extensive buildings, Shaftesbury Avenue, W.C. Builders, J. Parkinson & Son, Ltd., Blackpool.

Central premises, Tottenham Court Road, W.C., for the Y.M.C.A. (£175,000). Architect, Rowland Plumbe, 13 Fitzroy Square, W. Builder, John Greenwood, Ltd., 12 and 14 Arthur Street West, London Bridge, S.E.

PROVINCES.

BARROWFORD.—Additions to St. Peter's and St. Paul's Church. The Trustees.

BARTON.—Premises for Stamford Banking Co. Architect, A. Stamp, Barton-on-Humber.

BISHOP AUCKLAND.—Rink. Olympia Rink Co., Ltd., Bishop Auckland.

BISHOPS STORTFORD.—Extensions to infirmary. The Guardians.

BLACKPOOL.—Street of houses. Surveyor, St. John's Estate Co., Blackpool.

BOURNEMOUTH.—Skating rink. Architect, G. F. Ward, 71 Colmore Row, Birmingham.

BOTHWELL.—Roman Catholic Chapel (£8,000). The Trustees.

CHESTERFIELD.—Additions to workhouse. The Guardians.

DARLINGTON.—Banking premises, London & Joint Stock Bank. Architects, Clark & Moscrop, Darlington.

DENTON.—School (£5,000). Builders, J. Baker & Son, Stroud.

DERBY.—Alterations to Union Workhouse (£439). Architect, F. C. Coulthurst, 4 Albert Street, Derby.

DUDLEY.—Storage battery house and generating station, Stourbridge Road, for the Corporation.

Additions to Training College, Castle View, for the Dudley Education Committee.

DURHAM.—School, Close House. Architect, W. Rushworth, Shire Hall, Durham.

GRIMSBY.—Adaptation, Spring Church Buildings, for offices for Borough Engineer and Treasurer. Surveyor, H. G. Whyatt, Grimsby Town Council.

LIVERPOOL.—Additions to Southern Hospital (£5,000). Builders, Jones & Son, Heasant Street, Liverpool.

LONDONDERRY.—Music Hall, Strand Road. Architect, J. Mulholland.

PLYMOUTH.—The lighting of the new Museum and Art Gallery is to be carried out in accordance with an amended scheme, which will involve an estimated expenditure of £417, the sum provided for in the contract being £250. At present, however, fittings are to be provided for the Central Hall, and the first floor art galleries only, at an estimated cost for wiring and fittings of £278. Electricity is to be substituted for gas in the Corporation laboratory.

PONTYPOOL.—Additions, reformatory. Architect, W. H. D. Caple, Church Street, Cardiff.

PORT SUNLIGHT.—Institute (£1,000). Builders, Ford & Son, Birkenhead.

RADCLIFFE.—United Methodist Church (£2,527). Architects, J. D. & S. J. Mould, Walmersley Road, Bury. Builder, F. W. Porter, Bury.

RYDE (ISLE OF WIGHT).—St. John's Parish Hall, Oakfield. Architect, G. Broughton, Ryde.

STRETFORD (MANCHESTER).—Alterations, &c., to Talbot House Schools, for the Royal Schools for the Deaf and Dumb.

WALSALL.—Baptist Church, Midland Road, for the Trustees.

WALLSEND.—Parish Hall. Frank Caws, Steel and Caws, Sunderland.

WELSHPOOL.—Hospital. G. Snook, Borough Surveyor, Welshpool.

WINTON.—Schools (£14,000). Architect, F. W. Lacey, Municipal Buildings, Bournemouth. Builders, J. and M. Patrick, Wandsworth, S.W.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—Tenders of Messrs. Johnson & Phillips, Ltd., of Charlton, for telegraph material, &c., to the amount of £983 have been accepted by the Australian Postmaster-General.

BRISTOL.—The Electricity Committee have accepted the tenders of the Electrical Co. for a year's supply of A.C. meters, of the General Electric Co. for a year's supply of carbons, and of Messrs. Siemens Brothers' Dynamo Works for a supply of arc lamp globes.

BURSLEM.—The acceptance of a tender for a Belliss-Siemens generator, &c., is recommended by the Committee.

HOWRAH.—The D.P. Battery Co. have received an order for the supply and erection at Howrah of a storage battery having a capacity of 800 kw. hours, for the East Indian Railway Co., and another for New South Wales.

PLYMOUTH.—The Town Council has accepted the tender of the National Telephone Co., Ltd., for connecting the residences of firemen in the vicinity of Vinegar Hill with the Central Station by means of electric bells, at £12 per annum for three years.

SWANSEA.—The Electric Lighting Committee have accepted the following tenders:—Arc lamps, Veritys, Ltd.; cables, Callender's Cable & Construction Co.; arc lamp pillars, brackets, raising and lowering gear, the London Electric Firm, from £352 11s. 8d. to £385 19s. 8d., according to the type of raising gear best suited for use in conjunction with the arc lamps recommended; switch pillars and joint boxes, Lucy & Co., Ltd.

WORTHING.—The tender of the Beck Flame Lamp Company for the supply of Beck flame lamps to replace the present arc lamps, at a cost of £638, has been accepted.

APPOINTMENTS AND PERSONAL NOTES

Mr. P. F. Allan, of the Clyde Valley Electric Power Co., was married on Saturday last at Dulwich to Miss Edith M. Barrow, daughter of J. G. Barrow, Esq. (Retired Fleet Engineer, R.N.).

Mr. W. B. Morgan, station superintendent at the Avonbank station of the Bristol Corporation, has resigned on obtaining an appointment at Dawson City.

The Bristol Electricity Committee recommend the promotion of Mr. A. E. Wilson, distribution superintendent, to the post of deputy electrical engineer, at a salary of £300, rising to £400 per annum, to succeed Mr. Couzens, who is now borough electrical engineer at West Ham.

Mr. W. P. Durtnall has been awarded the Denny Gold Medal of the Institute of Marine Engineers for his Paper on "The Generation and Electrical Transmission of Power for Main Marine Propulsion and Speed Regulation," read July 18th, 1908, at the meeting of the Institute at the Franco-British Exhibition.

Mr. W. Buchanan, who has been for some years designer and chief engineer to the Electric Construction Co., of Wolverhampton, has been appointed lecturer at Faraday House on electrotechnics and the design of electrical machinery.

Naval Electrical Contracts.—In the House of Commons yesterday the First Lord of the Admiralty was asked by Mr. Renwick, member for Newcastle-on-Tyne, whether, in the case of contracts placed for the electric light installations in British warships now building, the contractors being British branches of German firms, it was made a condition of the contract that only British-made cables, machinery, and fittings should be used, and only British subjects employed in the superintendence and fitting on board the vessels; and whether precautions had been taken to prevent the plans supplied to the contractors being sent abroad or shown to foreigners. Mr. McKenna replied that it was made a condition that only British-made cables, machinery, and fittings shall be used, and only British subjects employed in the superintendence and fitting of them on board the ships. Further, a provision had been embodied in recent contracts binding the contractors to secrecy, in accordance with the Official Secrets Act, 1889.

Digitized by Google

MISCELLANEOUS CITY NOTES

URBAN ELECTRIC SUPPLY CO.—A dividend of 2s. 6d. per share has been recommended.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—In order to provide for extensions, the directors have decided to make an issue of £500,000 of fresh capital, divided as follows:—200,000 5 per cent. £1 cumulative perpetual preference shares, at a premium of 1s.; 200,000 5 per cent. £1 non-cumulative preferred ordinary shares, at a premium of 2s.; 100,000 deferred ordinary shares of £1 each, at a premium of 3s.

BROMLEY (KENT) ELECTRIC LIGHT AND POWER CO.—An interim dividend at the rate of 4 per cent. per annum has been declared on the ordinary shares payable October 1st.

SOUTH METROPOLITAN ELECTRIC LIGHT AND POWER CO.—The debenture stock register and register of transfers will be closed from September 17th to 30th, 1909 (both days inclusive), for preparation of warrants for interest at the rate of 4½ per cent. per annum, payable October 1st, 1909, for the half year ended that date.

SHAWINIGAN WATER & POWER CO.—A dividend of 1 per cent. for the quarter ending 30th inst. has been declared.

WINNIPEG ELECTRIC RAILWAY CO.—A dividend of 2½ per cent. has been declared for the quarter ending 30th inst.

COMPANIES' MEETINGS AND REPORTS

YORKSHIRE ELECTRIC POWER CO.—According to the half-yearly report, the receipts for the six months ended June 30th were £11,169, as against £8,698 for the previous corresponding half-year. The net profit amounts to £1,069, as compared with £363 in 1908, and a loss of £1,211 in 1907. A steady increase in supply is recorded, notwithstanding adverse conditions of trade in the district, and further generating plant will shortly be required. The whole of the issue of £45,000 second mortgages have been allotted. Mr. W. G. Jackson has been elected to the board.

BRITISH THOMSON-HOUSTON CO.—At the ordinary general meeting held on Tuesday, Mr. George Franklin presiding, the report—an abstract of which was given on page 804 of our last issue—was adopted. The chairman stated that a number of improvements and additions had been made to the plant at Rugby, and that during the year the company had sold Curtis turbines aggregating 15,000 kw. In spite of the fact that the depression of trade had considerably hindered various industrial developments, a large number of important contracts had been secured, and satisfactory progress had been made in the development of metal filament lamps.

NEW COMPANIES

E. M. F.—Registered on August 24th, with a capital of £20,000 in £1 shares, to adopt an agreement with J. M. Bein, A. J. Grose, T. H. Satchwell, and O. H. Bishop, and to carry on the business of electricians, mechanical, and electrical engineers, suppliers of electricity for light, heat, motive power, or other purposes, &c.; The subscribers are:—J. M. Bein, 103 Muswell Avenue, Muswell Hill, N., electrical engineer; A. J. Grose, 14 Ashchurch Grove, Shepherd's Bush, W., gentleman; O. H. Bishop, 7 Layer Gardens, West Acton, W., electrical engineer. The first directors are J. M. Bein, A. J. Grose, and O. H. Bishop. Remuneration of J. M. Bein and A. J Grose, £450 each per annum; of O. H. Bishop, £500 per annum. Registered by Barfield & Barfield, 47 Finsbury Square, E.C.

MIDLAND ELECTRIC WIRE CO.—Registered on August 14th, with a capital of £5,000, to acquire the business carried on as the Midland Electric Wire Co., and to carry on the business of electric cable and insulated wire manufacturers and dealers, electricians, engineers, &c. W. J. Levi, 154 Fosse Road, South Leicester, is manager. Registered by Rawle, Johnstone & Co., 1 Bedford Row, W.C.

PLUTTE, SCHEELE & CO.—Registered on Sept. 3rd, with a capital of £6,000, to adopt an agreement with F. Plutte for the acquisition of the business of Plutte, Scheele & Co., and to carry on the business of manufacturers and sellers of articles and accessories required in the electrical and allied trades, &c. Registered office: 18 and 19 Queenhithe, E.C.

Telephone Station on Monte Rosa.—The Geneva correspondent of the *Times* states that the telephone line to the Margherita Observatory, near the summit of Monte Rosa, 15,000 feet above the sea level, has just been completed. This will enable the observatory, which, together with the telephone line, has been built at the expense of Queen Margherita of Italy, to communicate with Milan and Rome.

Electrical Marine Propulsion.—Mr. W. P. Durtnall has called our attention to a slight error in the report of Mr. J. McLaren's Paper on the uses of electricity on board ship, which appeared in our issue of last week. The voltage of the 10-cycle generator of the electric driving gear for a dredger, which was referred to as being 350 volts, should be only 74 volts, the full pressure of 350 volts being given by the 60-cycle machine. The intermediate machines deliver current at 134, 182, 239, and 295 volts respectively. The current delivered to the motors will be approximately the same in each case.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 10s. to £60 per ton (last week, £60 5s. to £60 15s.).

HIGH-SPEED TURBINES.—Messrs. Willans & Robinson, Ltd., after prolonged experiments, are placing on the market a steam turbine of the impulse type, intended to meet those cases in which a speed of as high as 3,000 r.p.m. is admissible. This will provide for a capacity up to 1,500 kw. The turbine has been designed with a view to efficiency, as well as simplicity. The rotating element consists of two wheels only, but the economy realised, we are informed, compares favourably with that of any other turbine. In future, therefore, Messrs. Willans & Robinson, Ltd., will be in a position to supply either turbines of the Parsons' or of the impulse type, and will be glad to put forward the type most suitable for the conditions to be met.

THE "EDISWAN" CO.—The Edison & Swan United Electric Light Co., Ltd., has informed us that Mr. William Murray, of the firm of Williamson, Murray & Co., has joined the board of the company.

THE ELECTRICAL LEAGUE.—The address of the Electrical League has been changed to Bank Buildings, Kingsway, W.C.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Official Receiver's report regarding the winding up of the Uxbridge & District Electric Supply Co. last June has been issued. It appears that the liquidation accounts show assets valued at £75,038, to meet debenture claims and interest £52,579, and unsecured liabilities £6,622. There is disclosed a surplus of £15,748 in assets, after discharging the liabilities, but a loss of £10,526 as regards shareholders. The failure is attributed by the directors to want of working capital, and to loss of business caused by the closing down of customers' works.

The first meeting in the bankruptcy of J. H. Burdett, Electrical Engineer and Contractor, of Rugby and Coventry, will be held at 8 High Street, Coventry, at 3.15 p.m., on the 20th inst. The public examination will be on October 11th.

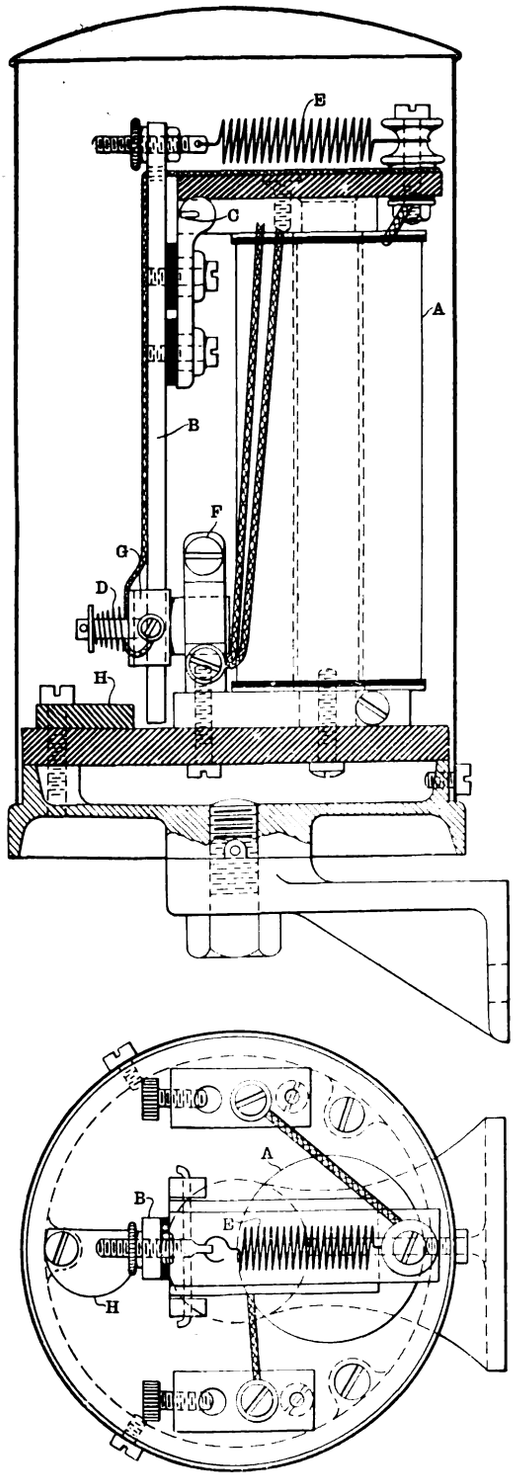
A meeting of the Poole & District Electric Traction Co. will be held at the Electrical Federation Offices, Kingsway, on October 11th, at 2.30 p.m., to hear the account of the winding-up.

A receiving order has been made against J. E. Fenwick, plumber and electrical engineer, of Durham.

The application for the discharge of A. H. Pigott, electrical engineer, of London, trading with J. G. E. Cunningham as Laing, Wharton, & Cunningham, will be heard on October 13th.

UNE Grande COMPAGNIE FRANÇAISE *construisant le Matériel Electrique en général* et bien placée pour lutter avantageusement avec la concurrence, désire s'entendre avec une Maison d'installations établie, ayant un mouvement d'affaires important, les capitaux et le personnel technique nécessaires, pour agir en son nom, comme acheteur privilégié bénéficiant des conditions spéciales d'exportation, avec le monopole de vente pour le Royaume-Uni d'Angleterre. BOX A81, ELECTRICAL ENGINEERING, 203, Temple Chambers, London, E.C.

JANDUS ARC LAMPS AND ACCESSORIES



IT is now over eighteen months ago that the enclosed flame arc lamp, known as the Jandus regenerative lamp, was put upon the market, and although the lamp in its present form differs little from that described at the time (ELECTRICAL ENGINEERING, February 27th, 1908, Vol. III., p. 299), the following improvements in detail are of interest.

It will be remembered that the feature of the lamp is that circulation of the hot gases is provided for by means of two metal tubes, which connect the upper and lower ends of the small inner globe, causing the vapourised chemicals to pass several times through the arc before they are finally deposited on the cool interior surfaces of the tubes. In the original form the upper carbon was a plain, soft-cored one, while the lower carbon was star-shaped in section, the grooves being filled with a paste of calcium fluoride, calcium tungstate, and sodium tungstate of potassium sulphate, mixed with a suitable binder. It has been found that the upper carbon occasionally burned down to an inverted cup-shaped tip, so that the arc would not strike well from the point of the lower carbon. By using an upper carbon with six soft cores spaced symmetrically about the centre, the tip is caused to burn to a point, which bears against the point of the lower carbon when the two are brought together and ensures the arc being struck. These soft cores are now composed of a mixture of carbon and a special chemical paste, as it has been found that the presence of chemicals in the upper carbon gives a fatter arc. Another re-

Digitized by Google

cent improvement is in the shape of the lower carbon, the ridges of which are provided with enlarged edges, so as to hold the paste more firmly in the grooves. A new holder for the lower carbon, comprising a short piece of brass tubing, split across two diameters, and surrounded by a collar with a tightening screw, has also been devised, in order to obtain a better contact than in the earlier pattern of holder.

The rocking lever, to which are attached the clutch lever and the plungers of the controlling magnets, is now mounted on phosphor bronze ball bearings, which gives a very free and easy movement, free from jerks. Abstracts of the patents covering this and the other features of the lamp have been mentioned from time to time in our "Patent Record." Among other improvements are that of providing the shunt coil with an armouring of steel wire, the use of aluminium caps with annular baffling ridges, instead of iron caps, and furnishing the upper cap with a wide ring which fits into the inner globe, and, by reducing the difference of temperature between the cap and the globe, prevents the breakage of the latter.

JANDUS SELF-REPLACING AUTOMATIC CUT-OUT FOR ARC LAMPS.

In the alternating-current lamp, a spring is interposed between the magnet plunger and the clutch lever, so that the inevitable vibrations shall not be transmitted to the carbon, and for the same reason, the magnet coil is cushioned between its supports by rubber rings. Aluminium is now being used for many parts which were previously of brass; the rockers are now of aluminium, as well as the caps.

It may be mentioned that there is now, at the works in Hartham Road, Holloway, sufficient plant (comprising grinding, sifting, and mixing machines, and four gas-heated baking ovens) to turn out 7,000 pairs of prepared carbons per week. The carbons are wrapped in paper and then dipped in paraffin wax before leaving the works, to keep them dry.

While gathering the above information at the works and offices (Hartham Works, Holloway), our representative was informed that a special low-voltage enclosed flame lamp is being experimented with, and will eventually be placed on the market. This will take about five amperes, at from 45 to 50 volts only, so that it will be possible to run two in series on a 100-volt circuit. Thus a lamp consuming only 250 watts or less may eventually be developed. The present Jandus regenerative lamp takes some 550 watts, with about 78 volts across its terminals.

Among the interesting machines at the works was one especially designed for winding resistance wire into a helix for placing on the porcelain bodies of the series and substitutional resistance units. The wound helix passes through a three-jaw chuck, which grips it over a fixed horizontal core wire, stretched along the bed of the machine. When rotated, the helix is formed along the fixed wire. When one length is completed, it is drawn through the chuck on to a bobbin at the other side, this being rotated sideways to prevent the twisting of the helix.

A new pattern of automatic cut-out for arc lamps has just been introduced by the firm. This device, which is illustrated in the accompanying figure, has a differentially-wound coil and a self-replacing mechanism. It is mounted in a water-tight copper case on a strong base, which swivels on a special bracket for attaching to the inside of the lamp-post base. A pattern adapted to be hung above the lamp can also be obtained. On the failure of the lamp from any cause, a substitutional resistance is switched in, in the usual way. It may happen, however, that a bent carbon or other cause may prevent the lamp feeding at the right moment, in which case the cut-out would act, but if vibration frees the lamp, the cut-out will switch the substitutional resistance out and the lamp in. The magnet coil *A* comprises two windings, the series winding being outside. The armature *B* is pivoted at *C*, and the two springs, *D* and *E*, render the mechanism independent of position and the influence of gravity. The spring *D* ensures a good contact, and the adjustment of *E* determines the pressure at which the armature is released. The pressure at which it is pulled up is adjusted by moving the cam *H*, which varies the distance between the armature and the magnet pole. The series coil holds the armature up when the shunt is short-circuited. The firm's patent non-arcing contacts are employed, comprising a fixed carbon stop, held in the grip terminal *F*, and a loose, box-shaped collar, *G*, round the armature. The collar is pressed by the spring *D* on to the carbon surface, whatever angle this assumes. If the carbon surface is not flat, it burns to a good contact, and a deposit of carbon collects on the silver collar. The device is very sensitive, and can be set to operate with a total pressure variation of three volts. In practice, however, it is usual to set a cut-out for a 45-volt lamp to cut-out at 60 volts and pull in again, re-inserting the lamp, at 35 volts. A somewhat narrower range can be used sometimes with advantage, but if the adjustment is too fine, the device chatters. The whole mechanism is mounted as shown on a non-hydroscopic insulating base.

The South Wales Institute of Engineers.—The next quarterly meeting of this Institute will be held in Cardiff on October 9th next, at 2.30 p.m. Among the Papers down for discussion is one by Mr. W. H. Patchell on "The Electrification of the Ferndale Collieries," and there will be a resumed discussion on a Paper by Mr. C. B. Chartres, on "The Utilisation of Exhaust Steam in Collieries," and on "French Coal Dust Experiments," by Mr. J. Taffanel, translated from the French by Mr. W. N. Atkinson.

Delay on the Bakerloo Tube.—Owing to the breaking away of a contact shoe from one of the motor-coaches of a train on the Baker Street & Waterloo Railway on Thursday morning last, there were delays of 10 and 20 minutes on the south- and north-going lines, respectively. The mishap took place at Westminster Bridge Road station, and the disabled train was pushed into the Elephant and Castle terminus by the following train.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 9th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

865/08. **Electrolytic Meters.** W. B. THORPE. In electrolytic meters of the type in which acidulated water is decomposed by the passage of the current into oxygen and hydrogen which are recombined after definite amounts have been evolved, inaccuracies have been caused by the gases leaking past the mercury column in the centre of the tube to the part beyond, and by air passing in the reverse direction, owing to differences of pressure. In the present construction, one or more rings of platinum are fused into the wall of the tube, and these make a gas-tight joint with the mercury column. Further, the mercury column is connected to the negative pole of a source of E.M.F. to prevent oxidation of the surface, and to avoid the evolution of gas at the surface, the column is electrically connected to the anode in the cell by a capillary thread of mercury offering a high resistance. An electromagnetic device for registering the successive explosions is also described in this specification. Eight claims, five figures.

17,283/08. **Compound Conductors.** R. K. GRAY. In a conductor composed of a central solid or stranded core of one metal surrounded by a wire or tape sheath of another metal, the wires or tape of the sheath are given a coating of the same metal as that at the surface of the inner core. The object is to prevent corrosion due to moisture. If more convenient, both core and sheath wires may be given a surface coating of the same metal. Four claims.

17,505/08. **Wireless Telegraphy.** G. MARCONI and MARCONI'S WIRELESS TELEGRAPH CO., LTD. This specification describes a transmitter consisting of two parallel discs rotating in opposite directions and having on them pegs or studs of copper between which the discharge takes place. Discs of 2 ft. diameter, having each two studs, and rotating at 3,000 r.p.m. are found to work well in practice. Two claims, one figure.

28,554/08. **Manufacture of Metal Filaments.** W. SCHÄFFER. Metal filaments produced by squirting a paste through a fine circular die are passed between a pair of rollers immediately after the squirting, while they are still plastic, so as to be flattened and given a rectangular cross-section. One claim.

1,673/09. **Lamp-holder.** T. BIRCHALL. The porcelain or wooden block into which are fixed the contact pins is loose in the metal casing of the holder, being pressed downwards on to an inner ridge by a spring contained in the cap. There are no spring contact plungers. The usual bayonet slots are provided, and the contact block is pressed against the lamp by the spring. Two holes are made in the casing above the block, and when a pin is put through them it is impossible to lift the block and insert a lamp. The shade is secured by the top ring, which may cover up the holes for the locking pin. Two claims, five figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BASTER and ENSER [Connection of wires] 17,735/08; WILDERMAN [Chlorine-resisting ebonite] 18,269/08.

Dynamos, Motors, and Transformers: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Machines] 18,053/08.

Electric Ignition: KIRBY [Detachable terminal for ignition wires] 26,420/08.

Electrometallurgy and Electrochemistry: RÖCHLING'SCHE EISEN- UND STAHLWERKE-GES. and RODENHAUSER [Induction furnaces] 18,513/08; BECKET [Galvanising rods and tubes] 24,467/08.

Incandescent Lamps: SIEMENS & HALSKE AKT.-GES. [Increasing ductility of tungsten] 17,611/08; ARSEM [Manufacture of lamps] 18,054/08; COOPER [Packing box] 241/09; KRÜGER [Regenerating blackened carbon-filament lamps] 8,283/09.

Storage Batteries: ACCUMULATOREN FABRIK AKT.-GES [Plates] 6,248/09.

Switchgear, Fuses, and Fittings: ALLGEMEINE ELEKTRICITÄTS GES. [Crane or lift controller] 17,536/08; NEWALL [Anti-vibration lamp pendant] 22,003/08; LODGE [Switches] 23,423/08; LUNDBERG [Switches] 7,993/09 and 8,429/09.

Telephony and Telegraphy: BENINGTON [Enumerating telephone calls] 23,623/08.

Traction: WHITELEY [Tramcar life-guard] 15,624/08; WILSON and CLAFLIN [Signalling] 17,858/08; CLOUD [Air brakes] 18,020/08; WARNER, WARNER ENGINEERING CO., and MOUNTAIN & GIBSON, LTD. [Axle-trucks] 22,211/08; BAYLEY [Trolley head] 25,758/08; SIEMENS BROS. DYNAMO WORKS, LTD., BROADHEAD, and HAWKINS [Electromagnetic control of train lighting] 4,425/09; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Signalling] 6,985/09.

Miscellaneous: VENNER [Illuminated signs] 25,715/07; SUNDERCOMBE [Flash-signal apparatus] 18,310/08; MARSHALL, FLEMING and ANDERSON [Electric cranes] 21,311/08; MACKINTOSH [Telemotor gear] 7,048/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electric Ignition: UNTERBERG & HELMLE [Distributor] 19,024/09.

Electrochemistry: SALTPETERSÄURE INDUSTRIE-GES. [Arc furnace for treatment of gases] 19,466/09.

Telephony: SIEMENS & HALSKE AKT.-GES. [Automatic substation switchboards] 16,928/09.

Miscellaneous: HUGUENIN [Magnetic pulleys and belts] 19,527/09.

Expiring and Expired Patents

The following Patents expire during the current week after a life of fourteen years:—

17,328 of September 17th, 1895. **Electric Piano.** G. H. DAVIS. The perforated sheet passes over a metal roller, and spring fingers make contact with the roller through the perforations. Electromagnets energised by this means cause swinging arms to come in contact with a rotating roller, and the movement conveyed to the arms by this roller is transferred to vertical rods, which in turn work on the piano keys.

17,660 of September 21st, 1895. **Dyes.** B. WILLCOX (*Badische Anilin und Sodafabrik*). Manufacture of dyes by the electrolytic oxidation of hydroxy carboxylic acids.

17,745 of September 23rd, 1895. **Soluble Anodes for Electrolytic and Primary Cells.** H. H. LAKE (*C. Hoepfner*). This patent is for soluble anodes, and is described particularly in connection with the electro-deposition of zinc using a lead anode. The lead is dissolved during the process, but is afterwards recovered from the anode liquid. Iron, nickel, manganese, the alkaline, and other metals may be obtained by this process, a salt solution of the metal being used as the cathode liquid.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Insulating Materials, &c.: CALLENDER'S CABLE & CONSTR. CO., and G. BARNARD [Insulating tape] 11,142/05.

Dynamos, &c.: H. H. LAKE (*General Electric Co., U.S.A.*) [Commutator] 11,832/02; O. T. BLÁTHY [Alternator field-pole windings] 11,840/03; SIEMENS BROS. & CO., F. HIRD, and A. T. BARTLETT [Synchronous running of D.-C. motors] 11,846/03; H. WRIGHT [Train-lighting dynamo] 11,842/04; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [A.-C. flywheel motor set] 10,895/05; C. W. SPEIRS and J. FRITH [Compressed-air brush-holders] 11,061/05; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Boosting-transformers] 11,074/05.

Electric Ignition: F. R. SIMMS [Driving magneto] 12,954/97; J. and G. KEITH [Ignition of gas lamps] 11,644/02; H. H. LAKE ("*Rapid*" *Elektrogasfernzünder-Werke*) [Control of gas lamps] 10,685/05; DRESDNER GASMOTOREN-FABRIK VORM MORITZ HILLE [Contact breakers] 25,502/05.

Electrometallurgy and Electrochemistry: M. OTTO [Ozoniser] 12,193/03.

Heating and Cooking: ELECTRIC EQUIPMENT & SECURITIES, LTD., and C. RUZICKA [Resistance units for radiators] 11,146/05.

Instruments and Meters: E. A. CAROLAN (*General Electric Co., U.S.A.*) [Power-factor indicator] 11,726/03; H. HERTZBERG, W. SNYDER, J. GRIFFIN, and H. BERNARD [Combined ammeter, voltmeter, and wattmeter] 10,959/05.

Switchgear, &c.: CALLENDER'S CABLE & CONSTR. CO. and J. C. WARD [Switch-fuse] 10,669/05; L. K. JOB [Thermal flashing switches] 10,707/05; W. H. ISHERWOOD [Switch] 10,910/05; H. J. READ [Cut-outs] 11,120/05.

Telephony and Telegraphy: H. H. LAKE (*Elektrisk Bureau*) [Self-restoring switchboard indicators] 11,738/03; E. DUCRETET [Telegraphic tape receiver] 10,629/05; W. P. THOMPSON (*Ges. für Drahtlose Telegraphie*) [Wireless telegraphy] 10,708-9-10/05.

Traction: H. H. LAKE (*Hall Signal Co., U.S.A.*) [Automatic signalling mechanisms] 10,616/01; H. H. LAKE (*E. Cantono*) [Trolley pole] 12,174/03; A. M. BULLARD [Signalling] 11,835/04; G. M. GIBSON and M. B. MOUNTAIN [Axle-trucks] 10,671/05; M. CUMMINS [Brakes] 10,747/05; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Pneumatic multiple unit control] 10,893/05.

Miscellaneous: H. H. LEIGH (*F. J. Sprague*) [Push-button lift control] 12,016/98; W. H. BAKER and F. E. KIPP [Stopping looms electrically on breakage of thread] 10,892/99; J. GARDNER [Control of mechanism by Hertzian waves] 10,589/01; W. H. CHAPMAN [Discharging electricity from paper on presses] 10,694-5-6/05; D. CARNEGIE [Air-pressure alarms] 10,739/05; L. B. WOODWORTH [Mines signalling system] 10,793-4/05.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** *weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

The Welsbach Incandescent Light Co. are advertising "Welsbach-Auer" metal filament lamps, in spite of the fact that the original Welsbach-Auer tungsten lamp patents are owned in this country by the General Electric Co., who make the Osram lamp. The Welsbach Co. are, moreover, offering to replace the whole of the carbon filament lamps of any installation with their metal filament lamps, and accept as payment the sum saved by the consumer on his quarterly electric light bill. (Page 828.)

We are able to give a short description of the leading features of the new design of impulse steam turbine which Messrs. Willans and Robinson are now making, in addition to the well-known Willans-Parsons turbine. (Page 829.)

In view of the uneasiness felt by the miners in some districts on account of the suggestion that the explosion in the West Stanley pit was electrically ignited, and of other recent accidents, we urge that a representative of the Miners' Federation of Great Britain and also of the Coal Owners' Association should be nominated to the Select Committee which is to revise the Special Rules.—The correspondence on the subject of the revision of these rules and of electrical work in mines generally is continued. The majority of our correspondents favour the use of armoured cable bonded throughout, and are emphatic on the necessity of placing the electrical plant in charge of skilled attendants. Almost all our correspondents are practical workers in mines, and give interesting information as to the conditions there. (Page 331.)

Among the specifications published by the Patent Office on Thursday last was one by R. F. Venner for an advertising sign, comprising letters outlined in transparent beads. A modification of the method devised by Messrs. Siemens & Halske for increasing the ductility of tungsten by adding nickel, consists in adding a small quantity of another metal. W. C. Arsem claims to obviate the blackening of metal-filament lamps by coating the glass stem with silver which absorbs any mercury vapour remaining in the bulb. A special construction of induction furnace is described by the Röchling'sche Eisen- und Stahlwerke Ges. and W. Rodenhauser, and a gear of the "free barrel" type for electric cranes, which prevents the slight fall of the load before hoisting, is protected by

Digitized by Google

J. Marshall and others. Ebonite-covered lugs and ebonite feet for accumulator plates are the subject of a specification by the Accumulatoren-Fabrik Akt.-Ges. The grant of a patent to S. Marietti for a method of fusing metal-filaments to their supports is opposed. W. Claypoole has surrendered his patent for an insulating material, probably as the result of the application which was made for its revocation. (Page 834.)

WE are now able to publish some further papers read at the meeting of the British Association at Winnipeg, and a report of the proceedings by our special correspondents. A description is given of the new water-power plant for the electric supply of Winnipeg, which was both described in a Paper, and visited. Among the Papers read before the Engineering Section was one by Mr. E. A. Watson, describing quantitative experiments regarding the atmospheric or "corona" losses with high continuous-current pressures, and one by Prof. E. W. Marchant on the calculation of charging currents in three-phase cables. Mr. Osmond Higham also read a Paper on "International Electrical Standardisation." A few Papers of electrochemical interest were read in the Chemical Section. (Page 835.)

THE Schäfer system of artificial respiration for applying to persons unconscious from electric shock is described in an illustrated wall sheet issued by the Royal Life-Saving Society. (Page 838.)

SOME new designs of iron-clad fuse-boxes, which can be built up from separate units, and also a new design of roller bearings, are described on pages 839 and 840.

A TRANSMISSION scheme on the Thury high-tension continuous-current series system, using a maximum pressure of 100,000 volts, is to be installed in Savoy. (Page 840.)

MESSRS. BROWN, BOVERI & Co. have received an order for five machines, each to give 17,000 k.v.a. at 11,000 volts. These generators, which run at 250 r.p.m., will be some of the largest that have yet been constructed. (Page 840.)

A NEW electric safety lamp for mines, combining an electric glow lamp and an arrangement for testing for the presence of gas, is described on page 841.

IN connection with the meeting of the Institution of Mining Engineers at Newcastle-on-Tyne last week, Messrs. Reyrolle gave an interesting demonstration of mining switchgear, &c., at their works. (Page 841.)

IN reply to a question in the House of Commons, the Postmaster-General has stated that the Wireless Telegraphy Act, renewed in 1906 for three years, will be renewed again to the end of next year, and that there appears to be no necessity to alter it in any way. Considerable progress is being made in France, Spain, and Morocco by the Compagnie française de télégraphie sans fils. (Page 841.)

MESSRS. Siemens Brothers Dynamo Works Ltd., have brought out a new series of traction motors with commutating poles, which enable advantage to be taken in their control of field variation to a greater extent than previously. Considerable economy is claimed for the new control arrangement. Motors of this class have already been supplied to the Hull Corporation tramways and elsewhere. (Page 842.)

THE accounts for the Aberdeen Electricity Department show a net profit of £227 for the past financial year.—A net profit of £678 has been made on the Bradford electricity undertaking.—An underground electric railway is to be constructed in Buenos Ayres. —A surplus of £2,182 on the Edinburgh electric lighting undertaking has been devoted to relief of rates. —A profit of £52,000 is reported on the Johannesburg electric light department, and of £44,100 on the tramway undertaking. (Page 843.)

CONSIDERABLE extensions in the telephone system of the Transvaal are contemplated. (Page 845.)

AT the meeting of the Underground Electric Railways Co. in London last Tuesday, a substantial improvement in the affairs of the company was reported.—The report of the United Electric Car Co., although disclosing a satisfactory financial position, records that the output of the works has been considerably below its capacity on account of slackness of trade.—The annual report of Messrs. Dick, Kerr & Co. records a profit of £28,168. A 6 per cent. dividend is recommended. (Page 847.)

ON Saturday last a meeting of some 450 students of the International Correspondence Schools was held in London, and at a dinner in the evening some interesting statistics with regard to the progress made by the schools were given. (Page 848.)

THE WELSBACH CO. AND THE METAL FILAMENT LAMP

THE Welsbach Incandescent Gas Light Co., Ltd., of gas mantle fame, announce that they are prepared to sell metal filament electric lamps. They do more than this, however; they offer to remove the whole of the carbon filament lamps from any existing installation, and replace them with "Welsbach-Aur" lamps, accepting as payment the amount which the consumer saves in his electric lighting bill for a quarter's consumption, compared with the corresponding quarter of the last year.

How those electrical contractors who are not agents for the Welsbach Co. will take this matter we do not know, but in the meantime there is a more interesting aspect to the case.

In the announcement, there appears above the offer, "Remember that the electric metallic filament lamp was invented by Baron Welsbach, and see that the trade-mark 'Aur' appears on every lamp."

Now it is true that the tungsten lamp was invented by Baron Auer von Welsbach (and also, it may be mentioned, was invented independently by Drs. Just and Hanaman a year previously), and patented by the Deutsche Gasglühlicht Aktien Gesellschaft (Auer-Gesellschaft) in this country. The Auer patent is No. 19,379 of 1905. Both these patents, however, are owned by the General Electric Co., Ltd., and are used in the manufacture of the Osram lamp; the General Electric Co. have granted no licence to the Welsbach Incandescent Gas Light Co., and, in consequence, the lamp which the Welsbach Co. supply cannot be the lamp invented originally by Baron Auer von Welsbach. Not only do the General Electric Co. own the Auer von Welsbach fundamental patent, but they also own a number of his company's subsequent patents. It has been suggested to us that the lamp offered by the Welsbach Co. is either not made under a Welsbach patent at all, or else it is made under a more recent Welsbach patent evading the patent for Baron Auer von Welsbach's original invention; otherwise it would be an infringement of the Baron's original patent. A further announcement on this point from the Welsbach Co. would be welcome.

Development of Water-power in Norway.—The Norwegian Parliament has just passed a law which will limit considerably the development of the water-power of the country, especially by foreign concerns. According to this Act, all water powers of over 1,000 available h.p. which are developed in the future by industrial companies, whether Norwegian or foreign concerns, will become the property of the State on the expiration of the concession. Any foreigner must obtain a State concession before utilising any Norwegian water-power, and these concessions extend over a period of between 60 and 80 years. According to the *Elektrotechnischer Anzeiger*, on the expiration of the concession, not only the water-power, but all the machinery, buildings, and hydraulic works connected with the same become the property of the State without any compensation to the owners. Those parts of the installation which do not belong to the hydraulic works can be acquired by the State at their value, or must be removed within a certain period.

THE WILLANS IMPULSE STEAM TURBINE

We are able this week to give an advance description of a new impulse type of turbine which Messrs. Willans & Robinson, Ltd., are placing on the market, and offering as an alternative to their Willans-Parsons turbine. The turbine in question is being built in sizes up to 1,500 k.w., and its general construction can be seen from the accompanying illustrations. Fig. 1 shows a turbine of 1,000 k.w., running at 3,000 r.p.m., and direct-coupled to a water brake for testing purposes. It will be noticed in this view that the top cover of the turbine casing is removed, leaving exposed the first wheel, and showing the nozzles in position which feed on to the second wheel. In Fig. 2 are shown the two wheels of the turbine rotor, from which it will be gathered that each wheel has mounted on its periphery two rows of blades.

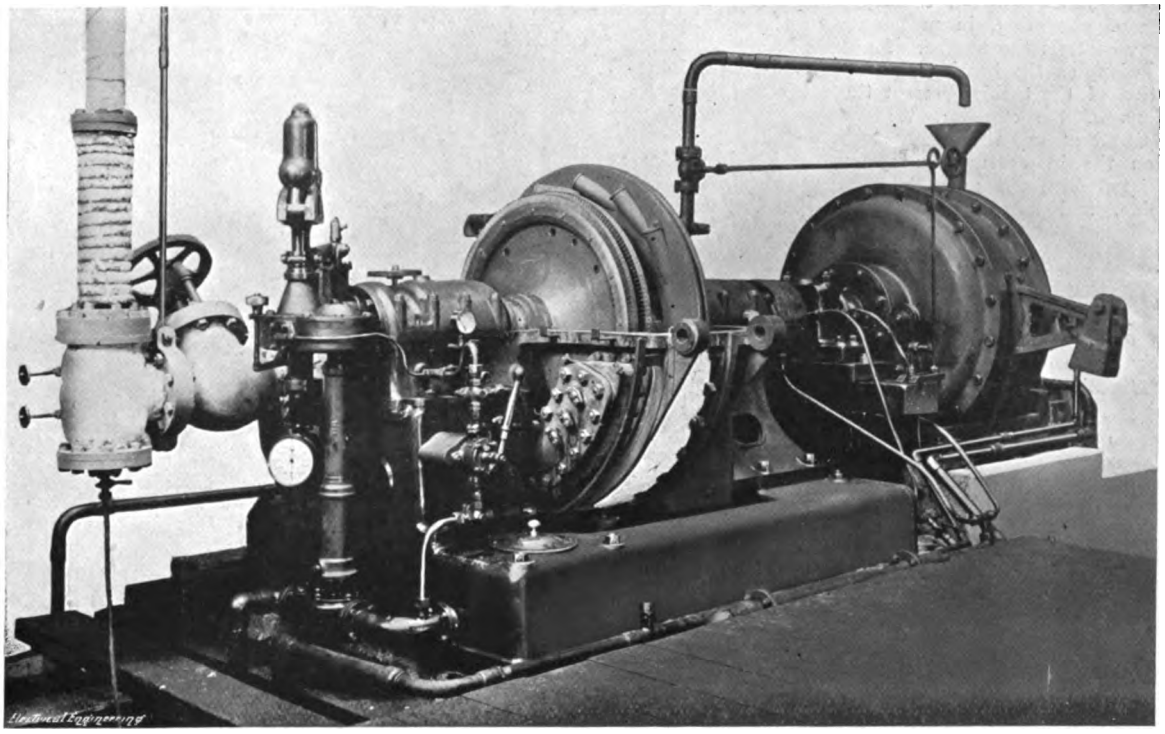

Fig. 1.—1,000-kw. Willans Impulse Turbine, with Top Cover of Turbine removed, showing one Wheel and Nozzles for Second Wheel.

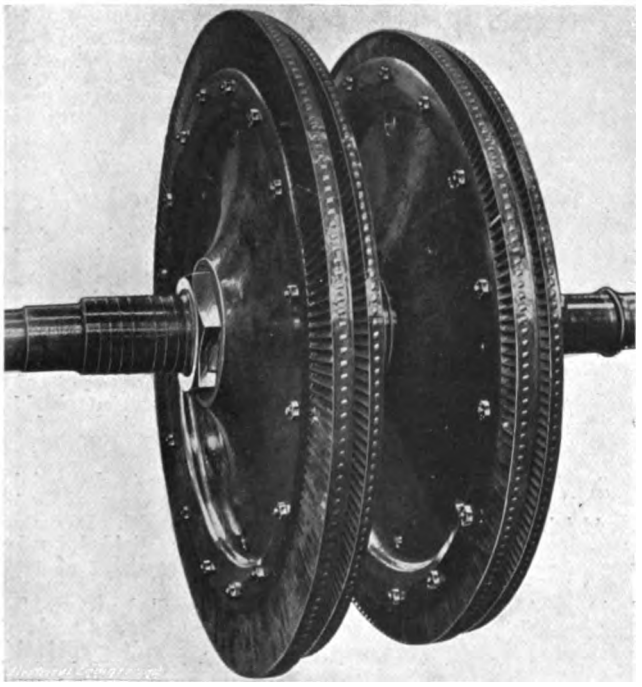

Fig. 2.—1,000-kw. Willans Impulse Turbine, showing the two Rotating Wheels, each Wheel having two Rows of Blades.

In this type of turbine the steam, after expanding and acquiring maximum velocity, acts upon one, two, or three sets of moving blades (in the present case upon two sets), each row being designed to extract a certain amount of the total velocity from the steam in such a way that the steam, after leaving the last running row, has given up nearly all its useful energy to the wheel. In between each running row of blades there is a fixed row of blades for bringing the steam back to its original direction of motion. This method of converting the energy in the steam into useful work, by means of several velocity stages to one pressure stage, allows a compact and neat form of turbine to be built, and has the advantage of permitting the impulse system to be employed in conjunction with a small number of reduced diameter wheels.

The turbine here illustrated follows in regard to details of governor gear, bearings, and accessories, exactly the lines of the well-known Willans-Parsons turbines, the only difference being that the impulse system entailing one, two, or at most three high-speed wheels, is substituted for the numerous rows of blades required in turbines on the Parsons principle.

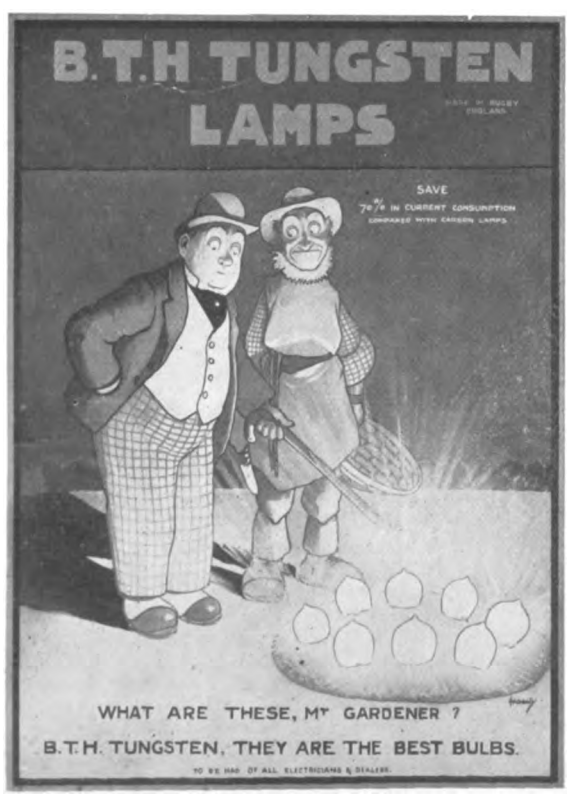
There are several details in the design of this turbine which are of interest, and which may be briefly touched upon here. For some considerable time Messrs. Willans & Robinson, Ltd., have been engaged in finding a blading material which would combine strength and resistance to erosion, and, finally, they have produced an alloy which possesses the necessary properties, and which they are able to cast in their foundry. The individual blades are designed to form their own shrouding, to ensure their own fixing in the wheel, and to arrange their own spacing with the result that the process of blading consists merely in sliding the individual blades, one after the other, into a groove cut in the wheels through a "window" specially provided for the purpose. The process of blading has in this way been reduced to an extremely simple matter.

The standard Willans steam gland is used for packing the end glands of the shaft, and also for packing the discs in the turbine through which the shaft passes. This method of making a joint round a rotating shaft, although it entails the use of a small quantity of steam, has the advantage that any possibility of trouble rising due to the fouling of the shaft, is avoided. These internal glands, being one of the most important points

Digitized by Google

in the design of an impulse turbine, have received special attention at the hands of the manufacturers.

The casing is arranged to open on hinges, as in the case of the Willans-Parsons turbine, and the general design of the turbine casing is arranged to give easy access to the working parts. The standard Willans arrangement is used for governing, in which a small governor acts directly on a double-beat throttle valve. Hand-operated nozzles are provided for limiting the range over which the governor has control. The particular experience which Messrs. Willans & Robinson, Ltd., have had of turbine governing has led them to adopt and recommend this system of governing, in preference to the one in which the governor controls the number of nozzles in operation.



In conclusion, as the bearings, governor gear, and, in fact, every portion of the turbine except the rotor and casing, are reproductions of the standard Willans-Parsons turbine, they can be replaced at any time from stock, and are being manufactured on the interchangeable system, which has been so long associated with the manufacture of the Willans central valve engine, and more recently with the Willans-Parsons turbine.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

CONTINUOUS-CURRENT DYNAMOS AND MOTORS.—Messrs. Bruce Peebles & Co., Ltd. (Edinburgh) have issued a new pamphlet dealing with their latest designs of continuous-current self-contained dynamos and motors. These range up to about 200 h.p., and protected, semi-enclosed, single and double gauze enclosed, and fully enclosed machines are listed. The frames are all of cast steel, divided in the larger sizes, and the end brackets are so arranged that the machines can be fixed to wall or ceiling without alteration. In most cases, especially in the higher voltages, where variable speed is required, commutating poles are provided. Ball-bearings can be fitted if required in the smaller sizes. All the machines conform with Home Office and the insurance rules. A special feature of the list is the completeness of the dimension sketches and the tables of standard outputs.

METAL FILAMENT LAMPS.—We reproduce on a reduced scale a delightful example of Mr. John Hassall's work in the form of a design which the British Thomson-Houston Co. are

issuing, both as a poster, 20 in. by 30 in., and as a 10-in. by 12-in. show-card, to call attention to B.T.-H. tungsten lamps, by a novel application of electricity to horticulture.

EAST LONDON COLLEGE. We have received a copy of the calendar of this College for 1909-10. The electrical engineering course was described in ELECTRICAL ENGINEERING, August 26th, page 761. To the equipment of the school of engineering, civil, mechanical, and electrical, considerable additions have been made during the past year. A considerable sum of money was placed at the disposal of the College Committee for these purposes by the Drapers' Company, who specially earmarked a portion of their benefaction for the improvement of the College library, which is now housed in comfortable rooms, and possesses a very fair collection of important and representative works dealing with the various subjects in the College curriculum. As the only school of the University of London in the faculties of arts, science, and engineering in the eastern half of the Metropolis, the East London College is steadily gaining in reputation and influence among the people of East London and of the populous eastern suburbs.

BELL TRANSFORMERS.—A leaflet from the Foster Arc Lamp & Engineering Co. (Wimbledon) calls attention to a special series of small transformers for bell ringing which the firm have introduced to avoid the use of batteries where an alternating current supply is available; 6 or 8 volts is given on the secondary.

TRACTION MOTORS.—A pamphlet from Messrs. Siemens Brothers Dynamo Works, Ltd. (Caxton House, Westminster, S.W.), in the form of a reprint of an article in the September issue of the *Electron*, deals with the new designs of commutation-pole traction motors described in an article on page 843 of this issue.

FORCED LUBRICATION.—A new publication is being issued by Messrs. Vickers, Sons & Maxim, describing, with the aid of some excellent coloured illustrations, a system of forced lubrication which they are introducing. The main principle in this method of lubrication is the employment of a small separate oil pump for each bearing, worked by an excentric on the shaft itself. This pump delivers oil through a channel leading to the under side of the bearing bush, with a pressure sufficient to lift the shaft and cause it to float on a thin film of oil. Rigid and swivel bearings are illustrated, fitted up on this system and quite self-contained. Separated lubricators are also made, consisting of an assemblage of pump units of similar nature, each with a separate adjustable sight feed supply arrangement. The system is also adaptable to railway rolling stock bearings.

Aeroplanes and Overhead Wires.—The Ottawa correspondent of the *Times* states that when an aviator was ascending from the Ottawa Fair grounds on September 16th the propeller of his machine caught in an overhead electric wire, which broke and fell to the ground. Four persons received shocks, and two were taken to hospital.

Correspondence Instruction in Aeronautics.—The British Correspondence School of Electrical Engineering (56 Maiden Lane, W.C.), is making a new departure of instituting a course of instruction on aeronautics. We have before us a synopsis of the nine lessons composing the course, from which it appears that full attention is drawn to the actual work of most notable experimenters in flying and dirigible ballooning, to illustrate the fundamental principles involved. Doubtless continual modification will be made in the subject-matter to keep pace with the rapid advances being made.

Lift Accident on the City & South London Railway.—Col. Druitt's report on the lift accident which occurred on August 2nd at the Oval Station of the City & South London Railway has now been issued. The lift is a hydraulic one, and the sudden descent of the car was caused by a broken pipe leading from the working cylinder. The same accident has happened before, but there are no safety devices which could have come into action. The cage rebounded some nine inches, when it was arrested by the slack cable device. The pipes are to be thickened on all the ten lifts of similar design, and relief valves are to be provided to guard against the effect of a momentary rise of pressure caused by a too sudden checking of the lift. The other lifts are electrically worked, and are fitted with safety devices depending on the speed of the cage.

New Advertising Sign.—A very ingenious electric sign, giving a kaleidoscopic effect, is on view in the showrooms of Messrs. Rashleigh Phipps & Co., of 147 Oxford-street, W. It consists of a circular metal frame, 3 ft. in diameter, divided up into a number of irregularly shaped partitions by strips of metal about 3 in. wide placed on edge. Each partition is enamelled inside, and contains an 8 c.p. lamp, also enamelled on top. The centre partition is in the shape of a Maltese cross, and variously coloured diamond-shaped partitions are arranged around this. The lamps are switched on in groups. There are 50 lamps in all, and about half this number are on at once. By means of a special thermal switch, the various groups are switched on and off irregularly, there being about 100 changes every minute. In all there are 500 different combinations. A modified pattern with a 6 in. margin for lettering is on view in the window, and has attracted considerable attention. This device consumes about one half a unit per hour. It is seen to the best advantage from a distance of about 30 ft.

ELECTRICAL INSTALLATIONS IN COAL MINES

THE Select Committee which is to consider the framing of modifications in the Special Rules for the use of electricity in mines is not yet definitely nominated. As there is still time, we would urge the Government to include on the Committee representatives of the Coal Owners' Association, and of the Miners' Federation of Great Britain. A large Committee is not necessary, for as witnesses will be examined, it will be possible to obtain the views of all classes interested, and of any engineers who have had prolonged experience in the applications of electricity in mines. On the other hand, it would not be right to constitute the Committee merely of Home Office officials, with, perhaps, one outside expert. Both masters and men will feel more confidence in the result if each of the bodies representing them were invited to nominate one of its own members to sit on the Committee.

The uneasiness felt by the men, on account of the recent accidents that have occurred, more particularly the explosion at the West Stanley pit, is instanced by a motion recently put before the Council of the Durham Miners' Association that they should request the coal owners to remove electrical machinery and cables from their pits. The Council decided, however, that this action should not be taken in view of the appointment of the Select Committee to remodel the Special Rules. It must not be forgotten, moreover, that it is by no means certain that the explosion in the West Stanley pit was ignited by sparks from the electrical installation; in fact, there is a growing feeling in colliery circles in Durham that the explosion may have been due to quite another cause.

We have received a number of letters on the necessity of the Special Rules for the use of electricity in mines being made more stringent:—

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In your issue of September 2nd you give a very interesting article on "Electricity in Mines." I find on reading Mr. John Wilson's question to the Home Secretary, that it was only a conclusion that electricity was the cause of the explosion at the West Stanley Colliery. The state of the electrical apparatus at the moment of the explosion is a very difficult matter to determine, and of course an examination of the same directly after does not convince one that because it is faulty now it was so before. As an example of the manner in which electricity is blamed for mishaps I might add that at a certain colliery I have in my mind a fire took place on the pit top and originated in a certain building. Of course it was all electricity that had caused it when inquiries came to be made until it was proved that there wasn't an electric cable in the building at all.

I was very pleased to see that Mr. Wilson asked for a commission to be arranged to inquire into the use of electricity in mines, and that the Home Secretary has consented to do so, as, notwithstanding what I have said above, I think there is plenty of room to improve the existing rules. I know of several collieries where the electrical plant is a disgrace, and that the "competent person" is an engine oiler or something to that effect. I quite agree with Mr. H. J. Fisher that the committee selected should consist of only persons of practical experience in the application of electricity to mining. What is the use of having makers of apparatus? How do they know the defects? It is the person who has the upkeep of these that can tell their defects. I think the idea of Mr. Fisher's that all apparatus should pass a Government inspection and be placed on a permitted list is splendid; then we should get articles fit for use, and not toys.

In the latter part of your article you deal with that which I consider a very important matter in connection with electricity in mines, namely, the use of armoured cables continuously bonded and earthed. I think that if all cables were armoured, and that the earthing was tested periodically, that we should hear of less deaths from shocks than we have done in the past. I find on looking over the special rules adopted for the installation and use of electricity in the mines of New South Wales that they are, as you say in your issue of September 9th, far more stringent than those now in use in our own country, and I think some of their rules could to advantage be added to our own, especially those you name.

Yours faithfully,

Burnley, Lancs. P. D. COATES,
September 11th, 1909. Electrical Engineer.
Exors. Col. Hargreaves, Burnley,
Habergham and Marsden Collieries.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—For some time past many of those holding the position of colliery electrical engineer have been quietly working to remove the defects of electrical plant which come under their control. During the fight for mastery they have contended with fire, water, gas, falls of stone, sparking from haulage ropes, the encroachment of mice, native cussedness, and the prejudice of the manufacturer.

We have reached the psychological moment when drastic measures must be taken to regain the confidence of those who use or wish to use electrical machinery for mining purposes. There is apparently a tremendous amount of evidence against its use under the present uncertain conditions, and to regain this confidence we must be in a position to place forward a system which will eliminate the defects now in existence. It is not sufficient to say that a dangerous place must be guarded; we must remove the cause which makes a guard necessary, and it is high time this class of work was standardised.

The use of unprotected rubber-covered cables has long been condemned; even a three-core bitumen-covered cable will set fire to timber if not carefully looked after. For a 500-volt three-phase system we have used paper-insulated, lead-covered, armoured cable with great success. When jointing we use a special joint-box having clamps at each end for the armouring, and a gland for the lead, into which molten lead is run, thus making lead, armouring bonding cable, and box all one. At the same time the lead seals the box, so that moisture cannot penetrate the compound. A 3,500-yard length of cable connected by this method gave a combined armouring and lead resistance of about 3 ohms.

The most satisfactory three-phase system I have in mind is one using an earthed neutral, the armouring of the cable actually being the neutral or earthed return to the main generator. In conjunction with this system, it is necessary to use an automatic switch actuated by a leakage coil in series with the armouring or earthed return, so that the motor will automatically switch itself out of circuit should the insulation become faulty. The tripping arrangement of the switch can be made very delicate, and will release with a small leakage current before internal or external damage can be done by sparking. The earthing of the armouring is carried out by means of the rising main and earth plates at pit bank. The leakage obtained from a machine 3,500 yards in-bye amounted to about 80 amperes. The earthing of plant to still or running water is a fallacy, this method giving between 500 and

Digitized by Google

1,000 ohms resistance, instead of 3 ohms, with efficiently earthed armouring.

Most leakages which occur are traced to faulty ammeters, and wherever possible these are connected to the dead side of the machine switches.

Some time since, we proposed the following system for use, with earthed neutral, on an extensive cable system. In-bye each machine switch is fitted with a trip coil, which is actuated by leakage. At the distribution board, near the shaft, the earth returns of the separate circuits are connected in series with leakage tell-tale indicators; from each of these tell-tales an auxiliary battery circuit is connected to corresponding tell-tales at the power station. In the main leakage return or neutral is connected a special recording ammeter, which records all leakage on the system. From the foregoing it will be seen that all leakages are automatically located and recorded. Where you have as much as 20,000 yards of cable in use it is advantageous to know where leakages originate.

The sparking from haulage ropes can easily be remedied by the use of rope or belt drive, and for a fiery mine it is a mistake to earth any machine except by the armouring of the cable. While treating with this subject I may mention a case of sparking from haulage rope which was not due to leakage. In this case, two in-bye haulage ropes were crossing, and frequently came into contact. When in contact vicious sparking was noticed, and at once put down to leakage. The machines and cables, running parallel with the ropes, were tested, but no leakage could be traced. The sparking ceased as soon as the machines were stopped, and increased as the current flowing through the cable increased. While the machines were standing, a heavy leakage was purposely caused to flow by the earthed return, and no sparking could be detected from the ropes. We could, therefore, only put this down to the inductive effect of the cables which at places ran very close to one of the haulage ropes. Duplicate cables were in use, one bitumen unarmoured and one armoured. When these were examined two fuses were found blown on one of the cables, and after replacing these the sparking disappeared entirely from the ropes. We would like to hear if others have noticed the same phenomena.

Is there any reason why efficiently earthed armoured cables should not be carried along the travelling way instead of the rolley way, as is now the practice? They would then have better supervision, be clear of runaway tubes, and freer of falls of stone. Whenever possible we put the cables behind the timber, by which they are greatly protected.

For a fiery mine an ideal cable would be one having a lead covering wire armoured, and finished off with bitumen, so that external sparkings due to exposed armouring could not take place. By earthing the cable at bank, and keeping it clear of the rolley way, very little danger of sparking would occur.

Perhaps a word or two with reference to switches will not be out of place.

Independent of the presence of gas, many of the modern switches supposed to be enclosed, fool proof, and gas-tight, are impossible for practical use. We have seen these burst to pieces by a heavy short circuit, and it appears that only a liberally designed oil switch is at all satisfactory. We have found it necessary to alter many of the switches which have come under our control.

The day will come when the stator winding of a three-phase motor will also be immersed in oil. The difficulties in connection with this are not insurmountable.

Experiments on the effect of sparking in gas will no doubt give good results, but at the same time there is no reason why the first cause of sparking on electrical plant should not be met and overcome.

We anxiously await an experienced committee to deal with and clear up these various and important questions.

Ashington Collieries, Northumberland.
September 13th, 1909.

T. McKIE.

To the Editor, ELECTRICAL ENGINEERING.

DEAR SIR,—I beg to thank you for drawing my attention to the article on "Electrical Installation in Coal Mines," which appeared in your issue of the 2nd inst. I do not know that I can add very much to the opinions so ably expressed in that article, as I am, broadly speaking, in strong agreement with practically everything stated therein. I may be pardoned for dwelling on one or two points. In common with many electrical engineers interested in the electrical equipment of mines, I feel that the time is now ripe for the revision of the Home Office Regulations relating to the use of electricity in coal mines. Let us have them fewer, more definite and stringent. I do not disguise the fact that such a revision will probably mean a temporary set-back for electricity in coal mines, especially for the smaller pits; but, in my opinion, the revision would act as a dose of medicine, and the ultimate result would be a mutual benefit for the coalowner and the electrical industry.

Competent supervision by experienced men should be insisted on for all electrical installations in collieries, and this is really the crux of the whole question of electricity in mines; it is also the rock on which opinions, especially coalowners', will split. Small collieries with small installations can, in some fairness, argue that they cannot afford to pay for an experienced electrical engineer, and it may be these collieries would even prefer to discontinue the use of electricity. In most cases, however, electricity has given the owners so many advantages that they will realise that an experienced man in charge of their undertaking will pay them. As matters now stand in many collieries, the repair bill due to bad supervision would pay for an experienced man. Even leaving this out of the question, the difficulty might be solved, in smaller pits, by periodical inspection by an experienced man.

In any event, I think this question of competent supervision will solve itself in time. The formation of the new Mining Electrical Institution, and the greater knowledge of electricity which the coming generation of mining engineers and colliery managers are bound to have, will greatly help in this much-desired consummation.

The most dangerous part of an electrical installation, from the point of view of explosion and shock, is, of necessity, the cable, owing, of course, to its greater liability to damage. I am particularly interested in the cable question, and I am bound to admit that armoured cables continuously bonded and effectively earthed are the right thing for collieries. Mr. Nelson, the Home Office Electrical Inspector for Mines, puts the case of armoured cables very well in his reply to the discussion on his recent Paper before the Institution of Mining Engineers (*vide* the last published transaction of the Institute of Mining Engineers). There must, in addition, however, be competent supervision, inspection, and testing. Without these I am not prepared to advocate whole-heartedly armoured cables, even when the system has been installed perfectly to begin with. I know of more than one instance when an installation of armoured cables has originally been well bonded and earthed; falls, however, have occurred and damaged the cable, which has afterwards been repaired without bonding across the armour at the repaired portion. A much greater danger has, consequently, been constituted than with an unarmoured cable system. More than one fatal shock has been sustained under such conditions. In fact, I would not be prepared to deny a statement that more shocks and more fatal accidents have been caused on armoured than unarmoured cable systems.

When called upon to advise on the type of cable to be adopted in collieries, I have had to carefully consider the circumstances at each individual colliery, and very often I have been compelled to advise on unarmoured cables, as, on the whole, constituting the lesser danger. There is no doubt that the majority of present colliery managers favour unarmoured cables owing, however, probably to the lesser risk of stoppage and this has had its effect.

The accident you describe in your article illustrates much of what I have written above, and points the moral. However, there is no doubt that armoured cable with competent installation and supervision, aided by more definite rules, is the type of cable for collieries, and must work towards the minimising of danger of shock and explosion.

In spite of all additional protective devices and these should

Digitized by Google

be designed to have the minimum possibility of stoppage of the plant consistent with safety—there is bound to be a certain amount of risk. In other branches of colliery engineering there are decided risks, and I am one who is disposed to think that the present outcry as to the danger of electricity in mines, founded on, unfortunately, too frequent examples of bad equipment and supervision, is, after all, a little exaggerated, and will die away as colliery officials realise that electrical installations require looking after as well as winding engines, ropes, and other parts of colliery engineering equipment. Definite rules will certainly tend to produce this effect.

Trafford Park. Yours faithfully,
September 16th, 1909. George G. L. Preece.

To the Editor of Electrical Engineering.

Sir,—In reference to your article in the issue of September 2nd, stating that a Committee is to be appointed to revise the Home Office Regulations relating to electrical installations in mines: There has been a great deal of discussion since the West Stanley explosion as to whether or not electricity was the primary cause of this particular explosion, and no doubt the suspicion still rests in the minds of a great many people that electricity was a great contributor, if not the actual means of igniting the explosive mixture, and thereby causing the disaster. It may or may not have been caused, as Mr. R. Nelson suggests, viz., by a fall of roof severing the 7/20 rubber cables. My experience goes far to prove that it is quite possible for an explosion to occur in this manner, and I regard this as a very likely cause; but I have been assured by one who visited the scene not very long after the disaster that the coal-cutters were regarded by a great many, who spoke on good authority, as being the more likely to have ignited the explosive mixture. I have, however, known a fall of roof to sever rubber cables, and the cables to arc at the point of severance, but, of course, not in a fiery mine.

The following is another instance, not quite similar, yet sufficient in itself to cause disaster, had the mine been a fiery one. A by-workman at a Yorkshire colliery was working in the engine plane, where a concentric, lead-covered (but not armoured) cable was laid. In drawing certain props, he dislodged the cable from its fastenings, and, instead of reporting it to the proper quarter, he thought he would fasten the cable up by himself. He could not quite see how to do it unless he drove a nail through the cable; he did so, and when the attendant at the generating station located the trouble, he found our friend the by-workman coming to the pit bottom with a sore head, and a story of the pit having exploded.

Now, I have cause to believe that Scotland is not the only, nor the worst offender, in respect of proper precautions regarding safe working and inspection, where electricity is installed in coal mines. I have heard of a certain Inspector of Mines who, when he visits one particular colliery, very often takes the insulation from the joints in the cables down the pit. This implies mistrust in the man who makes the joints, and if the electrician employed is anything resembling the terms of an advertisement I saw not long ago, the mistrust is certainly justified. The advertisement was as follows:—"Wanted, an Engine Plane man. Must be able to splice ropes, repair electric bells. A knowledge of Electric Light and Power would be a strong recommendation." On reading this, it certainly appears that at this particular colliery electric light and power plays second fiddle to rope splicing.

The employment of unskilled and incompetent persons in charge of many colliery installations is a fruitful cause of a great many accidents which occur where electricity is installed in mines. In regard to cables in use in mines, I am of the opinion that when the Special Rules are revised there ought to be a rule enforcing the use of armoured cables continuously bonded and earthed, and that a test must be taken each day before 7 a.m., and the result recorded in a book kept for that purpose; and I think that circuit-breakers ought to be made compulsory. I am also of the opinion that there should be a recommendation enforcing the employment of a skilled and competent person in charge, and held responsible for the installation of electricity in each mine. What is the use of putting down first-class installations and taking the greatest precautions for safety, when an unskilled man is given charge of such installation. I have great hopes that the new Institution of Mining Electrical Engineers will do much good in this respect, and if only the managers would co-operate with them they would then be sure of success, and we should hear less of accidents caused by electricity in mines.

Pontefract, Yours faithfully,
September 11th, 1909. J. W. Jackson.

To the Editor of Electrical Engineering.

Sir,—This is a subject a great deal could be said on, and my opinion regarding the special rules is, that it is time they were revised. In a true sense they are fairly stringent, and if firmly adhered to no doubt there would be less accidents. But they are too ambiguous, and far too flexible for the majority of people connected with them. Plain language is what is wanted, so that it cannot be moulded to suit the occasion. During my experience I have observed that mining companies prefer to buy electrical fittings and apparatus of a cheap quality, such as were never designed for mining work. Such apparatus would, or might be, safe enough and good enough, too, if it were confined to a drawing-room, but will never be safe nor satisfactory either, in a coal mine. I think in the revising of the special rules a clause should be included, clearly stating that the use of such apparatus in a coal mine is illegal, and that all electrical apparatus and fittings installed in a coal mine must comply with the special rules in every detail. A description of approved fittings could also be included in the special rules.

There are plenty of firms at the present time manufacturing good and reliable fittings, specially designed for mining work, but I suppose, because they are a little dearer in price, they are rejected for cheaper articles. As long as the installing of these supposed cheap fittings is allowed to exist there will always be trouble and unnecessary danger. I said "supposed cheapness," because it is nothing more, they are much dearer in the end; before the fittings have been in use many months they have cost more in time and renewals than would buy another set of good fittings.

As regards cables in coal mines, in lots of mines that I know of, where miles of vulcanised bitumen and rubber-covered cables are in use, without any armouring of any kind, it is a very difficult matter to prevent accidents from shock. Some rubber and adhesive tape are the common materials supplied for repairing. Such materials as the above are useless, or about as good as nothing in many of the situations I have seen. Joints and bare parts covered with the above, could be handled all right the day they were covered, but on examination two or three days later, although in quite a dry position, and no water dropping near them, you would observe little beads of water adhering to the adhesive tape all over, and on touching, you will receive a severe shock. I think the care of such cables should be commented on in the special rules. I am perfectly certain that cables in the above condition would be highly dangerous if used in a section where an accumulation of an explosive mixture was found to be present.

Before concluding, I may say there are many more points just as worthy of serious consideration as those referred to above.

I remain, Yours truly,
September 14th, 1909. Black Faced, M.I.M.E.E.

To the Editor of Electrical Engineering.

Sir,—In connection with earthing motor frames and cable armour underground it should not be forgotten that any earthed envelope enclosing live wires must be electrically continuous throughout, and therefore must be considered to start at the generator, whether rotary or static. With direct-coupled generators the whole of the pipe system in the mine, both air and water, is usually in direct metallic connection, *viâ* the boilers, with the core discs of the generators, and, even if the whole of the cable armour and motor frames are earthed on a plate buried at the collar of the shaft or in the sump, a man standing on an air pipe may still get a severe shock from them.

Yours truly,
September 14th, 1909. F. H.

On Friday last, the adjourned inquest was held on the death of a man, which occurred on September 6th in the Shildon Lodge Colliery, near Bishop Auckland, Durham. The man was in charge of a 195-b.h.p. pump motor supplied at 2,200 volts. He noticed sparking at one of the terminals of the switch, probably due to a loose contact; and, contrary to orders, he went to the back of the switchboard to examine this. He switched off the current from the motor first, but the line terminals, of course, remained alive, and he touched these and so received a fatal shock. Mr. Robert Nelson, Electrical Inspector of Mines, and Mr. Walker, the local Home Office inspector, were present at the adjourned inquest.

The Irish Telephone System.—In the House of Commons on Monday, Mr. J. P. Farrell asked the Postmaster-General whether, if a guarantee could be secured from the urban areas of Galway, Athlone, Mullingar, Cavan, Longford, Boyle, and Sligo, together with the promise of a given number (not less than ten) of subscribers in each of these townships to a telephone service, he would take steps to extend the trunk telephone system from Dublin to Galway, and from Dublin to Sligo and to Cavan *viâ* the Midland Great Western Railway line immediately? Mr. Buxton, in a written reply, stated that he had already offered to recommend to the Treasury an extension of the telephone system to Mullingar, Athlone, and Galway under guarantee, but that an offer to provide part of the guarantee had been received from Athlone alone. A direct extension to Cavan would, he said, be very costly, but if guarantee could be obtained for an extension to Clones, he would quote guarantee terms for a further extension to Cavan. In the same way extensions to Longford and Boyle could not be undertaken with any prospect of a reasonable return except in connection with a scheme for serving Mullingar. Guarantee terms for an extension of the trunk system from Enniskillen to Sligo had been arranged.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 16th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

25,715/07. **Advertising Signs.** R. F. VENNER. Holes are punched in the signboard along the lines of the letters or designs for the reception of perforated transparent beads, which are threaded on wire passed alternately from the front and the back of the board through successive holes. The beads may be illuminated from behind, or may be hollow, and contain spark gaps inside. Three claims, two figures.

17,611/08. **Ductile Tungsten Alloy.** SIEMENS & HALSKE AKT.-GES. Tungsten alloyed with from 8 to 10 per cent. of nickel is more ductile than pure tungsten, and can be drawn into filaments. According to this invention, the formation of the alloy is hastened by the addition of from 0·5 to 1 per cent. of iron, cobalt, or copper. One claim.

18,054/08. **Prevention of Blackening of Lamps.** W. C. ARSEM. In the opinion of the inventor, the blackening of metal-filament lamps may be practically obviated by removing from the bulb the readily ionised mercury vapour which may have reached there. For this purpose the stem holding the filament cage is coated with silver or other mercury-absorbing material. The silver may be applied by painting the stem with silver oxide dissolved in ammonia and heating afterwards. This liquid may contain silver in suspension. As an alternative, silver foil may be wrapped round the stem. One claim.

18,513/08. **Induction Furnace.** RÖCHLING'SCHE EISEN- und STAHLWERKE GES. and W. RODENHAUSER. The iron core is formed by two bunches of laminations each bent into the form of the letter U, and interleaved or butted together at the extremities, so that the two pieces are at right angles. The thickness of the assembled laminæ is considerably less than their width in order to reduce magnetic leakage. A wide working hearth is provided between the two vertical limbs. Four claims, three figures.

21,311/08. **Crane Gear.** J. MARSHALL, J. FLEMING, and R. S. ANDERSON. In electric cranes of the "free barrel" type, in which a clutch is interposed between the motor and the barrel, the load lowering and holding brake generally acts directly on the barrel in both directions, brake and motor control being interlocked. Between the movement of the controller releasing the brake and the insertion of the clutch, however, there is necessarily an interval during which the load begins to fall, and to avoid this the present invention provides for a separate brake drum geared to the winding barrel through a ratchet clutch, so that the barrel is always free to turn in a hoisting direction. A friction clutch is placed between the barrel and the motor, and means are provided for releasing this clutch before releasing the brake. Three claims, two figures.

6,248/09. **Accumulator Plates.** ACCUMULATOREN-FABRIK AKT.-GES. The lugs are sheathed by bending thin plates of ebonite or other insulating material into the form required. These sheaths, which are pressed on, may cover the whole or only the sides of the lugs. The feet are made wholly of ebonite, with two tenons and a recess, corresponding with recesses and a tenon formed on the lead plate. These feet are made of the same thickness as the plate itself. Three claims, three figures.

8,283/09. **Regenerating Blackened Carbon Filament Lamps.** E. A. KRÜGER. After the bulb has been opened, and the carbon deposit removed from its walls by heating, it is evacuated, and a definite quantity of pure hydrocarbon is introduced, and the filament brought to incandescence by the passage of a current. This decomposes the hydrocarbon, and carbon is deposited on the filament. Two claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Dynamos, Motors, & Transformers: BARNES (*Breslauer*) [Compounding A.-C. generators] 11,558/08; ROBSON and MARSHALL [Electric grinding, milling, and boring machines] 20,988/08; SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*) [Portable drilling machines] 26,685/08; WHITE [Motor control] 6,567/09.

Electric Ignition: DUCROS [Sparking-plugs] 18,120/08; CLEVERLY and ANDERSON [Commutators] 21,740/08.

Electrometallurgy & Electrochemistry: SPILIOTOPOL [Cells] 18,115/08.

Heating & Cooking: COOPER and SHARP [Connections with silundum and other resistance rods] 22,627/08.

Switchgear, Fuses, & Fittings: FULLER [Fuses] 20,890/08; HOLME [Crane controller] 23,111/08; FLOOD [Switches] 3,628/09; HARCOURT and MARKHAM [Portable hand-lamps] 3,892/09; CONNER [Relay] 4,399/09; ALLGEMEINE ELEKTRICITÄTS GES. [Protective devices for A.-C. systems] 4,705/09; BRAND [Switchboard terminals] 11,267/09.

Traction: MACDOUGAL and MCKINNON [Signalling] 17,952/08; HIGGINS [Air brakes] 18,871/08; MOORLEY and DAVIES [Brakes] 22,189/08; TAYLOR [Signalling] 1,788/09; REINOEHL and WEAVER [Track-structures] 10,602/09; RAMSAY, CURLEY, and YOUNG [Brakes] 12,468/09; WESTINGHOUSE ELECTRIC CO. [Brakes] 15,725/09.

Miscellaneous: RITTERSHAUSSEN [Thermo-piles] 18,277/08; MÜLLER [Sounding-fork vibrator] 18,326/08; OSWALD [Power gas plant for ships] 5,581/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Incandescent Lamps: STEFANO [Variable intensity attachment] 19,465/09.

Opposition to Grant of Patent

14,483/08. **Fusing of Metal Filaments to Supports.** S. MARIETTI. Opposition has been entered to the grant of this patent, which is for tubular supports and leading-in wires and a method of fusing in the filaments. The specification was abstracted in ELECTRICAL ENGINEERING, August 5th, 1909, page 714.

Patent Surrendered

2,122/08. **Insulating Material.** W. CLAYPOOLE. This patent has been surrendered, probably in consequence of the application for its revocation which was made in August (see ELECTRICAL ENGINEERING, August 19th, 1909, page 750). The patent is for a substitute for ebonite manufactured by heating a mixture of carbolic acid, formalin, and caustic soda, and pouring the resultant liquid into moulds. The product, when hard and polished, looks like light grey porcelain. Other similar compositions were covered by the patent.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: SIEMENS BROS. & CO. (*Siemens-Schuckertwerke Ges.*) [Carbon holders] 11,169/05; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Mechanisms] 11,243/05, and [Ventilation of flame arc lamps] 11,705/05.

Distribution Systems, &c.: E. A. CAROLAN (*General Electric Co., U.S.A.*) [Insulating composition] 12,312/03; W. BACON [Cable armouring] 11,470/05.

Dynamos, &c.: K. KOCH [Metal brushes] 11,391/05; G. BERRY [Machine with sub-divided magnetic circuit] 11,600/05; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Self-starting single-phase synchronous motor generator] 11,703/05.

Electric Ignition: A. WINTON [Distributor] 14,688/03; F. H. DE VEULLE [Multiple-way switch] 12,418/04.

Electrometallurgy and Electrochemistry: C. M. HALL [Carbon electrodes for electrolytic separation of aluminium] 12,681/02; W. H. FELLOWS, E. T. PICKUP, and W. TICE [Regenerative primary cell] 7,133/05; C. LUCKOW [Regenerating secondary batteries] 11,353/05.

Heating and Cooking: BRITISH PROMETHEUS CO., and H. SKIPWITH [Cooking utensil] 12,214/04; G. TEUBER [Utensil with helical wire heating unit] 11,407/05.

Instruments and Meters: W. L. WISE [*Lux'sche Industriewerke A.-G.*] [Motor meter] 10,219/00; H. T. BARNES and H. M. TORY [Indicating resistance pyrometer] 12,253/04; BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts-Ges.*) [A.-C. motor meter] 12,336/04; H. BOURGEOIS [Pocket ammeters and voltmeters] 11,673/05.

Storage Batteries: C. LUCKOW [Regenerating sulphated plates] 11,353/05; A. SCHANSCHIEFF [Planté plates] 11,654/05.

Switchgear, &c.: G. A. MOWER (*H. H. Cutler, U.S.A.*) [Motor starter] 13,524/97; E. A. CAROLAN (*General Electric Co., U.S.A.*) [Automatic traction motor controller] 12,315/03; F. H. DE VEULLE [Multiple-way switch] 12,418/04; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Controllers for rolling-lift bridges, &c.] 11,536/05, and [Phase reverse cut-out] 11,626/05.

Telephony and Telegraphy: J. E. KINGSBURY (*Western Electric Co., U.S.A.*) [Telephone boxes for use on H.T. transmission lines] 11,336/05, and [Protective devices for telephones on tramway and railway systems] 11,337/05.

Traction: R. HADDAN (*U. Lachaud, Paris*) [Brakes] 11,555/99; V. I. FEENY (*Allgemeine Elektricitäts-Ges.*) [Motor supports] 11,163/01; J. A. BRILL [Car-body construction] 12,398/02; E. A. CAROLAN (*General Electric Co., U.S.A.*) [Automatic motor controller] 12,315/03; H. H. LAKE (*New York Air Brake Co.*) [Relief valves for brakes] 12,654/04 and 12,704/04; F. E. KINSMAN [Automatic brakes] 11,179/05; R. N. REDMAYNE [Third-rail insulator] 11,344/05; H. H. LAKE (*Duke-smith Air Brake Co., U.S.A.*) [Brakes] 11,510-9/05; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Electro-pneumatic multiple-unit control system] 11,537/05.

Miscellaneous: F. HUBBER and W. G. HIGGS [Fire-alarm system] 12,439/04; A. SCHEIBEL [Door alarm] 11,342/05.

THE MEETING OF THE BRITISH ASSOCIATION AT WINNIPEG

IN ELECTRICAL ENGINEERING, September 2nd (page 783), we published an abstract of the address of the President, Sir J. J. Thomson, and abstracts of some of the Papers read before the sections. We have now received a more complete report of the meeting from our Special Correspondents, and are able to give a further account of the proceedings and abstracts of some additional Papers.

SECTION G.—ENGINEERING.

On Thursday, August 26th, a Paper by Messrs. SMITH, KERRY and CHACE was read on—

The Hydro-Electric Plant for the City of Winnipeg.

The scheme was described by Mr. Chace with the help of wall diagrams, including the works now in progress of construction for obtaining power from the Winnipeg river at Point du Bois, and electrical transmission to Winnipeg City, a distance of 77 miles. The works were the object of a visit by the members of the section on Saturday 28th, when the suitability of the site was fully appreciated, and the preliminary work inspected.

The undertaking will consist, when completed, of the following:—A 60,000-h.p. generating station, operating under 45 ft. to 46 ft. of hydraulic head; a 77-mile transmission, consisting of four three-phase circuits carried on two series of double-circuit steel towers with concrete footings; a terminal station in the city, at which the pressure of the current transmitted will be reduced to 11,000 volts; an underground cable distribution to sub-stations; three or more sub-stations where the voltage will be reduced to 2,200 volts and 550 volts; and a secondary underground and overhead distribution to customers. At the generating station at Point du Bois there is a large lake adjacent to the head gates, with consequent favourable hydraulic conditions, and a contour favourable to economical works; the foundations are entirely of rock, and the difference of hydraulic level will be practically constant; also the water is free of silt, or other objectionable matter, either dissolved or in suspension.

After studying various possible designs, it was decided to build concrete overflow walls, a rock-filled dam, and a power-house with wheel pits built as an integral part of the head block, and a transformer station, also integral with the power-house itself. Further consideration of cost and climate gave as a result an enclosed forebay room, and double-runner turbine units of 5,200-h.p. capacity each, at a speed of 164 r.p.m., also motor-operated head gates protected by stop-log arrangements; the whole power-house being again protected by head gate piers in the canal, by which the canal can be unwatered by the use of stop logs.

The generating-room will ultimately contain two turbine-driven exciters, 250 kw. each, and two motor-driven exciters of the same capacity, and sixteen main generator units of 3,000 k.v.a. each, operating at 6,600 volts, 60 cycles, three-phase; of the above five main units and two exciters are to be now installed. These generating units will be so arranged as to be operative in groups of three per bank in accordance with a similar grouping of the step-up transformers. Electric travelling cranes of suitable capacity will be installed in the generator and turbine rooms. The generating station will be built throughout of reinforced concrete upon plain concrete tailrace walls.

The transmission system will be constructed upon a 100 ft. private right-of-way, and by the shortest feasible route. The towers are built up of structural shapes in an economical design and are of two types—braced, in which the speed of the base is about one-fourth the height of the tower), and flexible, consisting of channel irons supported in a plane normal to the axis of the wires; both types will be supported upon rigid concrete footings. Each line of towers will support two three-phase circuits of aluminium cable mounted upon pin-type insulators. A single circuit telephone line will parallel the transmission line, but upon cedar poles.

The terminal station in Winnipeg will receive power at 60,000 volts, and will deliver it to sub-stations at 12,000 volts, by means of a three conductor underground cable system. The transformers will be of the water-cooled type in both generating and terminal stations, but of the water-circulating class in the former, and of the oil-circulating type in the latter station. The high-tension bus-bar system in both stations will be of the open type. In both stations a very complete system of switching will afford the maximum of flexibility.

The discussion was opened by Professor E. G. COKER, who asked what efficiency was expected from the horizontal type of turbine employed at the head of 45 feet, and under the conditions of the scheme.

Professor E. W. MARCHANT asked why so high a frequency as 60 was used, leading as it did to large charging current and inductance drop, and what limited the voltage.

Professor W. M. THORNTON inquired as to the size of wire employed, the nature of the ground crossed by the line, what trouble they expected from lightning in summer and ice in winter.

Professor L. A. HERDT, of McGill University, one of the consulting board, replied that the choice of frequency was made chiefly because the supply would eventually enter territory already occupied by a power company, and would come into competition with it. The frequency of the supply now entering Winnipeg was 60. The choice was further limited by the fact that manufacturers refused to tender for frequencies between 25 and 60, which range he considered too great. He thought that some intermediate frequency would be more generally convenient. The lower frequency of 25 was ruled out on account of the high first cost of the plant. With regard to voltage this was determined very largely by capacity currents and the size of the units employed. Here they were using 3,000 k.v.a. machines, and at 100,000 volts they would have had to keep two of these running constantly to supply the line charging current. As it was they would have only one in use. The kilo-volt-ampere capacity of the line varied as the square of the voltage, and therefore they tried to keep the latter as high as possible. But in this scheme the size of unit was not so great that they could afford to raise the voltage from 66,000 to 100,000. If they had had 10,000 k.v.a. units, as at Niagara, it might have been done, but other considerations entered.

Mr. CHACE, replying to a question by Prof. Marchant, said that they were using the shell type of insulator. They had made tests in heavy rain, and found that with this type, made in four pieces, one of which is completely protected from the weather, 100,000 volts could be carried without any trouble. With regard to line drop, they specified an ample margin of field strength in the generators, and proposed to use automatic regulators. The machines were to have an inherent regulation of 18 per cent. With regard to the flow, the river had at that point 17,000 cubic feet a second. In front of the ice screen at the power-house the river expanded into a lake some five miles across. In consequence of this, no "ice-shove" was to be expected, this only taking place in confined river channels, as at Niagara. The line was of stranded aluminium 278,000 circular mils. (about $\frac{5}{8}$ in.). The poles crossed a peat swamp, and it was a bad line to run. The only trouble to be expected was from lightning; they used aluminium cell protective devices. The turbine was of the Francis type with radial and axial flow.

In the adjourned discussion, Mr. Chace said that the strands of the line were about $\frac{1}{4}$ in. diameter, and no brush discharge was expected with that large radius. In reply to Prof. Coker, Mr. Smith said that they anchored the reinforced concrete to be used to the rock, carrying the rods into the rock a distance of about eleven times their circumference.

At the meeting of the section on Monday, August 31st, the first Paper to be read was that by Prof. W. M. THORNTON and Mr. O. J. WILLIAMS on:—

The Distribution of Electric Stress in Three-phase Cables.

This Paper was given at some length on page 784 of ELECTRICAL ENGINEERING of September 2nd. The author gave in it the result of researches on the distribution of the stresses by the stream-line method employed by Prof. Hele Shaw and others in connection with other problems.

The next Paper of electrical interest to be read was one by Mr. E. A. WATSON, on:—

Atmospheric Loss off Wires under Direct-Current Pressures.

At the outset, the author remarks upon various theories developed from the corresponding effect of "corona" losses in alternating circuits, which would lead one to expect no such loss with continuous-currents. It is necessary to take into account the mechanical forces acting upon the disrupted air in virtue of its electrical condition, which tend to cause a motion of the air away from the conductor, a fresh supply coming up, to be broken down and driven away in turn. A rough calculation of the speed at which the disrupted air would be driven

Digitized by Google

away gives a velocity of about 10 metres per second. From experiments of Righi and others, it seems probable that the charge dissipated by the point is carried, not by the whole of the air contained in the corona, but by certain portions of it only, which move with a very considerable speed; their velocity has, indeed, been measured, and is given by Sir J. J. Thomson and others as 1·5 cm. per second for a field of 1 volt per centimetre. The charges appear to be carried by agglomerations of molecules forming a small part, perhaps 2 per cent., of the whole air surrounding the wire. The molecular clusters have attached to them electrical charges which impel them away from the wire at a speed depending upon the potential gradient. In their passage they may, under certain circumstances, but probably not in the case of a wire, push the whole body of air along with them, forming the "electrical wind" observed from charged points; this wind, however, is not the actual carrier of the charge, but is a secondary effort produced by the carriers.

Tests were made on a wire inside a concentric cylinder, and on two parallel wires.

In the first tests, which were to determine the effect of changes in barometric pressure upon the critical voltage at which loss commences, the wire was enclosed in a galvanised-iron cylinder, 8 in. diameter and 6 ft. long, which could be exhausted by means of a pump. The degree of humidity of the air was also under control.

The source of power was a large influence machine excited by an ordinary Wimshurst machine; across the terminals of the latter was connected a spark-gap with adjustable needle-point electrodes, the discharge from which kept the voltage of the "exciter" from rising above any desired limit. The excitation voltage was measured by an electrostatic voltmeter, with compressed-air insulation. The main generator would give voltages up to 70,000 volts; these were measured by an electrostatic compressed-air voltmeter connected across the terminals. From the machine, leads consisting of $\frac{3}{8}$-in. brass tubes were taken in the earlier tests direct to the testing apparatus; it was, however, found, that when this was done oscillations of voltage occurred, so that a steady voltage was not impressed on the wire. In the later tests, therefore, an arrangement of condensers across the machine terminals, combined with a high-resistance and inductance in the leads to the apparatus, was adopted, and this was successful in suppressing all the oscillations. The current flowing into the wire was measured by a reflecting microammeter, enclosed in a potential screen and mounted on a large 75,000-volt insulator.

Some difference was found to exist between the case where the wire was positive to the cylinder and when it was negative to it. When the wire was positive to the cylinder it appeared, if viewed in a subdued light, to be surrounded with a thin luminous film. If viewed in complete darkness, under certain conditions, the space surrounding the wire for a distance of 1 cm. or 2 cm. radially was seen to be full of fine branching bluish-purple brushes, darting about all the time and never remaining stationery on any point. The discharge made a slight hissing noise. When the wire was negative the luminous film was absent, but the wire was surrounded by a halo consisting of short, straight reddish-coloured discharges about 3 to 5 mm. long, practically stationary, and much brighter than the corresponding positive discharge. This discharge was accompanied by a loud hissing noise, plainly audible above the hum

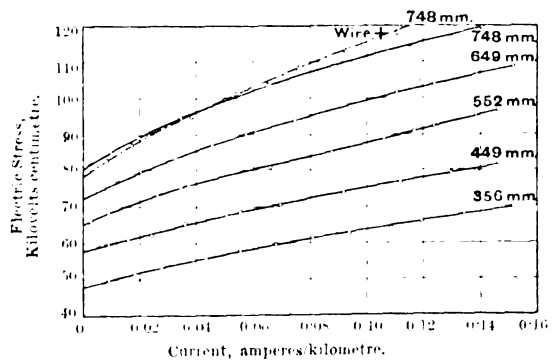

FIG. 1. LOSS CURVES FOR WIRE IN CYLINDER.

of the motor and influence machine. The negative corona was greatly affected by the presence of particles of dirt upon the wire. If the wire was dirty, the discharge seemed to concentrate itself upon the particles of dirt, from each of which a bright tuft of reddish light emanated not much longer, however, than the previous brushes from the clean wire. The discharge was much less noisy, and, in fact, if the wire were dirty enough, nearly silent.

With a perfectly clean wire, the negative corona appeared to require a slightly higher voltage to start it than the positive one.

The chief difference was in the voltage current characteristic of the discharge. When the wire was negative the curve was

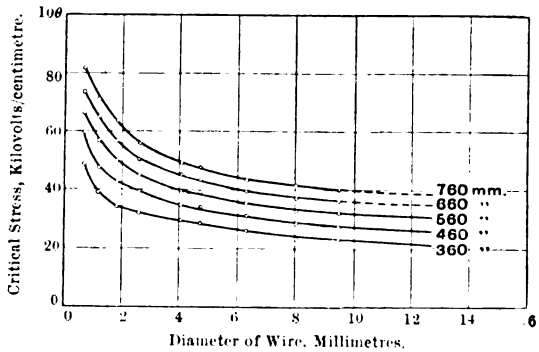

FIG. 2.—VARIATION OF CRITICAL STRESS WITH WIRE DIAMETER.

more nearly parallel to the axis of current than when it was positive *i.e.*, dI/dV was greater for a negative than for a positive corona. This can be seen on reference to Fig. 1, where the chain dotted curve is taken from a positive corona and the full line one from a negative.

Various other curves were taken for different diameters of wire. The most noticeable features of the series of curves are

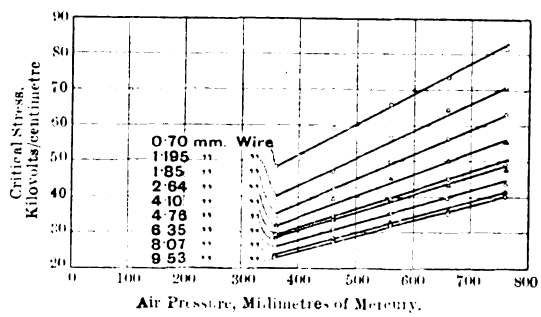

FIG. 3.—EFFECT OF AIR PRESSURE ON CRITICAL STRESS.

the increase of dI/dV with increasing wire diameter, and the decrease of electric stress required to start a corona. Of course, the actual voltage required to start the corona increased steadily with the diameter of the wire, but the electric stress due to this voltage steadily dropped from about 80 Kv.-cm. for the small wire to 40 Kv.-cm. for the large one. The rela-

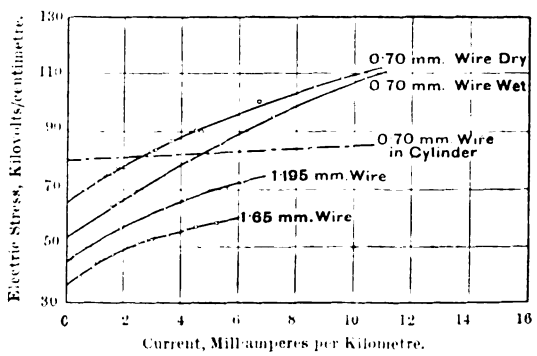

FIG. 4.—PARALLEL WIRES 1 METRE APART.

tion between critical stress and wire diameter for different atmospheric pressures is plotted in Fig. 2. It will be seen that the critical stress drops rapidly at first, but tends to get nearly constant for large wires. These results appear to agree well with those of Ryan.

It seems, therefore, fairly well established that the voltage of formation of the corona is very nearly the same, whether the stress be alternating or steady, provided that in each case the maximum value and not the root mean square be taken. One would not, therefore, expect it to be influenced by any change of frequency within the ordinary limits. The effect of changes in barometric pressure upon the critical stress is shown in Fig. 3.

Digitized by Google

The tests made upon two parallel wires were not so complete, as pressures sufficiently high to deal with wires of usual size could not be produced. The results with a 0·7 mm. wire show that the critical stress obtained from this test is considerably lower than was obtained from the tests on the wire in the cylinder, being for the wire, when dry, only 65 Kv.-cm., against 80. Two curves are given in Fig. 4 for the case when the wire was dry and when it was wet, which may be taken as representing the extreme limits between which the curves of loss may lie. The curves are not nearly as steep as those for the wire in the cylinder; in fact, the two curves cut one another, and although the loss of the parallel wire begins with a lower stress than the loss of the wire in the cylinder, yet for a loss of 10 milliamperes per kilometre the stress in the case of the parallel wire is the highest. From a theoretical standpoint it is practically immaterial whether a given electric stress be produced at the surface of a wire by placing it inside a small cylinder or at a much larger distance from another wire; the equipotential lines in the immediate neighbourhood of the wire will be the same in each case, and if these only determined the rate at which the ions were carried away, it should make no difference to the relation between stress at the surface of the wire and loss off it.

It is, however, very doubtful whether, once a corona has formed, the electrostatic laws do hold, as the air, being full of charged particles, cannot be expected to act as a true dielectric. It is, in fact, extremely doubtful whether the stresses shown in the curves as existing after the corona is formed really exist at all.

The author summarises his results as follows:—That there is a definite critical stress for which loss occurs from a direct-current line just as for an alternating-current one. That the direct-current stress required to produce this loss is the same as the maximum alternating-current one. That this stress is substantially the same whether the wire is positive or negative, provided that it is clean. That for dirty wires the electric stress is lowered much more for negative than positive charges. That the critical stress is greater the smaller the wire diameter. That the critical stress is reduced by reduction of the air pressure, but not proportionally. That the presence of water vapour in the air does not affect the loss or critical stress for a clean wire. That an actual transmission line does not behave exactly like a perfectly clean wire, but that a factor of safety varying from 1·5 to 2 should be allowed; also that the loss is affected by the presence of water vapour in the atmosphere, especially for low values of the electric stress, and that a considerable loss takes place before the wire is uniformly enveloped in a corona or becomes noticeably luminous.

A Paper by Prof. E. W. MARCHANT, D.Sc., was also read on:—

The Calculation of Charging Currents in Three-phase Cables.

The determination of the charging current flowing into any branch of a three-phase system cannot be determined by calculating successively and adding the charging currents which would flow due to the capacity between one part of the system and another, because the charges on the cores due to the various potentials of the different parts of the system are not in phase with each other, and that in determining the work done in carrying unit charge from one core to the other—that is, in determining the P.D. between two cores—corresponding with a given distribution of charges, the magnitude of the charges on the different conductors *at a particular instant* must be assumed and not the R.M.S. values of the charges. The author first considered the case of a three-wire overhead line, with the three wires arranged so as to form the three corners of an equilateral triangle, and deduced mathematically that the "effective" capacity per unit length is $\frac{1}{2\sqrt{3}\log_e \frac{D}{r}}$ in E.S. units, where D is the distance between centres and r the radius of each curve, and the R.M.S. charging current per kilometre $= \frac{Vp}{31{\cdot}18\times10^6\log_e\frac{D}{r}}$ amperes, where V is the R.M.S. P.D. between the lines in volts and $p = 2\pi \times$ frequency.

If we compare this result with the charging current that would flow in each line were two of them used for a single-phase installation and the other insulated, it is seen that the charging current with the three-phase supply is $2/\sqrt{3}$ or 1·155 times that with the single-phase supply.

The case of a cable with a capacity between the two cores C_1 and between each core and the sheath C_2, was then considered, and it was shown that the maximum value of the charging current flowing to each core is, therefore, given by

$$\frac{Vp}{\sqrt{3}}(2C_1+C_2) \text{ amperes,}$$

where V is in volts and C_1, C_2, are measured in farads. The same expression holds good for the R.M.S. value of the charging current, if V is taken to be the R.M.S. volts between the cores. The capacity determined by a ballistic test between one core and the other two connected to sheath is equal to $2C_1+C_2$, and if we call this capacity C, the charging current per line = star pressure $\times C \times p$.

If a star-connected three-phase alternator be coupled to a transmission line or three-core cable, there will be no component of the charging current of triple frequency, however large the component of triple frequency may be in E.M.F. wave. The E.M.F. wave, in all such machines, is similar in the three phases, provided the windings are symmetrical, and therefore there will be no component of triple frequency in the P.D. *between two lines*. This fact is of some importance, as it eliminates the risk of resonance with triple frequency. There may be large triple-frequency currents flowing along the line connecting a three-phase generator and a three-phase motor, both star wound, if the central points are connected to earth, but there can never be resonance on an overhead line. In a three-core cable, in which the neutral serves as the return, there is a charging current of triple frequency, but this is due simply to the capacity between each line and the sheath, and, in determining whether resonance is likely to occur with triple frequency, it is the capacity between the core and the sheath only that has to be taken into account. We know, further, that with a transmission line coupled to a mesh-connected generator or motor there can be no triple-frequency *current* in the line, and therefore with this connection there can be no resonance due to triple-frequency components of the E.M.F. waves of the generators. These results hold good not only for triple-frequency harmonics but for any harmonic whose frequency is a multiple of three times that of the fundamental wave.

All these three Papers were discussed together.

Colonel ANDERSON said that the figures and tables given by Prof. Thornton, if not of immediate use to the operating engineer, would be of great service to those concerned with the manufacture of electric cables, and they welcomed the very complete information given.

Prof. FEATHERSTONEHAUGH thought that Mr. Watson's Paper would clear up some points in long-distance transmission.

Prof. HERDT, in reference to Prof. Marchant's Paper, said that formulæ giving the charging currents of overhead lines differ by 20 per cent. That given by Prof. André Blondel, of Paris, includes the influence of the ground. Experiments on the Shawinigan power line at Montreal, a 16,000-volt 30-frequency scheme, agree very well with Blondel's formula. Other experiments at Toronto also confirm it. With regard to Mr. Watson's Paper, he said he had attempted at one time to measure the loss due to brush discharge, but had given it up. Mr. Watson's results were very valuable, but he thought that further experiments were wanted on long lines.

Mr. WATSON pointed out, in reply, that the brush-discharge voltage in a three-phase system would be lower than single-phase.

On Wednesday, September 1st, Prof. Featherstonehaugh read a Paper by Mr. OSMOND HIGMAN on:—

International Electrical Standardisation.

This Paper contained a detailed historical account of the inception and further proceedings of the International Electrotechnical Commission, with appendices giving particulars of its organisation and the work done regarding nomenclature and the new international standard of light, all of which has been dealt with in ELECTRICAL ENGINEERING from time to time.

Prof. THORNTON said that the Paper was of the nature of an interim report, and did not lend itself to discussion. He pointed out that the movement towards standardisation was much to the advantage of purchasers, who were enabled to compare quotations with some degree of certainty.

SECTION B.—CHEMISTRY.

There was very little of an electrochemical nature presented at the British Association meeting in Winnipeg, and what there was was mainly of a physical character. E. A. Archibald and W. A. Patrick read a Paper on the "Electrical Conductivity of Solutions of Iodine and of Platinum Tetra-iodide in Ethyl Alcohol." The conductivity of iodine was found to increase rapidly with time, and this was traced to the action of the platinum electrode. The report of the Committee on Electro-analysis, of which Dr. F. M. Perkin is secretary, was submitted,

Digitized by Google

and in it the work of Perkin and Sand published during the last twelve months was reviewed.

Dr. T. M. Lowry described a "New Method of Producing a Cadmium Arc." In order to produce a cadmium spectrum of sufficient intensity for polarimetric work, advantage is taken of the favourable properties of the silver cadmium alloys. On account of their isomorphism the two metals form an excellent series of alloys which are characterised by good mechanical properties and very high melting points. (An alloy with 60 per cent. of cadmium melts as high as 700°.) In striking contrast to the behaviour of the pure metal the alloy gives a steady arc, which can be kept true to centre by rotating the electrodes in opposite directions. The spectrum shows the silver as well as the cadmium lines. Dr. Charles Fox read a Paper on "Mercurous Sulphate for Standard Cells," an abstract of which appeared in ELECTRICAL ENGINEERING, September 2nd, page 786.

The same author also read a Paper on "The Constancy of the Hydrogen Gas Electrode." The constancy of the hydrogen electrode in sulphuric and hydrochloric acid with gold, platinum, and palladium electrodes coated with platinum and with palladium black has been investigated. Palladium coated with palladium black gives in both 1/10 normal sulphuric acid, and 1/10 normal hydrochloric acid, a value 4 to 5 millivolts too high, and this is permanent even when the hydrogen is passed over the electrode for hours. On the other hand, both gold and platinum coated with platinum or palladium black give, in a very few minutes, both in hydrochloric acid and sulphuric acid, values which are concordant among themselves to less than 0·05 of a millivolt. A piece of gold or platinum wire functions quite as well as a large piece of foil. Generally it is considered that the hydrogen-gas electrode in 1/10 normal hydrochloric acid is not so constant as in 1/10 normal sulphuric acid. But according to the author this does not appear to be the case, provided precautions are taken to exclude every trace of arsenic.

It is not possible to obtain a very good coating of platinum black on a very pure specimen of platinum foil if the platinum chloride solution employed is also very pure. For this reason a trace of lead acetate is usually added to the solution, but it is of the utmost importance to remove every trace of this from the electrode after coating, otherwise good values cannot be obtained.

The Incorporated Municipal Electrical Association.—We have received a copy of the Proceedings of the Association for 1909, which contains a full report of the Papers and discussions at the fourteenth annual Convention, held last June at Manchester, the annual report and accounts of the Association, and a special report by Mr. E. Lunn, the holder of the Association's travelling studentship.

The Paris Telephone Service.—According to the *Times*, M. Millerand, the new Minister of Public Works, is elaborating a scheme for the complete reorganisation of the telephone service in Paris at a cost of £4.000,000. The Chamber of Commerce, the Municipal Council, and the Conseil Général will, in M. Millerand's scheme, be called upon to assist the State in providing for the improvement of the service. The difficulty has been that it was impossible to diminish the telephone charges simply because a serious increase in the number of subscribers was feared, and the existing organisation is incapable of satisfying even the present subscribers. The present annual charges are £16. With the new scheme it is proposed to lower them t £12.

Automatic Level-crossing Gate.—An electrically-worked automatic crossing gate is in use on the Montreux-Berne-Oberland electric railway, near Montreux, Switzerland. According to the *Railway Gazette*, the long pole-like barrier is pivoted on a cast-iron bracket, which is attached to an iron column, and carries all the driving mechanism, including the motor, resistance coils, &c. The motor drives a large gear-wheel on a horizontal axis fitted to a conical drum, with a spiral groove for winding a cable. The end of the shaft serves as the suspension point for one end of this cable, which passes around a pulley on the short end of the bar. Below and parallel to the axis of the drum is a spring brake. The barrier is a channel iron with a light wooden extension. Its short end carries a counterweight of cast-iron. The cable crosses the track (overhead) on pulleys and operates the swinging bar on the other side. Lamps and a bell are used as signals. The current for the bell, lamps, and motor is supplied through the contact of the bow trolley with an auxiliary wire paralleling the trolley wire. The proper length of this wire depends upon the usual speed of the train at the crossing. When the bow trolley comes in contact with the wires, the auxiliary wire is connected to the line, and the resulting current operates the motor, lamps, and bell. The motor is series wound and takes about one-tenth horse-power, running on 120 volts at 400 r.p.m. The operation of the bar requires about 20 seconds. Before it has completely reached the horizontal position the cable winds upon the conical part of the drum, and this retards the motor, and the bar is brought gradually to rest. While the bar remains closed the current continues to traverse the motor, and is not interrupted until the bow trolley leaves the auxiliary wire. Then the counterweight acts to bring the bar to the vertical position.

A NEW METHOD OF ARTIFICIAL RESPIRATION

A USEFUL wall sheet is being issued by the Royal Life Saving Society, giving illustrated directions to be observed in cases of apparent death from electric shock. The instructions, which are in accordance with the Schäfer method, are simpler than those formerly in use. After giving directions for freeing the patient from contact with the live wire, directions are given for artificial respiration as follows:—

Place the body on a dry floor or table, or dry straw, and, if no sign of breathing can be observed, immediately proceed to promote artificial breathing.

1. Turn the patient face downwards. (*See Diagrams.*)
2. Kneel at his side and place your hands flat in the small of his back with thumbs nearly touching and the fingers spread out on each side of the body over the lowest ribs. (*See Diagrams.*)
3. Then promote artificial breathing by leaning forward over the patient and without violence, produce a firm, steady, downward pressure. (*See Diagram marked "Expiration."*) Next release all pressure by swinging your body backwards without lifting your hands from the patient. (*See Diagram marked "Inspiration."*)
4. Repeat this pressure and relaxation of pressure as directed in clause 3, without any marked pause between the movements, about fifteen times a minute, until natural breathing is established.
5. The efforts to restore breathing must be carried out with perseverance, as life has been restored after a long period.

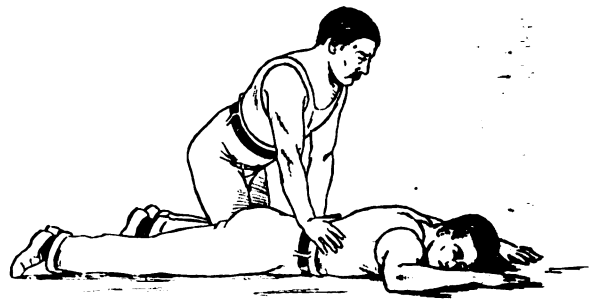

FIG. 1.—EXPIRATION.

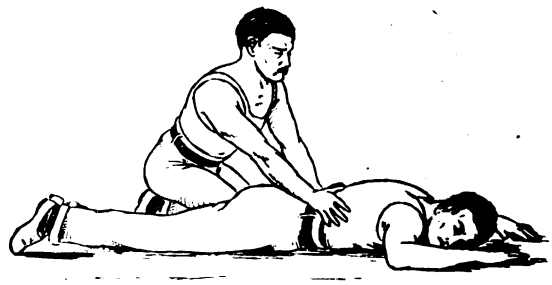

FIG. 2.—INSPIRATION.

Medical assistance should be sent for as soon as possible in all cases, and stimulants should not be administered unless recommended by a medical man.

The charts are supplied by the Society (8 Bayley Street, London, W.C.) at 6d. per pair, post free, and a handbook explaining a special drill is also issued by the Society.

High-frequency Generator.—A patent has been applied for by R. A. Fessenden, for a machine for generating high-frequency currents for wireless and other work. It comprises a large disc of phosphor-bronze or nickel-steel in the periphery of which are cut a large number of slots. These slots are filled up with thin iron sheet, and, when the disc is rotating, vary the reluctance of magnetic circuits comprising poles arranged on either side of the disc round the periphery and joined by yokes. One exciting coil external to, and in the plane of, the disc, magnetises all the circuits. The high-frequency currents are generated in coils arranged on the poles. To rotate the disc, wound radial armatures are provided on both sides of the disc, concentric to the outer poles. The windings of these armatures are supplied with a two-phase current with a frequency of 500 cycles per second, and the disc is driven by the reaction of the eddy-currents induced in it. It is stated in the specification that the disc can be conveniently run at a speed of 30,000 r.p.m.

IRONCLAD FUSE BOXES ON THE UNIT SYSTEM

OF recent years ironclad distribution boxes have been almost universally adopted for power work, in place of the older forms of teak case boxes. The use of cast-iron cases for distribution fuse boxes has, however, always been open to the objection that extensions were not easy to make. In the design of a large power installation it has been necessary either to provide spare-ways on all distribution boards to cover future extensions, or, when extensions were required to be made, to take down the existing board and erect one of a larger capacity, thereby disarranging the supply of a number of motors and delaying and upsetting work.

The Hope's unit system has been introduced by Messrs. Parmiter, Hope & Sugden, of Hulme Electrical Works, Manchester, to overcome this difficulty. In this system the cast-iron cases are built up in such a way as to allow of either end being removed and an additional case unit being added, the box remaining perfectly watertight and gastight. Four strong set screws hold the cases, or end plates, as may be, together: additions can therefore be made in a few moments. All the parts are "jig" made throughout, and it is guaranteed that all extension pieces will go together without any filing or fitting whatsoever. With regard to the interior, each fuse-way is a separate unit complete in itself; the fixing of the bases and coupling up of the same to the 'bus-bars is done entirely from the front of the board, and extra fuse-ways can be coupled up from the front of the case, whilst the board is "live." All the bases are of black china, and the insulation test of any complete board is guaranteed to be at least 50 megohms.

The accompanying illustrations explain the system. The appearance of two units coupled up, and with the lids closed, is shown by Fig. 1, while Fig. 2 shows the interior view of a single unit. Fig. 3 is a view of the same unit dismantled, showing the method of construction, and Fig. 4 is an interior view of the coupled units. It will be noticed that the board illustrated in Fig. 4 is a six-line board, with provision made for two extra ways, to be added later. The drilling is already complete, so that the extra ways can be added in a few minutes. The units are made single-pole only, so that two units must be allowed for double-pole, and three for triple-pole fuse-boards.

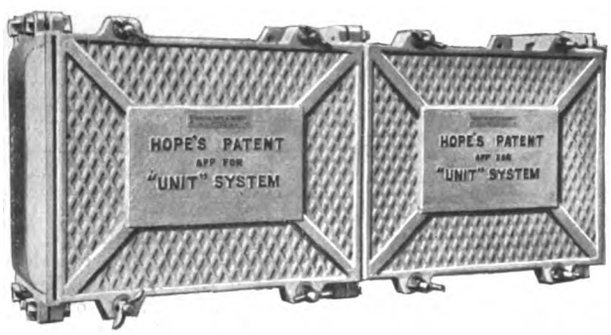

FIG. 1.—TWO-UNIT BOARD—CLOSED.

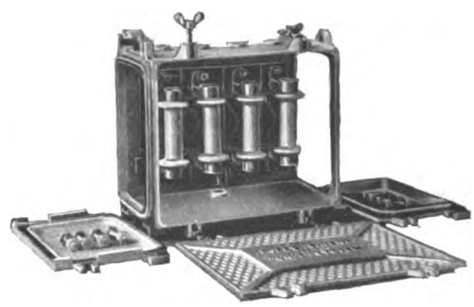

FIG. 3.—DISMANTLED UNIT.

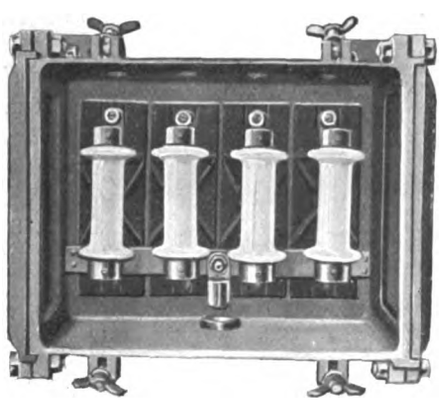

FIG. 2.—INTERIOR VIEW OF UNIT.

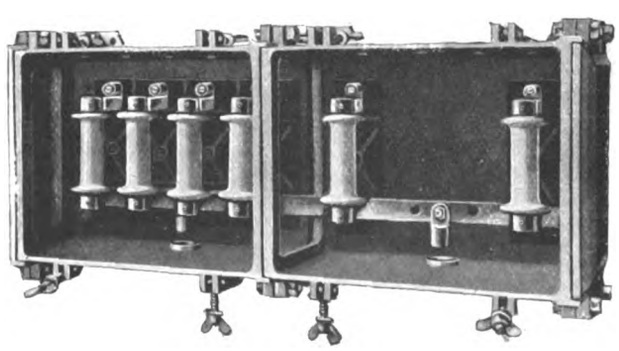

FIG. 4.—TWO-UNIT BOARD—OPEN.

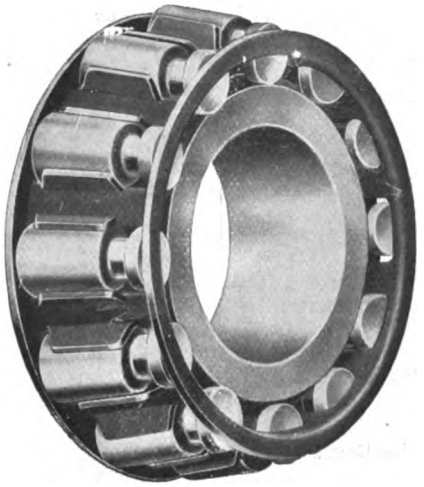
The Electrical Contractors' Association and Municipal Wiring.—In the Aberdeen Sheriff Court on Wednesday, September 8th, a petition for interdict was presented at the instance of the Electrical Contractors' Association of Great Britain, against the Town Council of Aberdeen. The complaint of the pursuers is that the defenders have contravened the wiring section of the Aberdeen Corporation Electricity Act, 1907, in respect that they have laid cables in the grounds of the Aberdeen City Hospital, and have wired several buildings in the grounds. Sheriff Begg ordered intimation of the petition to be made to the defenders, and notice of appearance was to be lodged within five days.

The Association of Engineers-in-Charge.—The Council of the Association of Engineers-in-Charge have elected Mr. Henry Adams, M.I.C.E., as their President in succession to Mr. James Swinburne, F.R.S., M.I.C.E. Mr. Adams is one of the oldest members, having so far back as 1865 been in responsible charge in the outdoor department of Sir W. C. Armstrong and Co.'s Elswick Works.

Sheffield Corporation Water Tunnel.—According to *The Times*, the Sheffield Corporation's tunnel through the Bamford hills for bringing water from the Derwent Valley into the city was cut through on Sept. 11th. It is over four miles long, and has taken over five years to construct. During the progress of the work the tunnel has been ventilated by electric fans, and all the material has been drawn out by electrically-hauled trucks.



The Automatic Telephone Exchange in Germany.—Mr. W. W. Brunswick, U.S. Vice-Consul at Chemnitz, states that the first automatic telephone exchange installed by the Imperial German Post Office in Hildesheim is working successfully, and that the Government is energetically pursuing experiments.

New Water-power Plant in Mexico.—The Guanajuato Power & Electric Co., of Mexico, is erecting a third water-power station, which, when completed, will bring the total available electrical power of the company up to 21,000 h.p. The first plant erected was that at Zamora, which has a capacity of 8,000 h.p. The second plant was built at El Sabino. Electrical energy is transmitted from these stations at 60,000 volts over a line carried on steel towers to Guanajuato, 120 miles distant. From here the energy is distributed at 15,000 volts to the surrounding districts, more than 50 miles of distributing circuits being necessary to reach the company's customers. Steps are now being taken to construct 30 additional miles of circuits. The site chosen for the third plant which the company is preparing to erect is seven miles above Brunel on the Angula River. The new plant will have a rating of 10,000 h.p. The cheap energy furnished by the company has led to the development of many mines in the Guanajuato district, and has been of great benefit to agricultural and manufacturing enterprises. The energy is used to operate irrigation pumps in places within a radius of 150 miles of the power plants.

ROLLER BEARINGS

A PATTERN of roller bearing particularly suitable for the road-wheels of automobiles, &c., has been introduced into this country by the Electric & Ordnance Accessories Co., Ltd. (Cheston Road, Aston, Birmingham). This bearing is known as the "Timken" patent roller bearing, and has met with much success in Canada and America. The above British company has secured the sole manufacturing and selling rights for Europe and the British colonies (with the exception of Canada), and will shortly commence to manufacture at its works at Aston. This bearing can also be used in electric motors, hangers for line shafting, and for other purposes, its principal features being the long bearing surface, as compared with a ball bearing, its ability to withstand as much end thrust as radial load, and the ease with which any wear can be adjusted, owing to the cone shape of the bearing.

INNER CONE, CAGE, AND ROLLERS OF THE "TIMKEN" ROLLER BEARING.

The accompanying figure illustrates the construction of the bearing. As will be seen, it comprises an inner cone with two ribs, one of which engages the grooves in the small end of the tapered rollers. The large ends of the rollers are grooved or flanged, and press up against the other rib on the inner cone, and the whole slides into an outer cup or race-way with a smooth inner conical surface not shown in the figure. The ribs prevent the rollers from twisting and turning crosswise on the cone, and take up the end thrust. The rollers, in revolving, roll on the ribs and do not slide, thereby reducing the end thrust friction to a minimum. The contact between the rollers and the cones, however, is entirely on the surfaces between the ribs, and the grooves in the rollers do not press on the ribs of the inner cone. The pressed steel cage ring, visible in the figure, retains the rollers in position, ensuring good alignment and holding the lubricant. Wear of the bearing is taken up by forcing the inner cone with its rollers further into the race-way. Dimensions, safe loads, and further particulars of these bearings are given in the catalogues issued by the Electric & Ordnance Accessories Co.

Telephones in Turkey.—According to an American Consular report, an American company is endeavouring to obtain the telephone concession at Constantinople, either to work it themselves with provision for its subsequent purchase by the Government, or else to instal the plant for the Government. An electric company is also working to secure the telephone concession of the entire Ottoman Empire, as well as of Constantinople, offering to instal telephones in all cities of over 100,000 inhabitants and wherever more than a certain number of subscribers could be found, and is ready to effect a considerable outlay for this purpose. It has not yet been decided as to whether the telephones should be given to private enterprise or exploited by the Department of Posts and Telegraphs.

British Electrical Trade with Chile.—According to a British consular report, the imports of electrical machinery and apparatus from the United Kingdom increased very much between 1905 and 1907. Whereas some 150 tons were imported in 1905, the amount in 1907 was 1,400 tons. The corresponding figures for German goods are 555 tons and 1,500 tons respectively; for the United States, 345 and 454 tons; and for those of other countries, 15 and 44 tons respectively.

Electrical Manufacture of Nitrates from the Atmosphere.—A British consular report states that there is now in Germany plant, either in full working order or nearly completed, capable of producing over 40,000 tons of nitrate of lime per annum. New works are being erected in Bavaria, and a factory has just been built in the Tyrol by a Westphalian company, which is capable of producing about 3,000 tons of nitric acid, and from this a corresponding quantity of nitrate of lime. It is estimated that about 1,300 tons of nitrate of lime were sold in Germany in January and February last. At this rate, the sales for the whole year will amount to over 7,500 tons, or about 1½ per cent. of the total quantity of natural saltpetre annually consumed in the country.

DEVELOPMENTS ON THE THURY D.-C. SYSTEM

OWING to the success of the well-known "Series" direct-current transmission line from Moutiers to Lyons, which has been in operation since 1905, some important developments are to be carried out on the same lines. The generating station itself is situated near to Moutiers (Savoy), and takes its power from the River Isere. The generating plant includes both high-tension direct-current machines and high-tension alternators. The total horse-power of D.-C. high-tension plant at present is 6,400, and is transmitted at a pressure of 57,000 volts to Lyons, a distance of 180 kilometres, by means of two conductors of 9 mm. diameter. Parallel to the continuous-current line is a three-phase line going to the same point. At Lyons the D.-C. energy is utilised in a number of motor-generators.

The series system has not only demonstrated its elasticity, but has proved to be so reliable and easy to operate that the companies have decided to carry out extensions on a large scale. A generating station is to be erected at La Bridoire (Savoy), in which three generating high-tension D.-C. units will be installed, each of 2,000 h.p. at 428 r.p.m. They will work at a current density of 150 amps., a pressure of 8,000-9,125 volts.

A second generating station on the Roziers, at Bogel (Savoy), will contain two generating groups each consisting of two double machines driven by the same turbine, and capable of an output of 3,500-4,000 h.p. at 428 r.p.m., and delivering current at a density of 150 amps. and a pressure of 16,000-18,250 volts. A corresponding amount of D.-C. motor-generator plant will be placed in the Vaulx-en-Velin sub-station. The total capacity of the direct-current high-tension generating plant, when the extensions are complete, will be 15,000 kw., and the three generating stations connected in series will deliver 150 amperes at 100,000 volts. This will be a notable development, as for the first time in Europe an operating voltage of 100,000 volts will be reached, and it is claimed that this pressure is not the limit which can be achieved on this system.

THREE-PHASE ALTERNATORS FOR 17,000 K.V.A.

THE A.G Brown, Boveri et Cie., of Baden, Switzerland, has recently obtained one of the largest orders for electrical generating plant ever placed in Europe. This consists of five three-phase generating units, each rated at 17,000 k.v.a. (at 0·6 power factor) at 10,000-11,000 volts and 50 cycles, with direct-coupled exciters of 130 kw., for coupling to water turbines of 14,000 h.p. at 250 r.p.m. This generating plant will form one-half of the power equipment of the new generating station now being built for Messrs. A. S. Rjukanfos, of Christiania, for the production of saltpetre from atmospheric nitrogen, which station, when completed, will be the largest in the world. Messrs. Brown, Boveri & Co., Ltd. (London), to whom we are indebted for the foregoing particulars, in referring to the extremely severe character of furnace-work of this description, mention that the weight of one of these generators is about 200 tons, the diameter being nearly 20 ft. They add that the above order was obtained in competition with the leading firms of the Continent, and that it was settled upon the technical merits of the designs and not upon considerations of price; and further, that the A.G. Brown, Boveri et Cie. has no financial interest whatever in the undertaking.

Electrically-driven Excavators.—A description of two 110-ton excavators recently built for the Dolese & Shepard Co., of Chicago, for mining rock in its limestone quarries, is given in a recent issue of the *Electrical World*. These have buckets holding four cubic yards of material, and are equipped with Westinghouse motors and automatic control. The hoist movement of these machines is effected by a 200-h.p., 220-volt, series-wound D.-C. mill motor running at 415 r.p.m.; the thrust motor, controlling the movement of the dipper handle, is an 80-h.p. machine of similar type; while the swing boom is operated by an 80-h.p. motor. Each motor is controlled independently by an automatic magnetic switch controller. This form of control protects the motors from any heavy overloads which may result from the bucket striking solid rock or other obstructions, by opening switches to introduce resistance into the motor circuit. The control panels and resistances are mounted in the rear of the cab, while the controller handles are conveniently placed under the hand of the man in charge. The hoist and swing-boom motors are mounted within the car. The thrust motor is placed out on the boom, communicating its motion to the bucket staff through reducing gearing connected to a pinion engaging a rack on the staff. The supply to the excavator is completed through a cable, carried on a retractile reel on the cab, and through the rails on which the excavator advances. Compared with the steam navvy, the electrically-driven excavator has been found to present marked advantages of simplicity, economy, and ease of working. The hauling of water and coal is avoided, fewer men are required to handle the machine, and a considerable saving of time is noted.

A NEW ELECTRIC SAFETY LAMP

At the meeting of the Institution of Mining Engineers in Newcastle last week, Mr. J. G. Patterson, of Darlington, exhibited an interesting electrical safety lamp with some rather unique features. In consisted of a metallic filament lamp placed in front of a strong parabolic reflector and behind a glass lens, so that a beam of 20 candle-power measured along the focal axis is obtained. This is operated from a four-volt cell contained at the base of the lamp. In conjunction with this, however, at the back of the lamp is a small oil lamp protected both with a glass shield and a piece of gauze, which is intended for testing for gas in the usual way. A switch is arranged whereby the light from the electric lamp can be turned off, and simultaneously a current is passed through a platinum wire by means of which the oil lamp is ignited. In order to prevent both oil lamp and electric light glowing simultaneously, when the latter is switched on, a snuffer over the oil lamp is brought into operation, so that they cannot both burn at once. Moreover, in a gassy mine, an arrangement is supplied on the lamp for shutting off the air supply to the oil lamp in order to extinguish the flame. The weight of the whole equipment, which is intended to burn from 14 to 20 hours continuously, is only 5 lbs., and, in view of the recent Mines Act, it is possible to produce a lighter lamp to burn for an eight-hour shift.

WIRELESS TELEGRAPH NOTES

In the House of Commons on Monday Mr. Henniker Heaton asked the Postmaster-General what steps he proposed to take for the prolongation of the Wireless Telegraphy Act, renewed in 1906 for a term of three years, and also whether, in view of the rapid developments in the practical application of wireless telegraphy, the interests involved, and the negotiations now proceeding for the acquisition by the Post Office of important existing installations, an opportunity will be afforded for a full consideration of the act before the end of the present session. He also asked what new conditions had arisen since the last renewal in 1906, which might render it expedient to depart from the practice hitherto followed of renewing the Act for a specific limited period. Mr. Buxton, in a written reply, stated that it was proposed to renew the Act to the end of next year, and that as the Act had been renewed once only, it could not be said that there was any recognised practice as to the manner of its renewal. He added that there appeared to be no need at present to revise the Bill, and that no question had yet arisen which necessitated any alteration in the Act.

The Compagnie française de télégraphie sans fils, founded in 1906 by M. Victor Popp, the inventor of the system which it instals, has made considerable progress in France, Spain, and Morocco. The company has a capital of 1,670,000 frs., which is to be raised shortly to 2,500,000 frs. It has supplied the equipments for the Black Sea coast stations of the Roumanian Government, and erected also the stations at Tangier, Casablanca, Rabat, and Mogador, which are now open to public service. The company has also secured a concession for twenty-two years, dating from October 1st next, for the erection and working of wireless stations in Spain, the Balearic Isles, and the Canary Islands. The following stations will be erected shortly: Stations at Cadiz and Teneriffe, with ranges of 2,500 km.; at Las Palmas (Gran Isle, Canary Islands), with a range of 5.000 km.; and at Cape Finisterre and Barcelona, with ranges of 1.200 km. The stations in the Canary Islands will communicate with ships on the routes to Africa and South America, and will send them the principal exchange quotations twice every day.

A wireless station has just been erected at Willemstad, the capital of the Island of Curaçao, in the West Indies, belonging to the Dutch Government.

British Electrical Trade with Spain.—A British consular report for the district of Bilbao for the year 1908 states that there is still a tendency for orders for heavy electrical plant to go elsewhere in preference to the United Kingdom. Whereas some 52 tons of electrical machinery and fittings were imported into the district from the United Kingdom in 1907, the same figure for 1908 is only 26 tons. The importation from other countries has fallen also, however. The corresponding figures for Germany are 331 tons in 1907, and 304 tons in 1908; and for Belgium 250 tons and 148 tons respectively.

Electrical Manufacture of Nitric Acid and Nitrates in the Transvaal.—According to an American Consular Report, a new company, known as the Pretoria Power Co., is being formed to supply electric power, and to manufacture nitrate of lime and nitric acid from the atmosphere at a large water-power station on the Crocodile River, Transvaal. Three large banks in Europe are said to be supplying the capital. For the initial works, which are to furnish 20.000 to 25.000 h.p., £700,000 will be required, and for the nitrate of lime and nitric acid works a further £250,000 will be necessary. The present cost of nitrate of soda delivered to South African ports is about £11 per ton, while nitrate of lime, which serves the same purpose as a fertiliser, can be produced and sold, it is said, at half that price in the Transvaal. There is also a considerable demand for nitric acid in South Africa for use in the manufacture of dynamite for mining purposes.

SAFETY PRECAUTIONS IN MINES

During the meeting of the Institution of Mining Engineers at Newcastle last week, Messrs. A. Reyrolle & Co., Ltd., of Hebburn, gave a demonstration of considerable interest in connection with Mr. Robert Nelson's Paper.

One of the chief objects of interest was a box-type iron-clad switchgear, which has been produced to supply the demand for a cheap form of dust-tight apparatus for controlling motor circuits and distribution boards in mines. The switches and transformers are made readily accessible by opening a large door in front. This access is made safe by an interlocking arrangement which prevents the door from being opened unless the isolating switch at the top is also open, and, therefore, access can only be obtained to the working parts at times when they are absolutely safe to handle. Moreover, it is impossible to close the isolating switch again until the door has been closed. The drum-type starter, which has been designed for controlling an air compressor or coal-cutter in places in mines where Rule 8 applies, was also shown. In addition to being hermetically sealed (even the push-button for the release of the switch has an air-tight flange), the casing is provided with an extremely broad flange. The object of this is that, should an explosion occur within the box due to gas or possible coal dust, the gases of combustion are sufficiently cooled by the broad surface of metal over which they would have to force their way to such an extent that they are below the temperature of ignition when they reach the outside air. A special demonstration was arranged to show this by which one of Messrs. Reyrolle's new boxes was contrasted with an ordinary type of case in which the joint was protected by means of a rubber ring. Coal gas was admitted from the town mains and exploded in the boxes. In the case of the ordinary box a sheet of flame was perceptible on the outside, which would, of course, involve a wholesale explosion in a mine, whereas in the Reyrolle box, although a disturbance of air was apparent, there was no flame.

Another exhibit was that of a 30-ampere three-phase oil break switch for mine purposes. This switch contains in one apparatus provision for properly receiving three-core or single cables, automatic no-voltage release, and overload release. The whole apparatus can be, when required, enclosed in an explosion-proof casing to make it available for places where Rule 8 applies. Wherever possible this apparatus is recommended in preference to the use of a combined switch and fuse, as greater safety is afforded on account of the suppression of the arc under oil. A 150-ampere three-phase oil break switch of the same type, but on a large scale, was also on exhibition.

A demonstration of the Merz-Price core-balancing system of protection was also given, designed to give an instantaneous isolation of a fault to earth, thus tending to relieve the risk of dangerous flashing on a faulty cable.

The demonstration was well attended by members of the Mining Institute, and very great appreciation was expressed as to the quality and ingenuity of the designs exhibietd. This, together with the impressive nature of the electrical equipment at Harton Colliery, which was visited, did very much to counteract the feeling of apprehension which has arisen in some engineers' minds with regard to the use of electricity in mines.

PEKIN TELEPHONE SYSTEM

As already announced in our columns, the Western Electric Company, of Chicago, has obtained, through its agents in China, the Armhold Karlberg Co., of Tientsin, the Chinese Government contract for the establishment of a telephone system in Pekin. The amount of the tender was $150,000 (approx. £30,000), and the contract provides that the equipment shall be completed by February 3rd, 1910. The installation will be under the supervision of American engineers until the Chinese operators have thoroughly mastered the working. According to the American *Electrical Review and Western Electrician*, two exchanges on the common-battery system have been ordered, but this is considered as but the beginning of a system that will eventually be fully developed throughout China. Hitherto almost nothing in the way of telephone development has been accomplished in China. There have been telephones in only a few of the cities, and these largely in the foreign quarters, which were served by small out-of-date systems. The two switchboards sold by the Western Electric Company to the Government are the first common-battery boards in the entire Empire. The Board of Communications not long ago formed what was known as the International Chinese Telephone Administration, and Mr. F. M. Dresing, foreign adviser of this body, visited the Western Electric Company while on an American tour last autumn. Chinese commissioners visited America, inspected the telephone plants of the large cities, and were shown through the shops of the large telephone manufacturers. The Western Electric Company sent a special emissary to Pekin, and the result of his efforts has just been announced. The order covers a complete telephone plant of the most modern type, including several hundred thousand feet of lead-covered aerial and underground cable.

COMMUTATION-POLE TRACTION MOTORS

ONE of the latest novelties in electric traction has been the introduction of motors fitted with special commutation poles. For many years after the design of standard railway motors was worked out it was considered that a final form had been arrived at on which any substantial improvement was a practical impossibility. It is true that the motor was by no means sparkless under certain conditions, but it was generally considered that the amount of sparking experienced in actual practice was unimportant, and that any measures that could be taken to overcome the trouble would be worse than the disease.

Quite recently, however, large railway motors have been designed both for standard voltages and also for high voltages, in which it was considered advisable to make special provision against sparking by the introduction of commutation poles. The results obtained with these motors were found to be so satisfactory that it was considered worth while to apply the experience so gained to the construction of tram-car equipments. In this way a complete line of motors of this type has been evolved for outputs ranging from 22½ h.p. up to 150 h.p., and even larger units have been designed with outputs up to 250 h.p. For the smaller motors a special design has been worked out

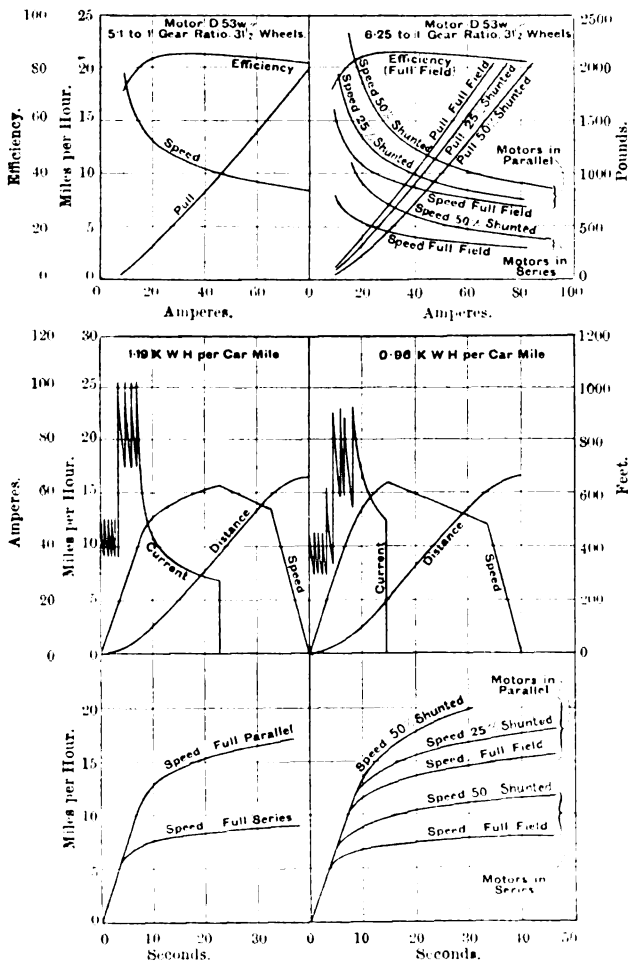

FIG. 1.—PERFORMANCE CURVES FOR CAR EQUIPPED WITH TWO 38-H.P. INTERPOLE MOTORS.

(the patent rights for which are held in this country by Messrs. Siemens Bros. Dynamo Works), by means of which the introduction of commutation poles causes very little extra expense and very little increase on the overall dimensions of the motors. The special feature of this design will be referred to subsequently. The most obvious benefit gained by the use of commutation-pole motors is freedom from sparking and the consequent decrease in the cost of maintenance due to this cause. This property is especially valuable in cases where there are steep gradients. It is only necessary to state that the motors fitted with commutation poles will run without the slightest sign of sparking at any output up to 50 per cent. overload for the importance of this advantage to be fully realised.

This, however, is by no means the only advantage, and in many cases it is not the most important. Traction motors of the ordinary type without commutation poles are naturally sensitive to sparking, and for this reason the early attempts at some degree of control by varying the strength of the field in relation to the armature current were practically abandoned. As soon, however, as motors were introduced in which there was no fear of sparking, even when 50 per cent. of the field current was shunted, the objections urged against this method of control were no longer valid. Messrs. Siemens Bros. Dynamo Works are now putting on the market a controller in which provision is made for shunting the field windings in varying degrees as may be suitable for any particular case, such, for example, as 25 per cent. and 50 per cent. In this way a controller is arrived at in which, instead of there being as usual two economical running positions, namely, full series and full parallel, there are at least five, for example :—(1) Full series full field; (2) full series field shunted 50 per cent.; (3) full parallel field shunted 25 per cent.; (4) full parallel field shunted 25 per cent.; and (5) full parallel field shunted 50 per cent. This system of control offers the important advantage that the driver has a more complete control over his car, having the choice of five different speeds under any given conditions. A considerable economy in consumption of energy is also made possible.

In order to illustrate these advantages the curves shown in the accompanying figures have been prepared. These curves relate to a 10-ton tramcar, equipped with two 38 h.p. commutation-pole motors. Two sets of performance curves for these motors are given, one for the motor geared with a reduction of 97 : 19, and the other with a reduction of 100 : 16, the diameter of the driving wheels in each case being 31½ in. In the first case the speed and pull curves are given for the full parallel position of the controller, in the second case speed and pull curves are given for the five running positions of the controller. With these two sets of curves a sample run has been worked out as shown in the diagrams, in accordance with the following particulars :—

Tractive resistance, assumed to be constant, 20 lb. per ton.
Number of stops per mile, 8.
Average speed, including five second stops, 10 miles per hour.
Maximum speed, about 16 miles per hour.

The energy consumption has been worked out, with the following results :—

With fields not shunted, 1·19 kw.-hour per car mile.
With fields shunted, 0·96 kw.-hour per car mile.

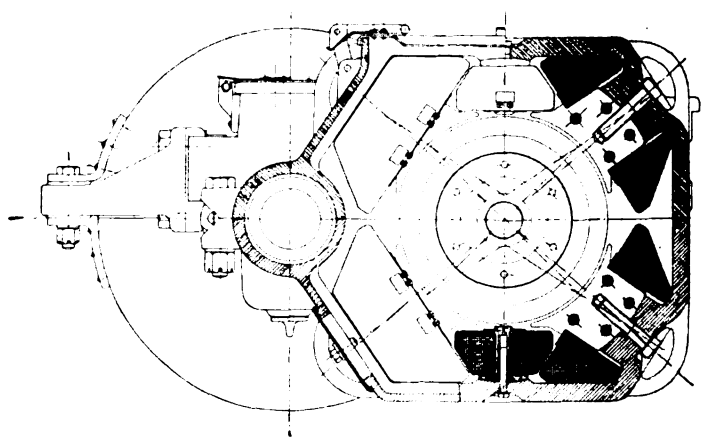

FIG. 2.—SECTION OF MOTOR, SHOWING POSITION OF COMMUTATING-POLE WINDINGS.

In this particular case, therefore, the change of gearing and the different method of control makes possible a saving of about 20 per cent. in the energy consumption. This may possibly be regarded as an extreme case; but the matter may be put in another way. The energy imparted to the car between standstill and the time when it reaches a speed of 12 miles per hour is in the one case 82 watt-hours, and in the other case 68 watt-hours, so that on the assumption that this is repeated at regular intervals of 45 seconds, that is, 80 times per hour, the energy saved per car during that hour is 1·12 kw. Thus, quite apart from the question of the energy absorbed by the brakes, which may vary according to the particular circumstances of the case, there is a clear saving of 10 per cent. of the energy consumption in imparting to the car a speed of 12 miles per hour.

The flexibility of the modified system of control by means of shunting the fields is clearly seen in reference to the remaining curves, which show speed time curves for the two cases. In the first case there are only two speed time curves, namely, that in which the motors are in full series and that in which the motors are in full parallel; in the second case there are five speed curves, corresponding to the five running positions of the controller. The comparison between the two sets of curves requires no explanation. The degrees of shunting assumed for the purpose of this calculation are not necessarily

Digitized by Google

fixed, but may be modified to suit each particular case for which the equipments are desired.

Referring now to the construction of the motor, the general features of the design worked out especially for tramway motors are shown in section in Fig. 2. It will be seen that there are the usual four main poles, and in addition two commutation poles, one between the main poles in the upper half of the motor, and the other between the main poles in the lower half. In order to provide as much room as possible for these commutation poles and their windings, the main poles are given a special shape such that the magnet coils are not symmetrical about the centre lines of the poles, but are displaced sideways. The pole faces, however, are spaced symmetrically round the armature so that there is no interference with the proper distribution of the magnetic fluxways. The pole faces, however, are spaced symmetrically round the armature, so that there is no interference with the proper distribution of the magnetic flux. The main field coils and the commutation coils are specially wound to such a shape as to fit into one another, so that practically no extra space is required for the additional coils, as is the case with some designs of commutation-pole motors. The general appearance of the motor will be seen from Fig. 3.

Ten motors of this type, for an output of 38 h.p., have been supplied by Messrs. Siemens Bros. Dynamo Works to the Hull Corporation Tramways, and a number of motors for 50 h.p. have been supplied, or are now under construction at their Stafford works for electric locomotives for the Harton Coal Co., in South Shields, for Brennan's experimental mono-rail car, and for the Adelaide Municipal Tramways Trust.

The following is a list of the stock sizes of these motors :—

Type No.	Voltage.	One hour rating.	Minimum gauge.
D 45 w a	500	25 h.p.	1 metre
D 53 w g	550	38 ,,	1 ,,
D 58 w a	550	50 ,,	1 ,,
D 71 w a	550	66 ,,	1 ,,
gD 120 w a	500	88 ,,	3′ 0″
gD 120 w b	750	75 ,,	3′ 0″
D 93 w a	800	75 ,,	4′ 8½″
D 93 w b	310	86 ,,	4′ 8½″
D 150 w	600	160 ,,	4′ 8½″
D 150 w	900	145 ,,	4′ 8½″

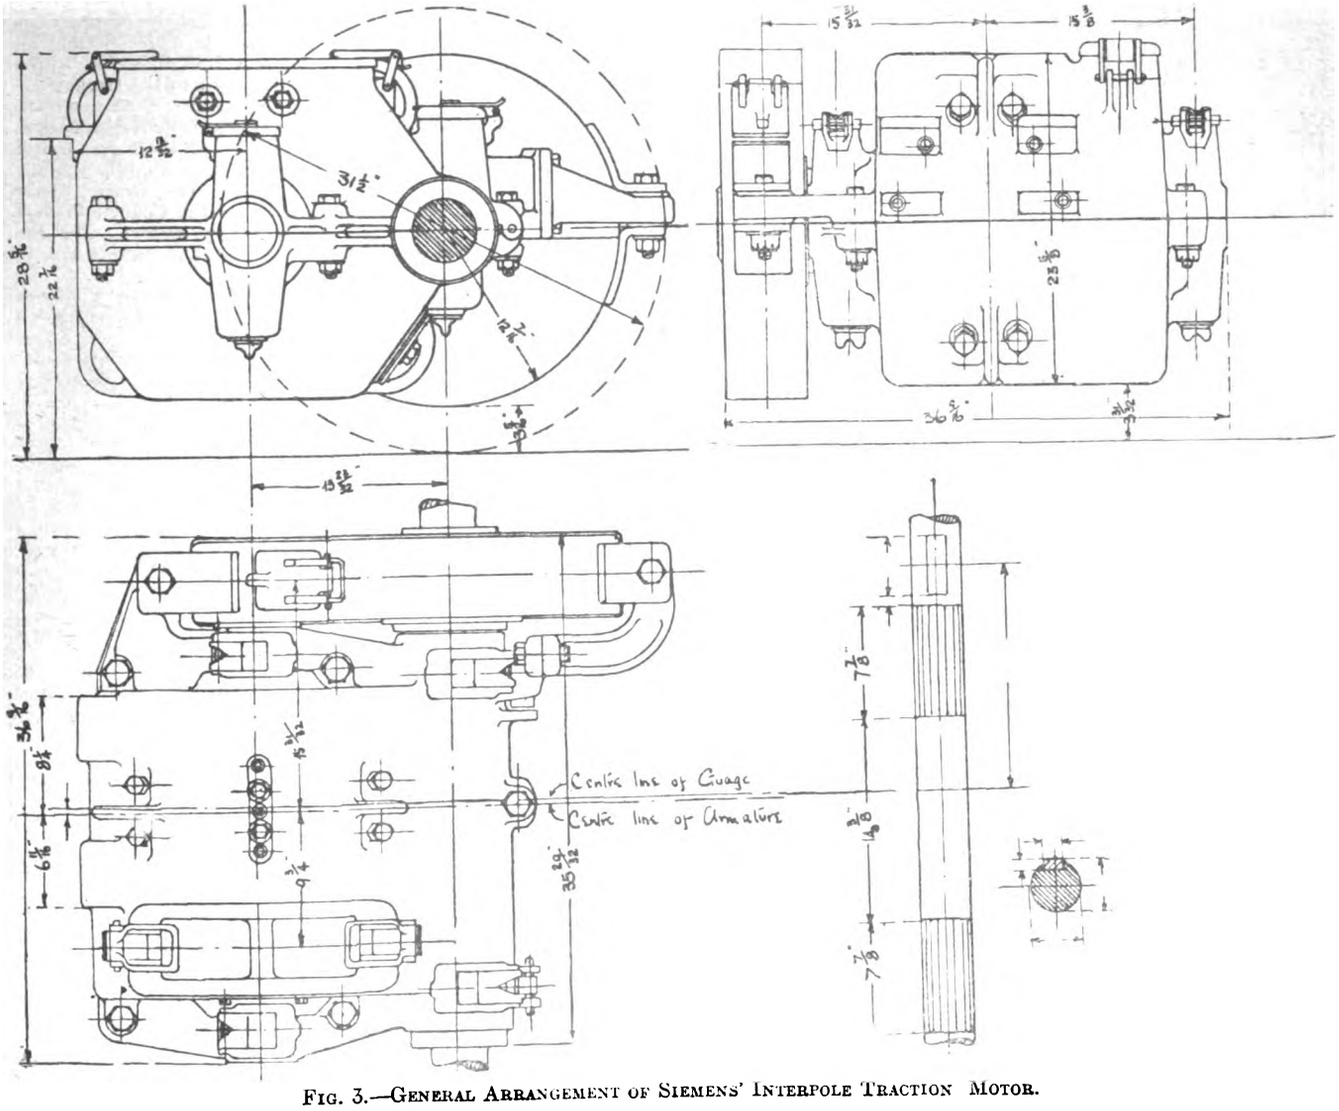

FIG. 3.—GENERAL ARRANGEMENT OF SIEMENS' INTERPOLE TRACTION MOTOR.

Messrs. Siemens Bros. Dynamo Works will be glad to work out for any particular case the saving of energy that may be expected by the use of their motors with the modified system of control.

LOCAL NOTES

AYR: *Tramway Accounts.*—The annual report gives the total revenue for the year as £15,081, as against £15,322 for the previous year. The traffic receipts were £14,444, which works out at 8·87d. per car-mile. The surplus on the year's working is £62.

ABERDEEN: *Electricity Accounts.*—The accounts of the Electricity Department for the year ended July 31st, 1909, record a total working expenditure of £19,622. made up as follows :—Generating, £10,294; distribution, £948; rents, taxes, &c., £5,720; management, &c., £1,683; miscellaneous, £977. The receipts amounted to £45.791, and of the balance £25,193 was absorbed by capital charges, &c., leaving a final £227, which has been carried to reserve. During the year 5,170,421 units have been sold, including 2,784,454 to private consumers, 291,848 for public lighting, 1,946,531 for Corporation traction, and 147,588 for suburban traction. The total figure for the previous year was 5,104,036. The capital expenditure now stands at £297,601.

BRADFORD: *Electricity Accounts.*—The total income from the last financial year has been £110,242, and the working expenses £52,131. Of the balance, after payment of capital charges, a net profit of £2,147 remains to be added to £3,223 brought forward from last year. Against this there had been charged £1,200, which had been allowed for rebate to tramways

Digitized by Google

for electricity supplied for traction purposes, also a transfer of £2,000 to revenue account with other sums amounting to £4,692, leaving an unappropriated profit at the end of the year of £678.

BUENOS AYRES: *Underground Electric Railway.—Reuter* states that the Chamber has adopted a Bill authorising the construction of an underground electric railway running across the city from east to west.

CANADA: *New Water-power Schemes.*—According to *Commercial Intelligence*, the British Columbia Electric Railway Co., and the Vancouver Railway Co., are preparing plans for the construction of a water-power plant on Vancouver Island for supply to Vancouver and Victoria. An American Consular report states that the Georgian Bay Power Company has increased its capital to $150,000 for the completion of a 3,000 horse-power hydro-electric plant, the light and power to be transmitted to that Canadian town.

CANTON: *Municipal Purchase of Electric Light Works.*—The electric light works is to be purchased from the China Electric Light & Power Co. for about £110,000 by the local authorities.

COLCHESTER: *Tramways.*—It is reported that the past year's working has resulted in a loss of £3,370 on the tramway undertaking

DUBLIN: *Speed of Dalkey Tramcars.*—Col. von Donop, of the Board of Trade, made an inspection of the route between the city boundary and Dalkey, upon which the Dublin United Tramways Co. seek to be allowed an increase of speed.

DUNDEE: *Claim against the Corporation.*—A large consumer lately connected to the mains has intimated a claim against the Corporation owing to the inability of the latter to supply current on February 1st, 1909, as per agreement. It will be remembered that the completion of the new station was delayed by the buildings, both of the station itself and sub-stations, not being completed as early as was originally intended.

The Fire at the Electricity Works.—It is reported that the damage done in the recent fire amounts to £1,589, exclusive of damage done to twenty-three transformers belonging to the British Thomson-Houston Co. Four old boilers and two generator sets damaged by the fire have been sold to Messrs. W. Kerr & Co., of Glasgow, for £550.

Museum Lighting.—Electric light is to be installed at the Dudhope Museum, and certain models, &c., are to be electrically driven.

EDINBURGH: *Electric Lighting Surplus.*—The Council have decided to devote the whole of the surplus on the electric lighting accounts, amounting to £2,182, towards the relief of rates.

Show-room.—The Electric Lighting Committee have under consideration the establishment of a show-room in connection with the electricity supply department for the exhibition of electrical apparatus for domestic and trade uses.

FRODINGHAM: *Street Lighting.*—A scheme for electric street lighting is under consideration which is estimated to cost £102 per annum, against £166 paid for oil lighting at present.

JOHANNESBURG: *Electricity Accounts.*—The profit on the electric supply department for the past financial year has been £52,000, and from the tramways £44,100. The cost of generation (according to the *Financial Times*) has been reduced from 1·07d. to 0·677d. per unit. It is stated that £67,000 is to be spent on power station improvements, and £60,000 on tramway extensions.

LONDON: *L.C.C. Tramways.*—The Board of Trade inspection of the lines from Nine Elms Lane to Queen's Road, Lavender Hill, took place on Tuesday, and traffic is to be commenced to-day. The further section to Clapham Junction is expected to be ready for inspection during the week.

Bermondsey: Reserve and Renewals Fund.—The Electricity Committee have had under consideration a letter from the L.C.C. as to the reserve and renewal funds in respect of wasting assets where loans had been advanced for 42 years. The committee point out that the Bermondsey Borough Council have recognised the need of a reserve fund, and there is one in existence at the present time with an amount to credit on March 31st last of £3,807, and after the current financial year it is intended to add to the fund until a limit is reached of 10 per cent. on the capital outlay.

Hammersmith: Tramways.—The Town Clerk has been instructed to make formal application on behalf of the Council to the Board of Trade to appoint a referee under Section 33 of the Tramways Act, 1870, to determine the difference with the London United Tramways, Ltd., in regard to the tracks.

PARIS: *Mishap on Metropolitan Railway.*—A short-circuit took place on Saturday on a train at the Caumartin station of the *Metropolitan*. Although no fire ensued there was considerable panic, and two passengers were injured slightly.

RAMSGATE: *The Tramway System.*—The Board of Trade has declined to accede to the request of the Council to inquire into the alleged defects of the tramway system. The Board has intimated, however, that it is prepared to receive a deputation on the matter.

SOUTH SHIELDS: *Salary of Borough Electrical Engineer.*—The South Shields Finance Committee have recommended the Council to reduce the salary of the Borough Electrical Engineer from £650 to £500, owing to the numerous complaints made by ratepayers regarding increased municipal expenditure at a time of general depression of trade in the district.

TASMANIA: *Water Power Scheme.*—A scheme is being promoted by Complex Ores, Ltd., to utilise water power from the Shannon and Ouse Rivers for electrically transmitted power.

VENTNOR: *Funicular Railway.*—An electrically-worked funicular railway is about to be constructed at a cost of £15,000 from the railway station to the esplanade and to the top of the Downs, to the plans of Mr. F. B. Behr. The cables will be driven by 40 h.p. and 30 h.p. motors respectively. The cars will have four compartments, will carry forty-six passengers each, and will weigh about 10 tons each loaded.

YARMOUTH: *Street Lighting.*—In response to an application for a loan of £2,000 for conversion of public lighting from gas to electricity in such streets as the Corporation may decide upon from time to time, the Board of Trade have intimated that it is not their practice to sanction loans for undefined expenditure on public lighting.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRIA.—*The Board of Trade Journal* announces that the communal authorities of Gloggnitz are arranging to erect electrical works, the power to drive which will be obtained from the Weissenbach waterfalls. It is proposed to contract a loan for the carrying out of the works in question, which it is estimated will cost 267,000 kronen (about £11,000).

It is also stated that the district authorities of Hohenfurt have arranged to construct as soon as possible an electric railway from Zartlesdorf to Lippnerschwebe. The cost of construction is estimated at 3,000,000 kronen (£125,000), to cover two-thirds of which it is proposed to issue a loan.

JOHANNESBURG.—It is stated that the municipality will shortly invite tenders for the following extensions to the plant at the power station:—Four boilers with mechanical stokers and economisers, one chimney and necessary flues, steam exhaust and circulating piping, cooling towers, cooling pond, feed-pumps, &c.

LONDON: *Stoke Newington.*—A distributor cable is to be laid in Green Lanes from Seven Sisters' Road to the Finsbury Park Hotel at an estimated cost of £84.

LOWESTOFT.—The Electric Lighting Committee have sanctioned the expenditure of £875 upon a new feeder.

SOUTH SHIELDS.—An inquiry was held on Friday into an application to the Local Government Board for a loan of £3,735, of which £2,600 is to be for duplication of mains, £135 for two additional traction panels on the switchboard, and £1,000 for services, connections, &c.

SPAIN.—According to *The Board of Trade Journal*, a provisional concession has been granted to Don Carlos E. Montañés for the construction and working of the Metropolitan Railway (Electric) at Valvidrera. It appears that the work will involve the boring of a tunnel. Two years are allowed for the completion of the work, excluding tunnel operations. Further information can be obtained at the Commercial Intelligence branch of the Board of Trade, 73 Basinghall Street.

It is also announced that Don José Curbera Fernandez has applied to the Dirección General de Obras Públicas, Madrid, for a concession for the construction and working of an electric tramway in the city of Vigo and suburbs, and that a period of one month from the date of the "Gaceta" is allowed for the presentation of competing offers at the above-mentioned Dirección.

Tenders are also invited for the construction and working of an electric tramway to run from Calle de Villanova to Calle de Wad-Ras, in Barcelona. Tenders, enclosed in sealed envelopes, and accompanied by a deposit of 3,193 pesetas (about £114), should be addressed to the above-mentioned Dirección, where they will be opened at noon on November 3rd. An application respecting this concession has already been submitted by the Sociedad Anonima Tranvías de Barcelona á San Andrés y Extensiones, who have certain preferential rights in the competition.

Miscellaneous

BILBAO.—According to a Consular Report, a large electric crane will be required in connection with a new dock at San Mamés.

CALCUTTA.—Mr. W. Shedden Paxton, manufacturers' agent (address, Post Office, Calcutta), requests us to state that he would be glad to receive price lists with full exports and cash discounts from makers of small motors and dynamos, 1/20 to 5 h.p.; also switchgear and regulators, &c., for use with same, and accumulators and lamps for motor cycles and cars.

COREA.—According to the *Board of Trade Journal*, 500 miles of new telephone lines are to be constructed at a cost of £7,150.

Digitized by Google

LOWESTOFT.—Mr. J. Chambers has applied for a supply of electricity for light and power to his shipbuilding yard, &c. In consequence of the pressure of supply on the station, another feeder is to be put in at an estimated cost of £875.

MONTEVIDEO.—The Commercial Tramway Co., of Montevideo, contemplate the installation of a further 1,500 kw. generating set.

NEWPORT (MON.).—The Borough Engineer has been authorised to expend £190 in renewing tramway rails, points, and crossings at various places on the tramway routes.

SOUTH AFRICA.—There is reason to believe that considerable extensions are shortly to be carried out in the Transvaal telephone system in the direction of linking up isolated existing systems and establishing main trunk lines to every point where the railway lines cross the border, for ultimate extension to the coastal ports and Buluwayo. The scheme contemplates connections with farmhouses and the establishment of call offices at convenient centres in rural districts. It is estimated that the coast extensions definitely undertaken will cost over £300,000.

VENEZUELA.—The *Board of Trade Journal* reports that permission has been granted to the Compañía Anónima Tranvías Eléctricos de Caracas to extend their system from Palo Grande to the Nuevo Matadero.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the ***whole building.***

LONDON.

E.C.—Cordwainers' Hall, Cannon Street. Architects, Chatfield, Clark & Son, Bishopsgate Street, E.C.

N.—School in Lordship Lane, Tottenham. W. H. Prescott, surveyor, Tottenham, U.D.C.

N.W.—Addition to sub-station at North Finchley, for the Metropolitan Electric Tramways, Ltd.

S.E.—Skating rink, Lewisham, S.E. Builders, Sheffield Bros., 1a Downs Park Road, Dalston, N.E.

Buildings on Nos. 258 to 262 Westminster Bridge Road (£7,500). Architects, Joseph & Smithem, 83 Queen Street, E.C.

Open-air wards at infirmary, Plumstead (£1,224). Architects, Church, Quick & Whincop, William Street, Woolwich, S.E. Builders, F. and G. Foster, Sunny Bank, Northwood Junction.

S.W.—Shops, &c., Tooting Broadway, S.W. Architect, C. Granville Baker, 5 Bloomsbury Square, W.C. Builder, F. W. Fletcher, Maybury Street, Tooting.

Extensive alterations to mansion, Halkin Street. Builders, W. Waring & White (1906), Ltd., 1A Cockspur Street, W.

PROVINCES.

ABERTILLERY (MON.).—School (£3,400). Builder, J. Morgan, Blaenavon.

AYLESBURY.—Stables, stores, sheds, &c. (£1,668). Engineer and surveyor, W. H. Taylor, Town Hall, Aylesbury. Builders, Webster & Cannon, Aylesbury.

BALLINGHAM.—Restoration, Parish Church. The Churchwardens.

BARGOED.—Twenty-eight houses. Architect, I. Leyshon, Hamburg Road, Bargoed.

DRIFFIELD.—Isolation Hospital. Surveyor to the U.D.C.

DUNDEE.—Skating rink, East Dock Street. W. S. Cruickshank & Co., Dundee.

DUNSTAN.—School (£5,000). Builder, Nordham, Dunstan-on-Tyne.

EAST HOWE.—School (£4,000). Architect, W. J. Fletcher, Shire Hall, Dorchester.

ECCLES.—Secondary technical school (£12,500). Architect, H. Littler, 16 Ribblesdale Place, Preston. Builders, W. Nicholson & Son (Leeds), Ltd., Hunslet, Leeds.

ELY.—Additions, infirmary (£4,000). Builder, J. Allen, Cardiff.

EPSOM.—Nurses' home (£1,450). Surveyor, J. T. White, Epsom Union.

GLOUCESTER.—Additions, Workhouse. The Guardians.

HEIGHTCLIFFE.—Residence (£1,000). Architects, Sharp & Waller, Brighouse.

HERTFORD.—Additions to infirmary. Clerk to the Guardians.

HEYWOOD.—Primitive Methodist School (£1,687). Architects, J. D. & S. J. Mould, Walmersley Road, Bury. Builder, F. W. Porter, Bury.

ILKESTON.—Elementary school (£7,290). Architect, H. Tatham Sudbury, Estate Offices, Ilkeston. Builder, A. Earnshaw, Ilkeston.

INVERGORDON.—Extensions to Academy (£2,500). Architect, J. J. McBeth, Queen's House, Inverness.

INVERNESS.—Skating rink (£2,000). Architects, Ross & Son, Queen's Gate, Inverness.

KEIGHLEY.—Skating rink. Architect, W. & A. Sugden, Keighley.

MAIDSTONE.—Hospital. Architects, Rock & Smith, 86 Week Street, Maidstone.

NEWBOTTLE.—School. Architect, T. Rushworth, Shire Hall, Durham.

NEWPORT (MON.).—Skating rink, for the South Wales Rink Co., c/o W. Longworth, 4 St. Mary's Parsonage, Manchester.

NUNEATON.—Skating rink. Architect, G. F. Ward, 71 Colmore Row, Birmingham.

PONTYWAM.—Extensions and alterations to county secondary school (£1,385). Architect, R. L. Roberts, Abercarn. Builder, J. Pritchard, Pontymister, Mon.

ROMFORD.—Art Gallery, Pyrgo Park, for Lord O'Hagan.

ST. ANNES.—School. Architect, H. Littler, 16 Ribblesdale Place, Preston.

STOCKPORT.—Extensions to infirmary. The Guardians, Stockport.

SUTTON.—Police station. Builders, F. Perks & Son, Mansfield.

TUNSTALL.—Pavilion (£1,200). Builder, F. Pemberton, Tunstall.

WANSTEAD.—Receiving homes (£21,000). Architects, J. T. Newman & Jacques, 2 Fen Court, E.C.

TENDERS RECEIVED AND ACCEPTED

BELFAST.—At the weekly meeting of the Tramways and Electrical Committee on the 20th inst., the offer of the Tudor Accumulator Co., London, for the supply of a milking booster was accepted.

CAPE TOWN.—Messrs. Pooley & Austin have received orders for the supply of a number of street-lamp fittings for the municipality.

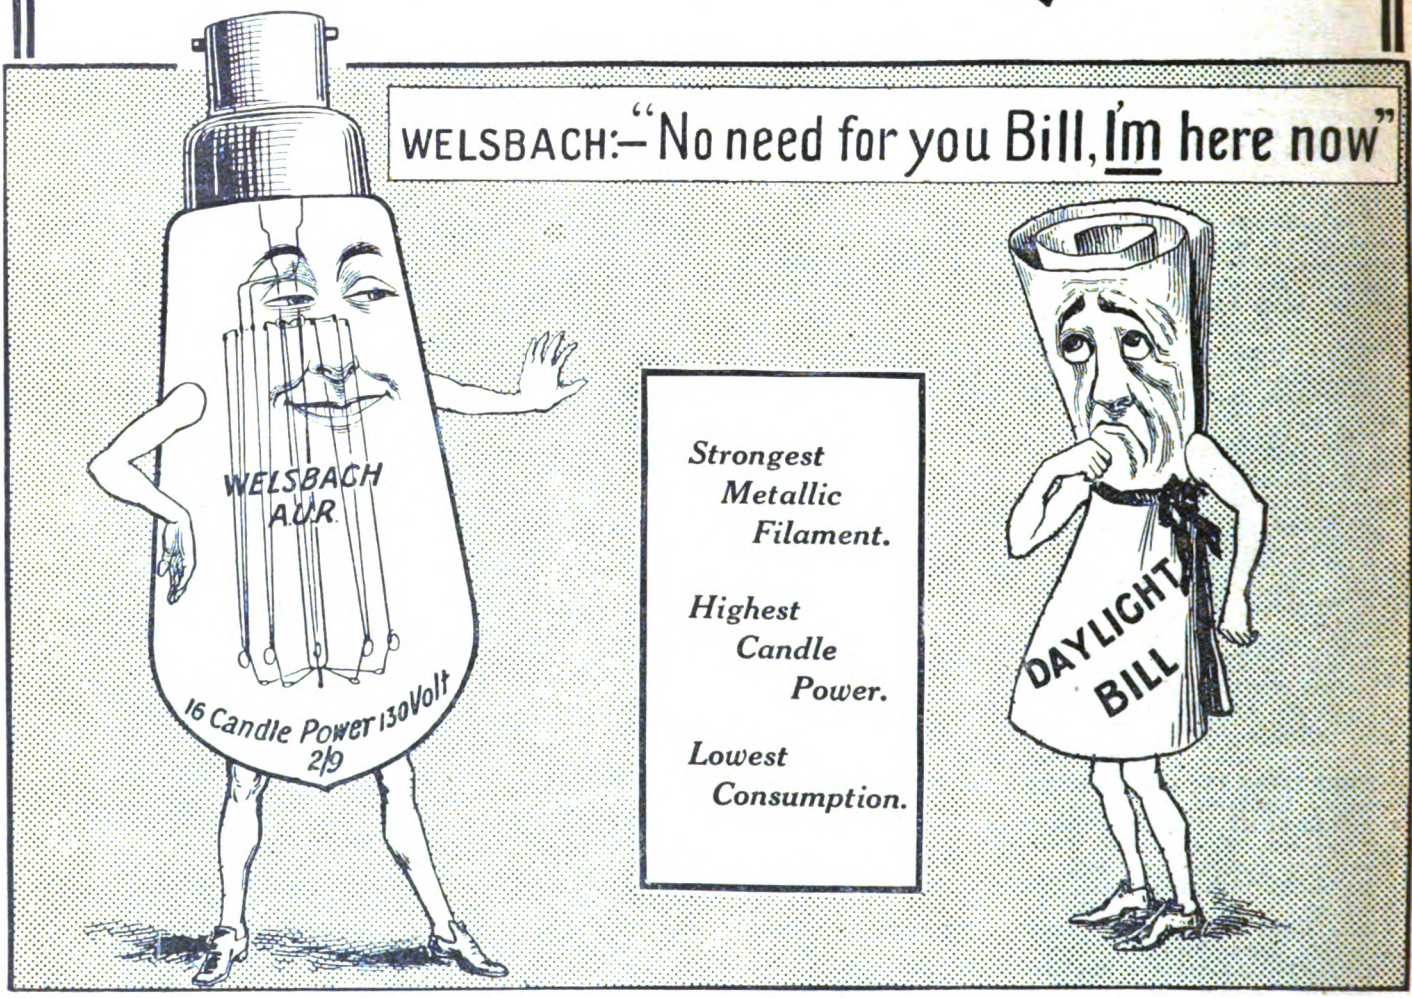
GENERAL POST OFFICE.—The following tenders have been accepted by the General Post Office: India-rubber and cotton core cable, W. T. Henley's Telegraph Works Co., Ltd., North Woolwich, E.; Johnson & Phillips, Victoria Works, Charlton, Kent; cable loops, British Insulated & Helsby Cables, Ltd., Prescot, Lancs.; Johnson & Phillips, Ltd., Victoria Works, Charlton, Kent; Western Electric Co., North Woolwich, E.; paper core cable, British Insulated & Helsby Cables, Ltd., Prescot, Lancs.; W. T. Henley's Telegraph Works Co., Ltd., North Woolwich, E.; Johnson & Phillips, Ltd., Victoria Works, Charlton, Kent; Western Electric Co., North Woolwich, E.; cupholders, galvanised steel, Bullers, Ltd., Tipton, Staffs.; insulators, Taylor, Tunnicliff & Co., Ltd., Eastwood, Hanley, Staffs.; tantalum lamps, Siemens Bros. Dynamo Works, Ltd. Tyssen Street, Dalston, N.E.; telephones, British L. M. Ericsson Manufacturing Co., Ltd., Beeston, Notts; British Insulated & Helsby Cables, Ltd., Liverpool; General Electric Co., Ltd., Peel Works, Salford; International Electric Co., Kilburn; transmitter telephone, Western Electric Co., North Woolwich, E.; electric lighting at Newton Street, sorting office, Manchester; J. Collier & Co., 29 King Street, West, Manchester; equipment at the Post Office, Central Telephone Exchange, Western Electric Co., North Woolwich, E.

GRIMSBY.—The tender of Messrs. Johnson & Phillips, of Charlton, for a two years' supply of cable at £757, has been accepted.

LONDON: *Fulham.*—The Council have just placed a contract with the Beeston Manufacturing Co., of Leeds, for 288 special lanterns and brackets in connection with improvements they are making on the Fulham Palace Road tramway route. These brackets are specially designed for placing on tramway poles, and the new arrangement will replace about 48 arc lamps and posts. The necessary switches for these lamps have been ordered from Messrs. the Reason Manufacturing Co., Brighton. Contracts have also been placed with the Stirling Boiler Co. for two of their patent water-tube boilers, having a capacity of 14,000 lbs. per hour each, and with the Underfeed Stoker Co., for two stokers and accessories, to work in connection with the new boilers.

Hammersmith.—A pump supplied on trial by Messrs. T. Parker & Co. (now the Rees-Turbo Pump Co.) is to be purchased for the sum of £102.

LOWESTOFT.—The Town Council has placed an order with the Shipley Fan Co., at £15 10s., for a fan for the generating station.



WAR OFFICE.—Tenders of Messrs. Siemens Brothers Dynamo Works, Ltd., for dynamos and for arc lamps have been accepted.

WEST HAM.—The Education Committee has received the following tenders for the installation of electric light at the Abbey School: The Alliance Electrical Co., Ltd., £383; W. R. Woodward, £362; Troup, Curtis & Co., £347; C. Larkins & Co., Ltd., £336; West Ham Corporation Electric Supply, £330; Whitehead Bros., £316; Pinching & Walton, £311; W. Simmons, £306; H. J. Whitehead, £304; E. P. Allan & Co., £297; Vulcan Electric Co., £286; Jackson Bros., £279; J. T. Halsey, £278; G. Weston & Sons, £264; Pemberton, Arber & Carey, £249; Rowland & Hulton (accepted), £236.

WINNIPEG.—Messrs. Jens Orten-Böving & Co., of London, have secured the order for the water turbines which the city of Winnipeg are about to install. The contract is to deliver five turbines of 5,300 h.p. and two of 450 h.p., the total value being $97,150.

Welsbach Electric Light

The Perfecting of the Metallic Filament Lamp.

☛ **Remember**—that the Electric Metallic Filament Lamp was invented by Baron Welsbach, and see that the trade mark "AUR" appears on every lamp.

The Welsbach Company's Special Offer.

To enable users to satisfy themselves, without any additional outlay, of the great superiority of Welsbach Filament Electric Lamps over other types on the market, as regards efficiency, strength and economy, we have pleasure in making the following offer:—

We will remove **the whole** of the CARBON Electric Lamps from any existing installation and will replace these with our standard Welsbach Filament Electric Lamps of at least equal candle power and will accept as settlement in full of our account the difference saved by the Consumer in his Electric Current Bill as ascertained by comparison with the corresponding quarter of last year.

This offer stands good for acceptance, and for free installation by us through our agents, anywhere in the United Kingdom up to and including the quarter ending Dec. 1909, so that the test shall terminate in the March quarter at latest.

WELSBACH ELECTRIC LIGHT SECTION,
Welsbach House, 344-354, Gray's Inn Road, King's Cross, London, W.C.

COMPANIES' MEETINGS AND REPORTS

UNITED ELECTRIC CAR CO.—The report for the year ended June 30th, 1909, states that after paying debenture interest amounting to £2,500, and charging £5,646 for depreciation, the profit for the year is £8,896, to which is added £6,187 brought from last year, making a total of £15,083. After deducting preference dividend for the six months ending December 31st, 1908, there is an available balance of £12,083. The directors recommend the payment of the preference dividend, less tax, for the half-year ending June 30th, 1909, and a dividend of 2½ per cent., less tax, on the ordinary shares for the year ending June 30th, 1909, carrying forward to next year £5,333. At the meeting on Sept. 15th Mr. G. Richardson, who presided, said that the output had been considerably below the capacity of their works and plant owing to slackness of trade. They were obtaining a fair share of the small number of orders being given out. Financially, however, the position was strong.

HALIFAX & BERMUDAS CABLE CO.—At the meeting last Friday it was announced that the available balance on the year's working is £3,312, as compared with £3,095 for the previous year. A dividend of 2½ per cent (equal to the interim dividend) is to be paid, with £812 carried forward. £817 has been spent in renewals at Bermuda. £9,600 debentures have been paid off during the year.

DIRECT WEST INDIA CABLE CO.—The annual report was submitted to the meeting last Friday. Out of an available balance of £5,189 (compared with £6,149 last year), a further 3 per cent. dividend is to be paid, and £3,387 carried forward. Repairs amounting to £3,820 were required last September, owing to the hurricane at Bermuda. Progress is being made with the company's wireless station in Jamaica. £7,400 debentures have been paid off.

DICK, KERR & CO.—The annual report records a profit of £28,168, of which, after payment of debenture and other charges, leaves £15,474 available, together with the £81,566 brought forward from last year. 6 per cent. dividends are recommended on the preference and ordinary stock, carrying forward £63,141. Severe competition is reported, and it is stated that the quantity of work carried out in all departments has been considerably below the average.

JOHNSON-LUNDELL ELECTRIC TRACTION CO.—The report for the thirteen months ended June 30th mentions the sale of the Southall works. The operations, it is stated, have been limited to carrying forward certain improvements in the apparatus and to maintaining the patents. Efforts to dispose of the patents have been unsuccessful. The meeting was purely formal.

UNDERGROUND ELECTRIC RAILWAYS COMPANY OF LONDON.—At the half-yearly meeting held on Tuesday, Sir Edgar Speyer, who presided, announced considerable progress in the affairs of the company. The temporary loan of £225,000 is to be paid off next month, on the redemption of the outstanding 4½ per cent. power-house debentures, and second debentures, by an issue of £1,000,000 4 per cent. power-house first debentures. The company would then be free of all floating debt. The net result of the half-year was a deficit of £16,240, which was a considerable improvement upon the deficit of £96,000 which had been estimated. The report shows an increase of traffic in all the tube railways as well as the District Railway, and a reduced working cost. The new premises at St. James's Park Station, to which the offices of the three tube railways have been moved, will result in a considerable saving. The report and accounts were adopted.

YORKSHIRE ELECTRIC POWER CO.—At the half-yearly meeting held in Leeds on Tuesday, the report abstracted on page 824 of our last issue was adopted. Mr. A. Lupton said that the increased output had been the result of new business, and more generating plant was required.

NEW COMPANIES

BOWERS & BARR.—Registered on August 23rd, with a capital of £2,000, to take over the business of electrical engineers carried on by F. C. Bowers and E. V. Barr, as "Bowers & Barr," at Great Yarmouth. Registered by Ferrier and Ferrier, 33 Hall Plain, Great Yarmouth.

ROBERT BOWRAN & CO.—Registered on August 19th, with a capital of £10,000 in £1 shares (3,000 preference), to take over the business of a general and electrical engineer and agent, iron and steel merchant, &c., carried on by R. Bowran, as "Robert Bowran & Co.," at 4 St. Nicholas Buildings, Newcastle-on-Tyne. Registered office, 4 St. Nicholas Buildings, Newcastle-on-Tyne.

ETNA LIGHTING & HEATING CO.—Registered on August 16th, with a capital of £1,000, to adopt agreements (1) with J. Warry and G. N. Arculus, and (2) with H. R. Prosser, for the acquisition of certain patents, rights, tools, blocks, and electros analogous thereto, and to carry on the business of electric and gas-fittings manufacturers, lighting and heating engineers and contractors, &c. Registered by C. Doubble, 14 Serjeants Inn, E.C.

PRESTWICH & BURT.—Registered on August 16th, with a capital of £1,500 in £1 shares, to acquire the interest of E. C. Lea in the business carried on by him at South Lane, Kingston-on-Thames, as Prestwich & Burt, and to carry on the business of manufacturing electricians, electrical and mechanical engineers and contractors, founders, dealers in electrical accessories, &c. Registered by William Hurd & Son, 25 Bucklersbury, E.C.

STERRY-SINGLETON CO.—Registered on August 16th, with a capital of £1,000, to adopt an agreement with F. W. Sterry and W. A. Singleton, and to carry on the business of financiers, promoters, concessionaires, agents, bankers, contractors, electrical and general engineers, dealers in oil sleepers and rails, manufacturers of and dealers in engines, accumulators, dynamos, motors, and rolling stock, &c. Registered by Kerr & Lanham, 16 Furnival Street, E.C.

SAMUEL MUCKLOW.—This company was registered on August 20th, with a capital of £5,000 in £1 shares, to take over the business of manufacturers of and dealers in bolts, nuts, rivets, screws, washers, railway, tramway, and telegraph fastenings, &c., carried on by S. Mucklow, at Hope Works, Old Hill, Staffs, rivet manufacturer. Registered by the Solicitors' Law Stationary Society, Ltd., 28-29 Chancery Lane, W.C.

NATIONAL LIGHTING CORPORATION.—Registered on August 30th, with a capital of £1,000, to carry on the business of electricians, manufacturers of and dealers in electric light, electrical appliances and novelties, &c. Registered office, 35 Cock Lane, Snow Hill, E.C.

UNIVERSAL TRANSMISSION SYNDICATE.—Registered on September 8th, with a capital of £71,000 in £1 shares (70,863 pref., and 60 "A" ord., and 77 "B" ord.), to adopt an agreement with the Universal Transmission, Ltd., F. H. Clergue, and W. L. Harrison, for the acquisition of the Williams-Janney-Waterbury Tool Patents, and applications for patents and rights in reference to certain inventions and improvements in power transmission devices, and other rights and premises therein mentioned, and to carry on the business of manufacturers and suppliers of and dealers in machinery, plant, engines, appliances, and apparatus, suppliers of motive or mechanical force, &c. Private company.

ELECTRICAL TROLLY HEAD CO.—Registered on September 8th, with a capital of £6,000 in £1 shares, to adopt an agreement with J. T. Cherry and E. H. Clive for the acquisition of certain patents, and to carry on the business of electrical engineers, manufacturers of and dealers in electrical trolly heads, &c.

DIOPTRIC SIGN CO., LTD.—Registered on September 6th, with a capital of £1,000 in £1 shares (250 cum. preferred, 500 ord., and 250 deferred), to acquire from E. L. Warren, the benefit of certain existing inventions relating to an improved sign, to develop and turn to account the same, and to carry on the business of electrical engineers, metal workers, shop fitters gas fitters, &c. Private company.

R. LASCELLES & CO.—Registered on September 4th, with a capital of £1,000 in £1 shares, to adopt an agreement with R. Lascelles, and to carry on the business of mechanical, electrical, and general engineers, manufacturers of and dealers in electric, magnetic, telephonic, and other apparatus, &c. The subscribers are T. Figg, A. F. Kemp, A. H. Kirkaldy, and R. Lascelles. Private company.

NATIONAL ELECTRIC SIGNS CO.—This company was registered in Edinburgh on September 8th, with a capital of £2,000 in £1 shares, to acquire the rights to erect and use in Great Britain the German invention, "Universal Licht-Reklame," and to carry on in the United Kingdom or elsewhere the business of general advertisers and contractors. Registered office, 112 Bath Street, Glasgow.

MISCELLANEOUS CITY NOTES

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO.—A dividend of 1 per cent. on the ordinary shares, payable Nov. 1st, has been declared.

SIR W. G. ARMSTRONG WHITWORTH & CO.—A 10 per cent. dividend has been declared on the ordinary shares.

UNITED RIVER PLATE TELEPHONE CO.—An issue of 30,000 ordinary shares of £5 each is announced to holders of ordinary shares on the register on 17th instant, in the proportion of one sew share for every four held.

FOLKESTONE ELECTRICITY SUPPLY CO.—An interim dividend of 4 per cent., payable Sept. 30th, has been declared.

HOVE ELECTRIC LIGHTING CO.—An interim dividend at the rate of 8 per cent. per annum, payable October 15th, has been declared.

NEW PUBLICATIONS

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 5s. to £60 15s. per ton (last week, £59 10s. to £60).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Official Receiver at Coventry has issued a summary of the statement of affairs in the bankruptcy of Herbert John Burdett, electrical engineer and contractor, of Rugby and Coventry. The liabilities amount to £1,213, of which £1,153 is expected to rank. The assets, after deducting preferential claims, are estimated to produce £334. Debtor gives as the causes of failure, "trade depression in Rugby, competition, bad debts, illness, and heavy rental." The first meeting of creditors was held on Monday. Mr. Alfred Cripwell, of Messsr. Corfield & Cripwell, Birmingham, was appointed trustee, with a committee of inspection.

WIRELESS CONTROL SYNDICATE.—At a meeting on Tuesday of last week, it was resolved to wind up the company voluntarily. Mr. E. Mason has been appointed liquidator. A meeting of creditors is to be held at 14 Gracechurch Street on September 30th at 4 p.m.

ELECTRICAL INSTALLATIONS, LTD.—We are informed that Mr. H. Bell has ceased to be secretary to this company, as from August 28th, and is no longer connected with same in any capacity whatever.

MESSRS. WRIGHT BROTHERS & CO.—The partnership between J. Hemmingway, C. Wright, and H. T. Wright, trading as Wright Brothers & Co., electrical engineers, 6 Queen's Elm Parade, Chelsea, has been dissolved. Debts by C. Wright and H. T. Wright.

Telegraph Traffic and Movements of Cable Ships.—News of telegraphic interruptions is sometimes a little belated, and we only now receive the information that the Government landlines in Cuba between Baracoa, Saguadetanamo, Moyari, and Preston were down late in August.—The Western Union Telegraph Co.'s cable has been damaged about midway between the Old and the New Worlds, and as the company has no repairing ship of its own, it is probable that either the *Mackay Bennett* or the *Minia*, which latter vessel is still on this side, will be chartered to repair the breaks.—On the 15th inst. the cable connection between Chicksaid and Perim of the Eastern Telegraph Co. was broken, and communication was interrupted between Tangier and Mogador. Telegrams for the latter place were despatched *via* Casablanca subject to delay.—The line between Bagdad and Bassorah was restored on Sept. 15th, but was down again on the following day.—On the 18th inst. the El Arich route was down between Gaza and El Arich.—Telegraphic communication beyond Catumbella, in Angola, was interrupted on the same day, telegrams being subject to delay.—The El Arich route was restored on the 19th inst.—On the 20th inst. it was once more possible to send telegrams between Tangier and Mogador, but the Bagdad-Bassorah line ceased operating. The French Cable Co. succeeded in mending their cable between Puerto Plata and Martinique on the 17th inst., thus once more connecting up South America with their cable system.

After the *Colonia* completed the laying of the New York-St. John's (Newfoundland) cable of the Commercial Cable Co. in August, and landed some surplus cable at Halifax, N.S., she proceeded to recover the abandoned portion of the diverted cable between Causo and Flemish Cap.—The cs. *Mackay Bennett* was engaged in a repair of one of the company's cables, and also lifted a part of the shore end from the point where the *Colonia* cut in, some distance from Causo. She then left for St. John's, Newfoundland, where she laid the picked-up cable in the harbour. The diversion of the southern section, it is understood, will be proceeded with in the near future.—The French Company's cable steamer *Contre Amiral Caubet* was engaged in a repair on the St. Pierre-Cape Cod section some 170 miles from Halifax, N.S., where she cut out a fault of long standing, necessitating the expenditure of about 10-12 nautical miles of cable.—The cable ship *Minia*, belonging to the Anglo-American Cable Co., is still in English waters.—The Western Union Telegraph Co.'s cables have received attention at the hands of the cable ship *Mexican* between New York and Causo, a fortnight being occupied in this work. The ship arrived in New York on the 31st ult.

At the Congress of Empire Chambers of Commerce, now being held in Sydney, Sir Albert Spicer moved a resolution put forward conjointly by the London, Sydney, and Montreal Chambers, that "This Congress is of opinion that it is desirable to complete the Imperial route between the Motherland, Canada, Australia, and New Zealand by State-owner electric communication across Canada to Great Britain, and that the postal departments of the various Governments of the Empire should be requested to frame a combined scheme of substantial reductions in telegraphic rates." After the addition of the words, "Especially in the direction of cheapening Press cablegrams," the resolution was adopted.

CORRESPONDENCE TUITION FOR ENGINEERING STUDENTS

ON Saturday last the proprietors of the International Correspondence Schools entertained some 450 of their students at their headquarters in Kingsway, London, and afterwards at a dinner at the Hotel Cecil. Special visits to Richmond and Hampton Court had been arranged for Sunday also. The work of the schools, which were founded in 1891, is controlled by two affiliated organisations. One, with headquarters in London, deals with the work of the students in the United Kingdom and the British Colonies, and the other, with headquarters in New York, with that of American students. The total capital of these organisations is stated to be as much as six million pounds, of which sum £2,400,000 is in active use. About 3,000 students are actual shareholders, and the institution is rapidly developing into a co-operative organisation for technical education. There are branches and agencies in practically every country. In Great Britain alone there are 50 branch offices, and we are informed that the students in the British Empire number over 100,000. The average age of the students is between 26 and 27 years.

The dinner on Saturday was presided over by Sir Thos. Brooke-Hitching, a Member of the Commercial Education Committee, London Chamber of Commerce, in the absence of Lord Montagu of Beaulieu. The company included in addition to the speakers mentioned below, Mr. A. S. Ackerman, Sec. Society of Engineers; Mr. J. Adamson, Hon. Sec. Institute of Marine Engineers; Sir Edward Fithian, Sec. Association of Chambers of Commerce; Prof. Dr. Raithel, of Metz University; Mr. A. D. Field, Manager of the Western Electric Co., and many others.

In proposing the toast of the "International Correspondence Schools," the chairman spoke highly of the work of the institution, and of its methods, and referred to the great importance of technical education and of individual effort to maintain the position of Britain as a manufacturing and industrial country as near the front as possible. Replying to this toast, Mr. E. A. Seitz, the managing director of the Schools, mentioned the care and expense which had been gone to to gather together the best information in each branch of instruction, and said that some £15,000 had been spent in the preparation of the text-books for the Electrical Engineering Course alone. The schools were not in competition with evening technical classes, and a large number of their students were works managers and foremen who naturally did not care to sit with apprentices and boys in evening classes. There were over 350 representatives of the schools carrying on an active propaganda in the provinces, enrolling, encouraging, and assisting students, and placing them in touch with employers. In proposing the toast of "Education for the Wage Earner," the chairman referred to the chances now offered to the poorest student to rise to the Universities, and spoke of the necessity of application and perseverance to all who desired to go ahead. In replying to this toast, Mr. Dennis Hird, Central Labour College, Oxford, congratulated Mr. Seitz on the success of the schools, and enlarged on the nobility of education. The toast of "I.C.S. Students at Home and Abroad" was proposed by Mr. L. A. Atherley-Jones, K.C., who said that although oral instruction was in some ways superior to written instruction, the instruction given did not in most cases come up to the standard offered by these schools as regards clearness and practical utility. The student could select, also, exactly what instruction he wanted, and enjoy it at any time he desired. He concluded by reading some telegrams conveying greetings from students in Australia, South Africa, and India. Mr. W. G. Wilson, the secretary of the Eccles Spinning & Manufacturing Co., and an old student of the schools responded, and gave some further details of the system, pointing out that £50,000 was spent annually in revising the courses and keeping them up to date. The toast of the guests was proposed by Mr. D. F. Odell, and responded to by Col. S. S. Long, Assistant Director of Supplies, Woolwich Arsenal, on behalf of the I.C.S. Army students, many of whom were present. Mr. J. M. Macdonald and Mr. J. T. Macpherson, M.P., also responded to this toast.

Electric Light and Power in Sicily.—According to a British Consular report, the Società Elettrica della Sicilia Orientale, which obtained from the Italian Government the concession of the Cassibile River, with the object of utilising the water for electric power, has made rapid progress with the construction of the works. The average quantity of water to be utilised is 220 gallons per second, which, with a fall of 230 ft., will produce 3,000 horse-power. The Vice-Consul in Messina reports that during the year 1908 a large generating station was erected in Messina, and the process of the installation of electric light in houses and shops had commenced. Owing to an unexpired contract between the Messina Town Council and the gas company, the lighting of the streets by electricity could not be undertaken except along the quay. An agreement had also been come to for the conversion to electric traction of the steam tramways which ran through Messina and along the coast to the south and north of that city. The works and the distributing system have been almost completely destroyed by the earthquake, however.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A SERIOUS magnetic storm disturbed telegraph traffic last Saturday. (Page 850.)

QUESTIONS asked in the House of Commons have elicited the information that the Home Office regard enclosed motors, and not merely flame-proof motors, essential in gassy mines, and that no sum has been allocated by the Government to experiments with electrical plant in mines.—We publish further letters as to directions in which improvement could be made in present-day methods regarding electrical work in collieries (Page 851.)

The new design of the Jandus enclosed flame arc lamp and a combined wall plug and adaptor are described on page 852.

A NUMBER of designs of vertical shaft motors, both for three-phase and continuous-current, have been developed by the Felten & Guilleaume-Lahmeyerwerke for special purposes, such as the driving of sinking pumps in mines. (Page 853.)

TRIAL runs are being made with a trolley omnibus on an experimental road at Hendon. The car has two 25-h.p. motors driving countershafts through bevel gears. A two-wire overhead construction is used, and, contrary to Continental practice, the frame of the car is electrically connected to the earthed negative trolley wire. A device to warn the driver if the car becomes connected with the positive wire is provided. As an alternative a three-wire line may be employed. The two sets of trolley wheels are mounted on the same head at the end of a double pole, and means are provided to counteract the side pressure when the car deviates from the centre of the road. (Page 855.)

IT is proposed to deposit a Bill in Parliament next session for powers to construct a tube railway from Victoria to the Crystal Palace. Mr. Stephen Sellon is advising the promoters. (Page 858.)

IN the House of Commons last week the Postmaster-General said that the action of the Government in proposing to purchase the land stations of Marconi's Wireless Telegraph Co. would in no way prohibit free competition between various systems. A French com-

Digitized by Google

pany is to erect a wireless telegraph station on the Island of Fernando Noronha, with a range of 1,000 miles. (Page 858.)

AMONG the specifications published by the Patent Office on Thursday last was one by J. Spiliotopol for a primary cell, in which both negative electrode and depolariser are restored to the condition before discharge by heating the cell. A method of fixing connecting sockets to silundum rods used as heating or resistance units, by casting metal round the ends and cooling under pressure, or by pressing on metal sleeves at a red heat, is protected by G. Cooper and F. C. Sharp. Messrs. Siemens Bros. Dynamo Works, Ltd., have a specification describing a new design of portable electric drill, in which the casing is divided in a plane passing through the axes of motor shaft, counter shaft, and drill spindle. Additional safety precautions in connection with the balanced transformer system of mains protection are covered by the Allgemeine Elektricitäts Ges., and the Westinghouse Electric Co. protect a design of track brake in which the shoes are carried on travelling supports not rigidly connected to the locomotive or car frame. Leave is sought to restrict the scope of a patent by H. S. Martin for an adjustable carbon powder resistance. The grant of a patent to H. Hunte for a dry cell with vertical air passages through the depolariser, is opposed. (Page 859.)

A PROPOSAL that negotiations be re-opened for the sale of the Acton electricity undertaking to the Metropolitan Electric Supply Co. was not carried at a recent meeting of the Acton Council.—A scheme for constructing a central tramway depôt in Bradford for accommodating 150 cars is under consideration.—Through running between the Croydon and L.C.C. tramway systems has considerably increased the receipts on the former lines.—Mr. J. F. C. Snell is to report upon the Gillingham electricity undertaking at a fee of 150 guineas.—A net profit of £415 is shown by the accounts of the Hanley electricity undertaking for the year to March 31st.—Leeds Corporation propose to apply for powers to adopt the railless electric traction system. (Page 860.)

GLASGOW Corporation require main switchboard, cables, switches, &c., and the Walthamstow Council cables. Applications for loans are proposed as follows:—Southend, £13,715; Leicester, £7,000; Southampton, £3,000. (Page 861.)

THE accounts of Messrs. Willans & Robinson for the June half-year show a loss of £3,501. At the annual meeting of Messrs. Dick, Kerr & Co., on Tuesday, it was stated that the past year has been the worst for many years, and that the directors can hold out no hope of an immediate improvement. (Page 863.)

THE annual conference of the Municipal Tramways Association was held in London last week. In his address, the President, Mr. A. L. C. Fell, dealt with the present status of tramway undertakings, and indicated some of the directions in which future developments might be expected. A Paper by Councillor A. W. Chapman, on the medical examination of tramway employees, produced a spirited discussion, most of the speakers being in favour of examination, both initially and at frequent intervals. Mr. W. E. Ireland read a Paper describing the equipment of the L.C.C. repair shops at East Greenwich, and incidentally gave some interesting figures relating to the life of steel tyres, pinions, brake-shoes, &c. A Paper comparing Continental and British tramway practice, by Mr. A. R. Fearnley, aroused some discussion on the relative merits of single- and double-deck cars. The results of training drivers and installing meters on cars with a view to reducing the current consumption on the Aberdeen system were given in a Paper by Mr. R. S. Pilcher. (Page 864.)

THE MAGNETIC STORM

ACCORDING to official information, the first effects of a very serious magnetic storm on Saturday were felt at about noon, when telegraphic communication throughout the country was interrupted. Until late in the evening the working was intermittent. This, however, applies only to the overhead systems, as the underground lines were always practically free from the effects of the disturbance. The storm appears to have made itself felt more or less throughout the world, and the submarine cables were also affected to some extent. The last serious storm of a similar magnitude occurred on October 31st, 1903, and it is a noteworthy fact that the views as to the origin of magnetic storms do not appear to have undergone much change in the interval. These magnetic storms generally follow the appearance of a sun-spot, and it is thought that the eruption causing the sun-spot results in the emission of a stream of electrons which, if it encounters the earth's atmosphere, is deflected to the poles, and produces currents in the earth's crust. A large spot had been in evidence on the surface of the sun for several hours before the disturbance of Saturday. Dr. Chree stated to a *Times* correspondent that the records at Kew Observatory showed that the disturbance began at 11.22 a.m. on Saturday, and that the magnetic conditions of the earth remained highly disturbed until 8.30 p.m.; the disturbance had almost disappeared at one a.m. on Sunday morning.

High Voltage 22½ c.p. Osram Lamp.—The General Electric Co., Ltd., announce that on and after to-morrow they will be able to supply 32 watt Osram lamps for working on 200 to 260 volt circuits. The candle-power will be 22½ British c.p. (25 Hefner c.p.), and the lamp will burn at any angle.

Telegraph Traffic and Movements of Cable Ships.—The magnetic storm which was the cause of considerable disturbances on submarine and land lines on Saturday last is referred to above. The Argentine Chamber has passed the Bill, which already had the approval of the Senate, authorising the Western Telegraph Company to lay a direct cable from the Republic to Ascension.—The cable between Tangier and Cadiz was restored to working order on the 21st inst.—On the 23rd inst. telegraphic communication with Bailundo was restored, although interruption of the wires to Quimbale still continued. On the 26th inst. the cable between Tangier and Mogador was again in working order, but it appears from recent events that the various lines to Morocco are likely to be disturbed again at any moment.—On the 25th inst. the French Cable Company succeeded in putting their section between Mole St. Nicholas and Cape Haiti into working order again.—On Monday last trouble again occurred on the Bagdad-Sassorah line.—The Australian Government has decided to introduce the Wheatstone telegraph system in New South Wales, Queensland, South and Western Australia.—The announcement that the Postal Company had absorbed the Western Union Telegraph Co. has been officially denied, and so competition across the Atlantic will continue.—This month the new cable repairing steamer of the Western Union Telegraph Company was launched at Tottenville, Staten Island. The vessel was christened the *Robert C. Clowry*. She is 150 ft. long, and 32 ft. broad, and will be ready for service about December 1st next.

Civil and Mechanical Engineers' Society.—The opening meeting of the session of this Society will be held at Caxton Hall, Westminster, on Thursday, October 7th, at 8 p.m., when Mr. W. N. Twelvetrees will deliver his Presidential Address.

Tramcar Speed Indicators.—In the House of Commons last week, Mr. Joynson Hicks asked whether the Home Office would consider the question of compelling tramway authorities to fix on their cars a device for making a continuous noise when the speed exceeds a certain limit, as was now done in the case of motor omnibuses. Mr. Masterman replied that the question was under consideration, but the application of the device to tramcars presented special difficulties, owing to the varying limits of speeds authorised for tramways. Mr. Myer asked if Mr. Masterman was aware that some of the cars on the Thames Embankment travelled at a speed of over 20 miles per hour, but no answer was given.

Tramway Provisional Orders, 1909.—The number of applications made to the Board of Trade in December, 1908, for Provisional Orders under the Tramways Act, 1870, was five, viz.:—Bolton Corporation, Keighley Corporation, Morecambe Corporation, Portsmouth Corporation, Whitworth Urban District Council. All the applications were for powers to construct new or extension tramways, and all were promoted by local authorities. The aggregate length of the proposed tramways was 4 miles 74 chains of double line, and 6 miles 50 chains of single line, and the estimated cost was £121,317. Provisional Orders were granted in every case, and a Bill to confirm the Orders was introduced into the House of Lords on May 3rd. This received the Royal Assent on September 20th, 1909.

ELECTRICAL INSTALLATIONS IN MINES

DURING the interval before the definite establishment of the Committee which is to report on the Special Rules for the use of electricity in mines with a view to their amendment, the attention of the House of Commons is still being directed to the subject. The Home Secretary has decided on the much-discussed question as to whether total enclosure or flame-proof cases are called for in the case of motors working in gassy mines (in which General Rule 8 applies), and has given the ruling that total enclosure is necessary, and that a flame-proof motor will not comply with Special Rule 37. This rule has, however, been noted for reference to the new Committee.

Questions were also asked as to whether the Government were going to institute experiments in connection with the use of electricity in mines.

In replies on behalf of the Chancellor of the Exchequer and the Home Secretary, it was stated that no such application for funds had been made, nor had any recommendation been received from the inspectors of mines as to the necessity or urgency of any experiments with regard to electricity. The Home Secretary had, however, seen a Paper read at the Institution of Mining Engineers by Mr. R. Nelson, H.M. Electrical Inspector of Mines, in which he suggested that certain experiments on live cables would be of interest, and might be valuable. The whole subject of the regulations for the use of electricity in mines was about to be referred to an expert committee, who would doubtless consider how far any such experiments would be useful, and by whom they could best be made. Their recommendations would have the Secretary of State's most careful consideration.

We have received the following correspondence on this subject. Previous letters will be found in our issues of Sept. 9th, 16th, and 23rd, and further correspondence is invited from men having practical experience in the erection and working of electrical installations in mines:—

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—Referring to your article on "Electrical Installations in Coal Mines" in your issue of the 2nd inst., it is an interesting fact that the vast majority of the recent electrical fatalities in mines have been in connection with alternating currents, and this in spite of the preponderance of direct-current installations in coal mines. It is well known that a shock from an A.C. source is more severe than one from D.C.; the muscles of the body contract with an alternating-current shock, and the victim is gripped and unable to release himself. With a D.C. shock the victim is usually thrown clear at the moment of contact in a probably unpleasant fashion, but one that is less offensive than that of the alternator. The usual supply voltage in mines is about 500, both for alternating- and direct-current installations.

Under the Coal Mines Regulation Act the mine has to be inspected daily by experienced officials to ensure that everything is right (from a mining point of view) before the men enter. Every winding rope has to undergo a similar inspection, but yet I have seen pit cables with their insulation damaged and hanging in rags, and in such a condition as to be a death-trap for the unwary passer-by, and a likely source of fire. Too much reliance is often placed on the leakage current indicator, which will not necessarily show up an abraded (unarmoured) cable; and armoured cables, being more liable to fire and having been the cause of several fatalities, are looked upon with suspicion in many quarters.

The use of an additional core or cable connecting all motor frames, switches, fuses, joint boxes, &c., to the bedplate of the generator, and suitably earthed, is perhaps a step in the right direction; but even this does not meet the case. The only safe method is constant examination of the cables inch by inch in conjunction with the regular use of proper testing instruments.

Manufacturers of electrical apparatus may do all in their power to make it efficient, but of what avail if it is not properly looked after and kept in decent repair at the colliery.

Wakefield, WM. A. LOGAN.
September 20th, 1909.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—The article in your September 2nd issue and the correspondence in the following issues indicate the necessity of an immediate revision of the special rules for the use of electricity in mining. Recent accidents have been the result of faulty earth connections, and this points to the need there is for frequently testing the earth connections of all metallic coverings, armouring, and frames, and the same precautions to be taken in earthing all low-pressure appliances.

I am strongly in favour of using bitumen-insulated wire armoured cables for shaft and underground work; the armouring can be efficiently bonded at junction boxes, and a good earth connection made from the surface, and all motors, switches, and frames earthed to the cable armouring. To make it more reliable, an additional earth connection can be made in the sump at the pit bottom. To earth these appliances where unarmoured cable is used is often a very difficult matter.

Another source of danger and frequent cause of trouble is the type of switchgear which is in use at some mines. This part of the mining installation requires careful consideration, and there is no doubt a considerable amount of weeding out to be done before this part of the equipment is rendered safe. Sealing-in points, easy access for inspection, coupling up and adjustment, also a larger carrying capacity to meet the abnormal demands made in mining work, are weak points which need attention. Section I., Rule 11 of the Special Rules is not very definite. No matter how competent a person is, if he is not invested with the authority which the position demands, he cannot be held as responsible as if he had the entire control of the installation and the men who have to handle the electrical appliances. Probably the committee appointed to revise the rules will give the man in charge a more definite position.

It would no doubt be an advantage to the committee if they had placed before them some of the practical experience which has been given in these columns. The alarmist views taken by the miners in the Durham district will no doubt do good, but there is every reason to believe that confidence will soon be restored. The revised rules and the experience and increased efficiency of those engaged in this work will do much to reduce these dangers to a minimum.

East Kirkby, Notts. Yours faithfully,
September 27th, 1909. F. CUSWORTH.

Nuisance from L.C.C. Sub-station.—In the House of Commons last week Sir William Collins called attention to the noise made by the machinery at the L.C.C. tramway sub-station at Arlington Road, Camden Town. Mr. Winston Churchill replied that the London County Council informed him that they were making experiments with a view to eliminating the noise complained of, and that there was every prospect that it would be reduced at an early date.

The L.C.C. Tramways at Woolwich.—It is stated that the Astronomer Royal, who has the power of veto with regard to the electrification of tramways within three miles of Greenwich Observatory, has withheld his consent to the equipment of the portion of line from Beresford Square to the Free Ferry on the ordinary overhead system, for fear of disturbance to instruments at the Observatory. The contract had already been placed with Messrs. Dick, Kerr & Co., and a commencement of work had been made. In view, however, of the position taken up by the Astronomer Royal all operations have been suspended. The same difficulty has arisen in connection with the line from Woolwich to Eltham, which is still awaiting the sanction of the Astronomer Royal. According to the *Times* it is likely that a solution of the difficulty will be found in the adoption of a form of three-wire system. In the meantime the conversion of the section from Rainton Road, Greenwich, to the "Lord Howick," near Woolwich Dockyard, to the conduit system with double track, involving an expenditure of £10,950 on street widening, is to be taken in hand at once. There will still remain about a mile of horse tramway from the Dockyard to the Free Ferry, and this will entail a heavy further expenditure on widenings, including the setting back of the Dockyard wall before it can be converted.

A New Metal Filament Lamp Manufacturer.—The "Thorium" Metal Filament Lamp Works, Ltd., has been formed with a capital of £30,000 for the purpose of taking over the Britannia Lamp Works in South Tottenham, and manufacturing metal filament lamps. A report concerning the works has been made by Mr. A. C. Hyde, which states that the plant at the works is sufficient to deal with an output of 300,000 lamps a year, and that the pumping plant is arranged in an exceptionally good way. As regards the lamp itself, Mr. W. J. Hide, of Liverpool, in a report to the underwriters, mentions that the particularly noteworthy feature in it is the arrangement of the bottom supports. The filament is rounded through the support instead of being drawn up sharply, and forming an acute V. The latter arrangement, he says, has led to frequent breakages, as in his opinion such breakages take place when the filament is cooling after the lamp has been switched off, owing to the filaments having been strung too sharply on their supports, so that there is no room for contraction. By the arrangement of the bottom supports this is said to be obviated in the "Thorium" lamp.

THE JANDUS ENCLOSED FLAME ARC LAMP

THE accompanying drawing represents the latest form of the enclosed flame arc lamp manufactured by the Jandus Arc Lamp & Electric Co., Ltd. (Hartham Works, Holloway), and put on the market by them under the name of the Jandus regenerative lamp. The lamp shown embodies all the improvements described in the article in ELECTRICAL ENGINEERING, September 16th, 1909, page 824. The rocking lever, to which are attached the clutch lever and the plungers of the controlling magnets, is mounted on phosphor bronze ball bearings, which

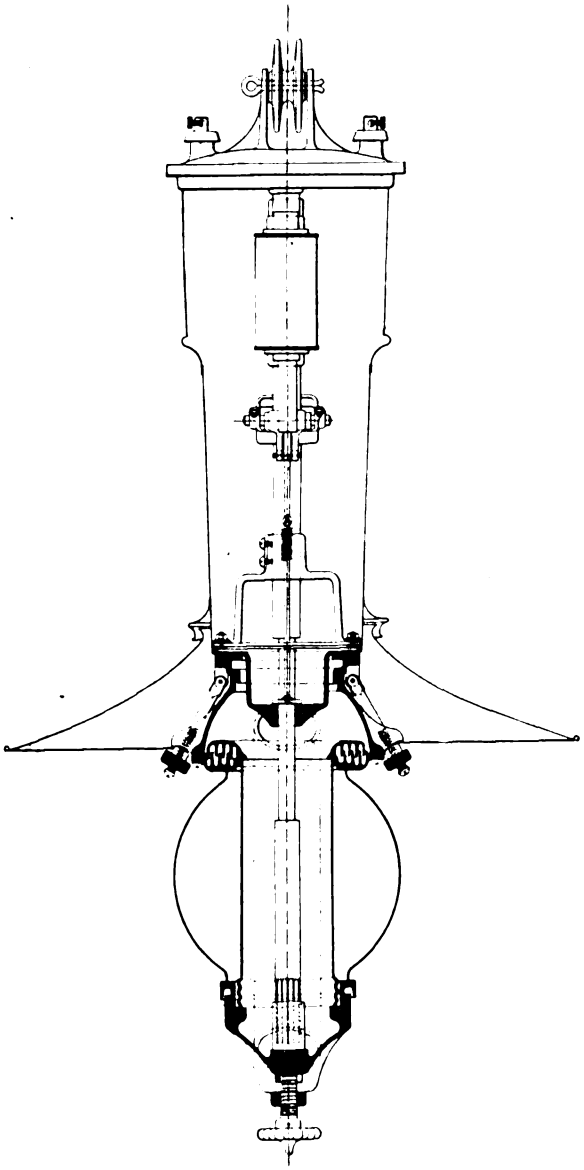

FIG. 1.—IMPROVED PATTERN OF THE JANDUS ENCLOSED FLAME ARC LAMP.

ensures greater steadiness of the very sensitive flame arc. The new pattern of lower holder, comprising a short piece of brass tubing split across two diameters, can be seen in the illustration, as well as a new arrangement of locking levers, which has been designed to facilitate the removal of the metal depositing tubes and ventilating caps for cleaning. The latter, which are furnished with annular baffling ridges, are now constructed of aluminium.

As mentioned in the recent article referred to, the design of the carbons has been altered considerably, the upper carbon now having six soft cores spaced symmetrically about the centre so that it shall burn to a point. The cores are composed of a mixture of carbon and a special chemical paste, giving a fat arc. As in the original pattern, the lower carbon is star-shaped in section, the grooves being filled with a paste. We are informed that the new carbons give a mean hemi-spherical candle-power of 3,000, and cost less than 0·1d. per hour.

Fig. 2. shows the candle-power curve of a lamp consuming 460 watts, and giving a mean hemispherical candle-power of 5,160, with an efficiency of 0·166 watts per candle. The maximum candle-power is over 4,000, at an angle of 15 degrees below the horizontal, which is most suitable for street lighting. The lamp can be burnt either on direct or alternative current

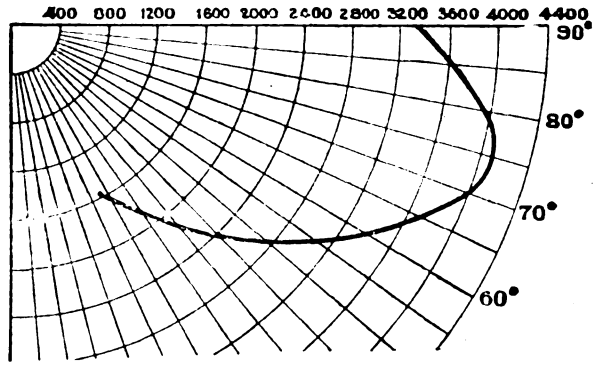

FIG. 2.—DISTRIBUTION OF CANDLE-POWER OF JANDUS ENCLOSED FLAME ARC LAMP.

circuits, and takes 8 amps., burning two in series on 110 volts, or four in series on 220.

COMBINED WALL PLUG AND ADAPTOR

MESSRS. E. H. JONES & MEAKIN, LTD. (27 and 28 Birkbeck Bank Chambers, Holborn, W.C.), have sent us a sample of an ingenious wall plug, which can be used equally well as an adaptor to fit an ordinary lamp-holder. The construction is very clearly shown in the two figures below. When used to put into a lamp-holder, the projecting plunger is left as in Fig. 1; the two pins fit into the bayonet slots of the lamp-holder, and the two brass plates at the top make

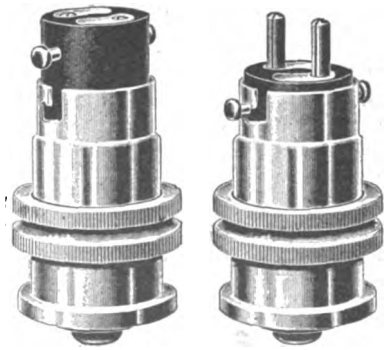

FIG. 1.—TO FIT LAMP-HOLDER. FIG. 2.—TO FIT WALL SOCKET.

contact with the lamp-holder plungers in the ordinary way. When used as a plug, the black plunger is pushed down as shown in Fig. 2, and the two spring pins are left projecting. The gauge of these pins is that of the ordinary midget type wall plug. This combined wall and lamp plug will be extremely useful in domestic installations and offices, especially for apparatus such as fans and portable lamps, which, with its assistance, may be connected either to a wall socket or any lamp-holder.

Brussels Exhibition, 1910.—The chairman of the committee of the National Electrical Manufacturers' Association has just returned from Brussels, and once again draws attention to the importance of this exhibition, which commences in April next year. On page 712 of our issue for August 5th last, we published a letter from the secretary of the Association, in which attention was drawn to some of the directions in which the Association can be of use to exhibitors, and beyond those mentioned, is the matter of insurance, regarding which the Association's expert wishes to point out to members the necessity of making special arrangements jointly.

The South London Single-Phase Railway.—We are officially informed that there is no truth whatever in the statement made in some of the daily papers on Tuesday that the opening of the single-phase railway between Victoria and London Bridge has been delayed owing to difficulties with the Board of Trade with reference to provisions for public safety in the matter of signals. The Board of Trade is absolutely satisfied with all the arrangements in connection with the line, and unforeseen delays in the completion of certain work, coupled with the bad weather, is alone responsible for the opening day having to be postponed, possibly until December 1st.

SOME NEW DESIGNS OF VERTICAL MOTORS

THE increasing tendency to adopt the direct-drive is responsible for many modifications in the design of electric motors. Not a few of these have exerted a marked influence on the conduct of certain industrial operations. One of the most noteworthy is that the development of the vertical motor, particularly in the field of pumping on a large scale. The use of motors fitted with a vertical shaft was formerly solely confined to a few isolated cases, owing to the fact that the driving of machinery which on account of its design would have necessitated a motor fitted with vertical shaft was usually accomplished by means of ordinary motors with horizontal shaft by interposing suitable gearing. The simple process of inverting the electric motor, which is so readily effected, has in the case of the centrifugal pump been responsible for a similar alteration in its design and construction. But for the vertical electric motor industry, the vertical rotary pump would not have been developed, for no other power agent is so convenient or so compact for the purpose as the electric motor.

Electrically-driven rotary pumps possess many advantages over reciprocating pumps, especially for mines and collieries, in the direction of flexibility, economy, reliability, and durability. A higher lift can be dealt with by a single pump, and the higher speed of the centrifugal pump thus enables a motor of smaller dimensions to be used than would be necessary with a reciprocating pump. The compact sets obtainable are also adaptable to the most difficult working conditions in narrow shafts. When sinking a shaft in which the pump has to work directly under water, which is only in the rarest cases, it is necessary to use a totally-enclosed motor of the watertight type, the size of which will, therefore, be much larger in comparison with its output than would otherwise be the case. In the majority of cases, this is not necessary, as the "drip-proof" type of motor affords sufficient protection against the moisture. This protection is solely attained by means of a non-drip hood fitted above the motor frame, which throws the water off the machine and does not permit any dropping water to gain access to the interior of the motor itself. The motor is of the fully ventilated type, and the windings are specially impregnated in order to afford extra protection against the humidity of the atmosphere. The Felten & Guilleaume-Lahmeyerwerke have, in addition to their standard types of horizontal motors, developed a series of vertical patterns specially suitable for the operation of machine tools and centrifugal pumps, some of which are briefly indicated below.

The three-phase slip-ring type induction motor, shown in Fig. 1, installed at the Mont-Cenis colliery, Sodingen, has an output of 28 h.p. at 120 volts and 1,450 r.p.m The pump is of the single-stage type, delivering 26,400 gallons of water per hour against a head of 147 ft., and is connected with the motor by a flexible coupling. The top bearing of the motor has been designed as suspension bearing, and supports the rotor, the lower bearing simply serving to guide the shaft, while the pump has its own bearings, so that each machine is practically free to run in its own bearings, and any risk of defective alignment between the two is avoided.

In consequence of the absence of all sliding contacts, three-phase motors fitted with squirrel-cage rotors are often even more suited to the driving of centrifugal pumps, especially for the driving of sinking pumps than those of the slip-ring type. Special starting devices are, however, required, mostly of the auto-transformer type, but special leads to the rotor are totally dispensed with.

Fig. 2 illustrates a large motor of this type, which serves for driving a high-pressure centrifugal pump made by Messrs. Sulzer Bros., of Ludwigshafen-on-the-Rhine, and is installed at the Zeche Ewald, Herten, Westphalia. As this motor does not work under water, the drip-proof type could be utilised, as this provided sufficient protection. It develops an output of 185 h.p. at 500 volts and 1,500 r.p.m, starting being effected by means of an oil-immersed auto-transformer. The method of lubrication of this motor is worthy of note. A rotary pump in the circular chamber above the top bearing is driven by the the motor shaft, and pumps oil from a vessel contained in the base of the motor through a side tube. After passing through the bearing, the oil flows through a channel, arranged between the shaft and the rotor spider, to the lower bearing, and finally finds its way back to the reservoir. The overflow from the top bearing is also conducted to the reservoir through a pipe at the opposite side of the motor. The capacity of the reservoir is about 4½ gallons, and thus the oil continually remains cool. The motor is ventilated by means of a fan mounted on its shaft. Air is drawn in through circular holes in the motor base, and after passing through ducts provided in the stator and rotor, is expelled through the openings under the drip-proof hood.

Fig. 3 illustrates a ready mounted sinking pump delivered to the Gabriela Mine, Brandau, Bohemia. The water-tight motor is of the short-circuited rotor type, and develops an output of 42 h.p. at 500 volts and 2,900 r.p.m. The connection between the pump and the motor is well cushioned with rubber rings, as it frequently happens that the pump has to work entirely under water. The top bearing of the motor is constructed as a suspension bearing and supports the rotor, while the lower journal bearing simply serves to guide the shaft,

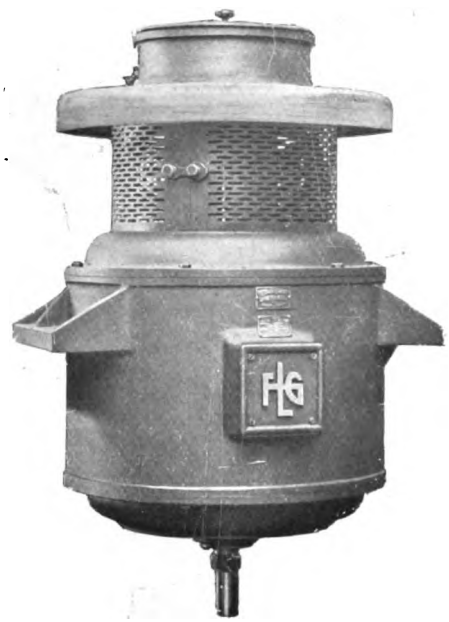

Fig. 1.—28 h.p. Vertical Three-phase Motor.

Fig. 2.—Vertical Drip-proof Three-phase Squirrel-cage Motor, with forced lubrication.

Fig. 3.—Electrically-driven Sinking Pump.

Digitized by Google

the pump possessing its own bearings. The motor terminal box is also made water-tight, and the leading-in cables are thoroughly bushed with rubber. Lubrication of the top suspension and guide bearing is effected automatically. Oil, contained in a reservoir, which totally encloses the lower journal bearing, travels along a transporting worm cut in the motor shaft through a special channel, also provided in the shaft, to the top bearing, and returns to the reservoir through the pipe seen at the side of the motor.

One of two equally large pumping plants which are installed in the pits of the Bergbau A.-G. at Friedrichssegen is shown in Fig. 4. The pumps serve for draining the pits, which have already stood under water for many years. The motor, of the drip-proof type, has a continuous output of 75 h.p. at 3,000/2,880 r.p.m., and is operated from a 500-volt circuit. Lubrication is effected in an exactly similar manner described for the motor illustrated in Fig. 5. The mechanical connection between the motor and the frame of the pump is made by means of a connecting-piece, and both shafts are joined by a flexible coupling, which takes up any axial thrust. The motor is direct-coupled to a five-stage high-pressure turbine pump, made by Messrs. C. H. Jaeger, of Leipzig-Plagwitz, which delivers 13,400 gallons of water per hour against a head of 689 ft. The rotor and guide wheels of the turbine pump are made of bronze, and the shafts of nickel steel. As will be seen from the illustration, the whole pumping plant is self-contained in a strong, especially reinforced channel iron suspension frame. An iron ladder has also been provided, by means of which all parts of the machinery are made easily accessible.

The motor illustrated in Fig. 5, a three-phase squirrel-cage high-tension motor of the flame-proof and watertight type, has been delivered to the Société de Fonçage de Puits Franco-Belge for direct-coupling to a "Sulzer" high-lift centrifugal sinking pump. The over-all dimensions of this motor are particularly small, the outside diameter being only 29½ in., and the height 62½ in. It develops a continuous output of 95 h.p. at 2,000 volts and 3,000/2,880 r.p.m. This motor is provided with automatic lubrication, each bearing possessing its own and entirely independent oil circulation. The pipes seen in the illustration serve for conducting the water for cooling the stator frame, the top suspension and top guide bearing. These pipes are directly connected to the lowest pressure stage of the centrifugal pump itself. The three pipes to be seen on the right-hand side of the motor serve for discharging the cooling water. It is only by means of this very efficient system of cooling that it was possible to construct and place upon the market a totally-

FIG. 8.—WATER-TIGHT VERTICAL CONTINUOUS-CURRENT MOTOR, WITH BALL BEARINGS.

Digitized by Google

enclosed motor for large outputs having the above-mentioned comparatively small dimensions, thereby rendering it suitable for working in the narrow shafts of mines.

In addition to three-phase motors, which, owing to their simple design and absence of sensitive parts, are generally given the preference, continuous-current motors, which may be equally well constructed with vertical shafts, may also be taken into consideration for this class of work. In some cases, even, and especially when the question of speed regulation arises, as with the driving of hydro-extractors, etc., direct-current motors are to be preferred.

Another continuous-current shunt motor developing an output of 17 h.p. at 110 volts and 1,100 r.p.m., is illustrated in Fig. 6. As this motor is at work above ground, it was not found necessary to provide it with a special protecting cover for the winding. In Fig. 7 a vertical continuous-current shunt motor constructed by the Felten & Guilleaume-Lahmeyerwerke A.-G., is illustrated. The motor is of the drip-proof type, and has been provided with a cooling device. It is at work in the Braunkohlengrube Concordia in Nachterstadt, where it drives a centrifugal shaft-sinking pump made by the Maschinenfabrik G. Bölte, Oschersleben. The normal speed of the pumping plant is 970 r.p.m., although the speed may be varied between 640 and 1,120 r.p.m. by field regulation. The output of the motor is 55 h.p. at 1,120 r.p.m., 40 h.p. at 970 r.p.m., and 18 h.p. at 640 r.p.m., the pressure of the supply being 440 volts. An interesting continuous-current shunt motor is depicted in Fig. 8. This motor is fitted with ball bearings, and serves for driving a centrifugal pump made by the Maschinenfabrik "Cyclop," Mehlis & Behrens, Berlin, at the Buch power station, near Berlin. Two motors, having an output of 7·2 h.p. at 440 volts and 2,100 r.p.m., and 14 h.p. at 440 volts and 1,650/1,980 r.p.m. respectively, are installed in this plant. They are both entirely enclosed and watertight as it frequently happens that the motors have to work when entirely under water. The lubrication of the bearings takes place in a similar manner to the method previously described, with the exception that the oil pump and reservoir are fitted at the top of the pit instead of being contained in the motor housing. The pipe seen in the illustration serves to convey the oil from the top to the lower bearing. The frame of the motor is further totally enclosed in an iron mantle, in the interior of which water is kept constantly circulating. The connection pipes, not shown in the illustration, are connected to the lowest step of the pump in exactly the same manner as those in the cooling arrangement for the motor shown in Fig. 5.

We are indebted to the Felten & Guilleaume Lahmeyerwerke A.-G. for the above particulars and for the loan of the blocks illustrating these motors, all of which are manufactured by them.

THE TROLLEY 'BUS

ON Saturday the members of the Municipal Tramways Association, attending the conference in London, were present at a demonstration given by the Railless Electric Traction Co., Ltd., at the Hendon depot of the Metropolitan Electric Tramways. An arrangement was entered into in the early part of this year between the two companies under which the Metropolitan Electric Tramways, Ltd., have constructed an experimental road with the necessary overhead equipment, and a car supplied by the Railless Traction Co. is now undergoing trials. The Metropolitan Electric Tramways, Ltd., expect that they will find considerable use for the system, and it will be noticed from the destination board shown in the photograph of the experimental car in Fig. 1, that a possible route is that between Golders Green Station and Hendon.

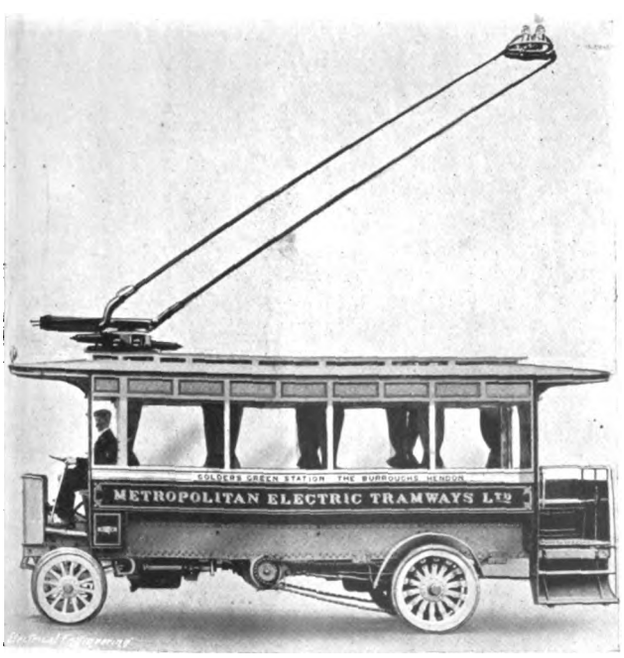

FIG. 1.—GENERAL VIEW OF EXPERIMENTAL CAR.

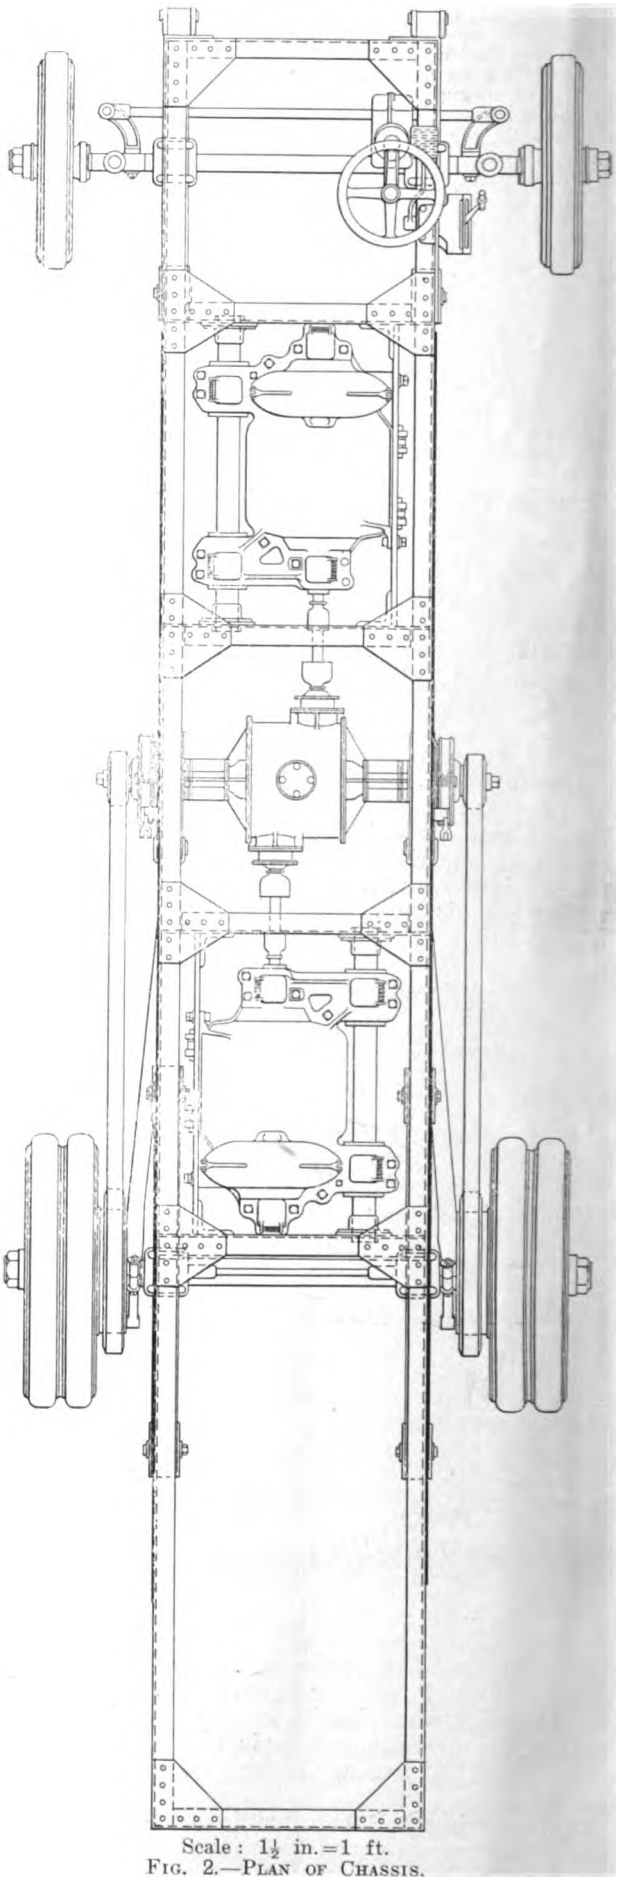
The experimental car has seating capacity for twenty-four persons, and weighs, exclusive of passengers, about six tons. It is, however, unnecessarily heavy, and several modifications are to be made which will reduce the weight considerably. In its general features the chassis follows the lines of motor omnibus design, but the side channels are strengthened by vertical plates, and the framework stiffened by cross channels. Two designs have been prepared, in both of which the rear wheels are independently chain-driven from the two ends of a countershaft. The first design requires only one motor, which is placed with its axis parallel to the centre line of the car, and drives both ends of the countershaft through differential gearing. In the second design, illustrated by the plan of Fig. 2, there are two motors, also placed with their axes parallel to the length of the car, one in front of and the other behind the countershaft, each motor driving one-half of the countershaft through a bevel gear. The two motors are thus mechanically independent, and each drives one of the rear wheels. The chassis of the car in question was designed and constructed by Messrs. James & Browne, Ltd., of Hammersmith, for the Railless Electric Traction Co. The two motors are of the standard B.T.H. traction pattern, G.E. 54A, and develop 25 h.p. each on a one-hour rating, a much larger output than that really necessary for a car of this size. As can be seen from Fig. 2, the motors are fixed to the frame, and drive through universal joints. Reynolds silent chains are used for the chain drive.

The controller, which is of the standard B.T.H. pattern, is fixed under the driver's seat, and operated by a lever working over a notched quadrant. The usual leakage indicator is also provided. Foot and hand brakes on both the driving wheels and countershafts are supplied.

The two motor design has the advantage of series-parallel control, but this may not be of such importance for a road vehicle as for a tramcar. The road resistance of a railless trolley car bears a much higher proportion to its weight than does rail-resistance to the weight of a tramcar. Consequently, the energy consumed by a railless car in overcoming its inertia during acceleration bears a much smaller proportion to the total energy consumed in completing a given cycle of operations than is the case with a tramcar. Thus, series-parallel control, which reduces the energy expended during acceleration, may effect no appreciable economy in the over-all consumption in this case. Series-parallel control, however, provides a second efficient running speed which is often of service in crowded traffic. The second design also enables a car to return to the car sheds without external assistance, should one motor be burnt out or damaged while in service, as means can be provided to couple the two counter-shafts together mechanically.

A matter of importance is the fact that the metal frame of a railless car is completely insulated from earth by its rubber tyres, and might become charged to the full line voltage above earth if the insulation of a cable or other portion of the circuit should be defective. Continental engineers have so far ignored this

Digitized by Google



danger, and have placed full reliance upon the insulation of the motor circuit. In the present car, however, the steel framework and other metallic parts of the car are always in electrical connection through one or other of the trolley wheels, with the negative or earthed trolley wire.

Under these conditions, it is essential that whichever trolley wheel is selected for this purpose must not be capable of coming in contact with the positive trolley wire. This requirement is completely fulfilled only by the use of a special trolley head and three trolley wires, of which the two outer wires are positive and the centre wire negative. Three trolley wheels are mounted on a single rotatable head, the two outer wheels, which are connected together, making contact with the outer or positive wires, and the inner wheel with the centre or negative wire. To ensure that the inner wheel may not under any circumstances come in contact with either of the positive wires, the negative wire is supported at an elevation of several inches below the positive wires, and the negative trolley wheel is mounted in a corresponding position relative to the outer wheels. In order to ensure accurate spacing of the trolley wires, the three conductors are supported by a triple hanger, which may be made either in one piece, or in three separate parts bolted together. If the latter arrangement is adopted, and if at a later date it is decided to equip the route as a tramway, it is only necessary to take out the bolts in the hanger, remove the centre portion with the centre wire, and slide the two outer portions with their trolley wires to any desired position on the span wire.

As the three trolley wires may be objected to on the ground of expense or unsightliness, a design in which there are two trolley wires only, some 7 in. apart, one acting as positive, the other as negative conductor, has been developed, and the equipment at Hendon is of this pattern, although triple hangers are used so that the three-wire arrangement can be experimented with later. The positive and negative trolley wheels are mounted as before on a common rotatable head, the construction of which can be seen from Fig. 3. The framework of the car, instead of being directly attached to one of the trolley wheels, is brought to the middle of a single-pole double-throw switch, by which it can be connected at will to either one or the other trolley wheel. A polarised relay is mounted on the car, one coil of which is energised by the trolley circuit, the other by a small storage battery. When the single-pole switch is in the correct position to connect the framework of the car to the particular trolley wheel which is at that instant in contact with the negative or earthed conductor, the relay is inoperative. But should the polarity of the trolley wires be for any cause reversed, the relay instantly brings into action an electric hooter, mounted in the front canopy of the car. The hooter continues in action until the driver reverses the switch and thereby transfers the connection of the framework to the other trolley wire. In conjunction with this apparatus is a second hooter, which notifies the driver of a breakdown in the insulation of the motor circuit. A device for effecting the change-over automatically is now being developed. At each end of the experimental track at Hendon, there is a loop, and when the trolley passes the junction of the wires after completing the loop, the polarity is reversed. Each time this occurs, the hooter sounds, and the driver changes over the switch.

The trolley head is of the under-running type, carried at the end of a rigid boom and kept in contact with the overhead conductors by raising-springs in the trolley base. In order that the trolley head shall remain in contact with the overhead conductors under all conditions of service, and shall permit of sudden and wide diversions of the car on either side of the centre line of the wires, without diminution of speed, a special trolley base has been designed, in which, besides the usual raising-springs, there are additional springs working in a horizontal plane and controlling the pivot of the trolley base in such a manner as to relieve the trolley wheel of excessive side-pressure against the trolley wire, even when the car is running at some distance from the wires. This is effected by arranging the springs so that the wider the angle subtended between the pole and the car, the greater the leverage of the springs on the pole and the greater the effective pressure outwards.

Instead of a single trolley wheel, a pair of wheels is used for making contact with each of the trolley wires. Each wheel is capable of a slight axial movement, and the pivot upon which it is mounted is free to move vertically, being pressed upwards by a coiled spring. By this means any small inequalities in the elevation or horizontal spacing of the wires are overcome. The trolley pole is made up of two separate poles which form two sides of a parallelogram, of which the two ends are the trolley base and the head respec-

Scale: 1½ in. = 1 ft.

FIG. 2.—PLAN OF CHASSIS.

Digitized by Google

tively. The head, therefore, always remains parallel to the base, and, in consequence, approximately parallel also to the surface of the roadway. The mean length of the pole is 16 ft. 6 in., which allows the car to have an extreme range of travel of 17 ft. to either side of the centre of the road, measured to the outer wheel.

By a socket and plug attachment, the head may be converted into the usual single-pole trolley head, which can be used for running the car along the route of an existing tramway line. The return circuit is in this instance provided by the rails, to which connection is made by a pair of slippers, which are suspended from the rear platform of the car, and travel in the groove of the rails. The suspension is effected in such a manner as to permit the car to deviate several feet on either side of the centre line of the track.

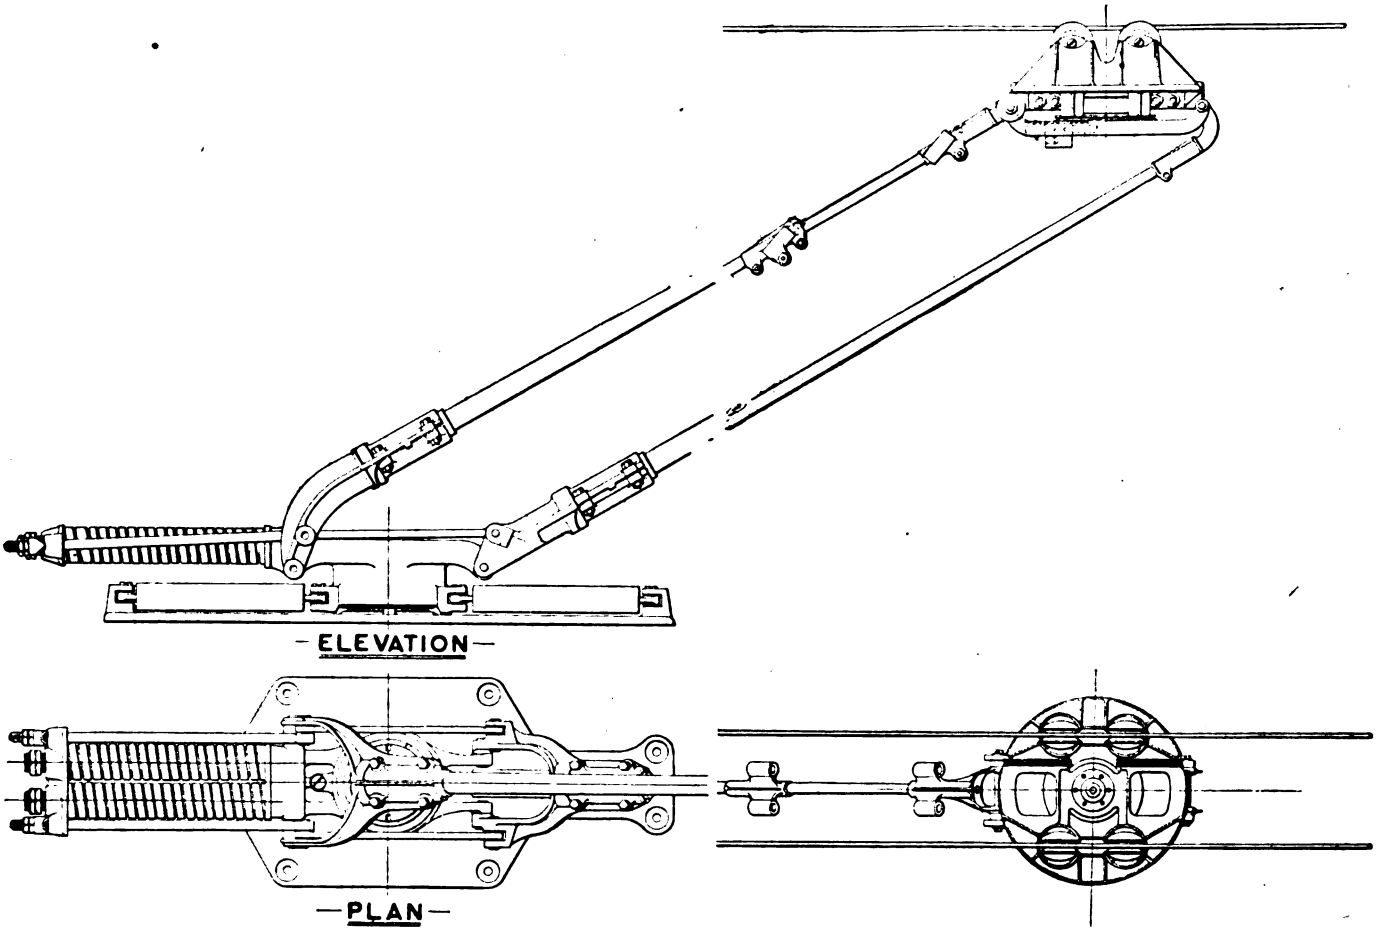


FIG. 3.—NEW DESIGN OF TROLLEY POLE, BASE, AND HEAD FOR TWO-WIRE LINE.

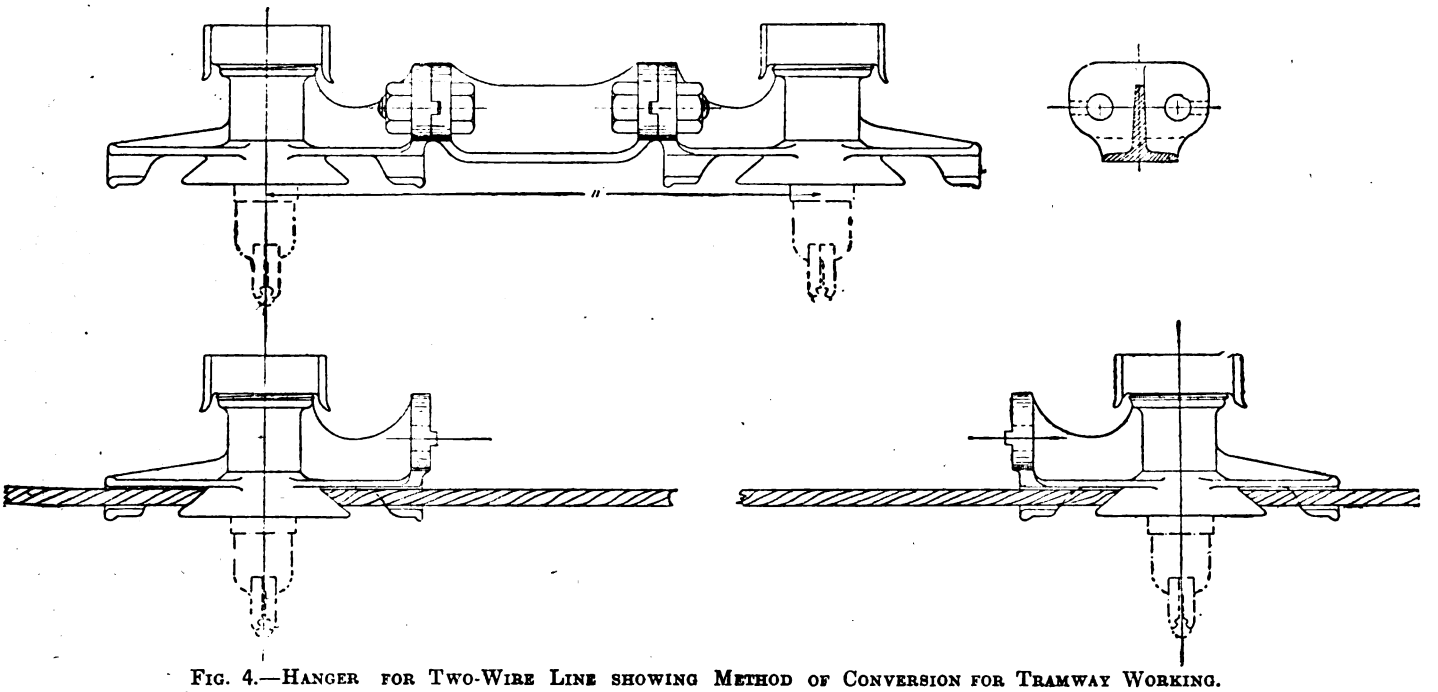

FIG. 4.—HANGER FOR TWO-WIRE LINE SHOWING METHOD OF CONVERSION FOR TRAMWAY WORKING.

We are informed that it is possible with the above design of pole and head to maintain contact with the trolley wires with a pressure of only 10 lbs. on each wheel and under the severest conditions of service. It should be mentioned that the trolley pole shown in the photograph of Fig. 1 and in use on the car at Hendon has been superseded by that illustrated in

Digitized by Google

Fig. 3, which is lighter and of better appearance. The illustrations of Fig. 4 show the pattern of hanger designed for a two-wire line. It will be noticed that this also can be divided into two parts by taking out the central connecting link, and thus by sliding the halves along the supporting wires can be converted for normal double track tramway running. The overhead line fittings used at Hendon, the trolley pole, base and head, and the relay and hooting device were constructed by Messrs. Brecknell, Munro & Rogers, of Bristol.

There are some heavy gradients on the experimental road at Hendon, and the car negotiated these fully loaded without any difficulty on Saturday. A fair speed was also attained on one portion, although the shortness of the road and the sharp curves do not allow of the maximum speed of which the car is capable being reached.

The man in the street will require a name for the new vehicle, for he will kick at "railless traction car" or "trackless trolley car." May we suggest "trolley 'bus," which has the additional advantage of being an accurate description.

PROPOSED TUBE RAILWAY TO THE CRYSTAL PALACE

THE announcement has been made of the intention to deposit a Bill in Parliament next session seeking powers to construct a tube railway from Victoria to the Crystal Palace. In 1902 a proposal was made for the construction of such a railway with the London terminus near Cheapside, but the Bill was not proceeded with, the capital involved being £5,000,000. Some particulars of the present proposal from Victoria to the Crystal Palace were given in the *Standard* of Saturday, a correspondent of which newspaper has had an interview with Mr. Stephen Sellon, who has prepared the estimates of the cost of construction and revenue. The capital of the company is to be £3,500,000, and the cost of construction is put at the low figure of £340,800 per mile, including land and equipment. The reasons put forward for taking this low figure, which is nearly half the cost of the existing tube railways in London, is that there are a number of expensive contractors' plants lying idle, and that, in addition to taking advantage of past experience, the work will be paid for in cash at competitive prices. The line will start from Upper Norwood (Crystal Palace Parade), and stations will be at or near the following points:—Upper Norwood, Upper Sydenham, Lordship Lane, Dulwich, East Dulwich, Denmark Hill, Camberwell, Oval (connecting with City and South London Railway), Albert Embankment, and Victoria. The length of the line will be 6¾ miles, but in addition it is proposed to construct a branch from Camberwell to the Elephant and Castle. The station at Victoria will be designed to provide for through communication with the North-West London Railway when this is constructed.

Estimates of revenue have been prepared showing a gross annual revenue of £500,000, with a net revenue of £159,000, the working expenses being taken at 47 per cent. The number of passengers required to be carried to earn this net revenue is estimated at 4,364,000 per mile, which is slightly over half the number carried by the Baker Street and Waterloo Railway last year. It is further stated that several of the largest financial houses in the City are behind the promoting syndicate.

WIRELESS TELEGRAPH NOTES

In the House of Commons on Thursday, Mr. Lupton asked the Postmaster-General if he was proposing to buy the Marconi wireless telegraph stations, and, if so, at what price; if a trans-Atlantic wireless station could be erected for £15,000 or less, and an ordinary shore-to-ship station for £3,000; if he was aware that there were several other methods of wireless telegraphy, the inventors of which allege that messages can be sent more rapidly, with greater reliability, and to greater distances than by the Marconi system; and whether, seeing that the science of wireless telegraphy was still comparatively in its infancy, he would take care that there was no interference with perfectly free competition between the various systems. The Postmaster-General said that the matter referred to in the first part of the question was under negotiation with the Marconi Co. and Lloyd's. If and when he came to a satisfactory conclusion, he would make a statement to the house. With regard to free competition between the various systems, he could at once give the desired assurance.

An American Consular report states that the Brazilian Government has made a contract with a French telegraph company for the construction of a wireless station on the island of Fernando Noronha, 200 miles east of the coast of Rio Grande do Norte, and 400 miles from Pernambuco, the nearest large Brazilian port, with auxiliary stations at Pernambuco to connect the island station with the Brazilian telegraph system, and at such other points as may be needed. The island station will have a range of 1,000 miles, approximately half-way across the Atlantic from that point, and reaching as far south as Bahia and as far north as Maranhao.

The United Fruit Co., of Boston, has undertaken to establish wireless stations at Colon and Bocas del Toro.

It is announced that the principal ships of the Japanese Navy, which are already equipped with wireless telegraph apparatus, are now to be fitted with Professor Nissuno's wireless telephone system.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

CONTINUOUS-CURRENT MACHINES.—A new series of continuous-current motors and generators of small size, ranging up to about 36 h.p., is described in a list just issued by the British Thomson-Houston Co. (Rugby). These machines are compactly arranged with cast-iron frames and laminated poles, and the nature of the end covers permits of fixing to wall or ceiling while retaining ring lubrication. The ordinary protected type can have added to it perforated or expanded metal covers, or can be totally enclosed by means of solid covers, and in the last case forced ventilation can be arranged for by an internal fan mounted on the armature shaft. Special flame-proof covers can also be supplied. The list contains full details of standard outputs and speeds for all these arrangements, and a full specification of the construction of the machines.

STORAGE BATTERIES.—The new export list of the Tudor Accumulator Co. is a very handsomely got-up publication, and besides full descriptions and illustrations of the various patterns of cell made by the company, contains a good deal of useful data, which will enable battery schemes to be drawn up, including typical estimates, fully worked out, with details of all essentials of a complete battery plant. A number of complete Tudor batteries and single cells of large size are illustrated, and a view is given of the company's works at Dukinfield, Manchester.

LAMPS, SWITCHGEAR, AND ACCESSORIES.—Messrs. Drake & Gorham, Ltd. (66 Victoria Street, Westminster, S.W.) are issuing a new catalogue, which is well-arranged and printed, and covers a wide ground. The place of honour is occupied by metal filament lamps, and full particulars are given of the sizes, patterns, and prices of Osram and tantalum lamps. The next section deals with arc lamps, among which is that of Messrs. Drake & Gorham's own design, described in ELECTRICAL ENGINEERING, September 9th, 1909, p. 805. The firm's auto-transformers for metal filament lamps are also listed. A number of pages are devoted to steel conduit tubes and fittings, and the ingenious two-part porcelain insulators for fastening cables to walls are also illustrated. In this insulator one screw both binds the cable and fixes the insulator, rendering binding wire and insulating washers unnecessary. Several pages are devoted to switches, fuse and distribution boards, and typical switchboards erected by the firm. Full particulars are given of the Bastian quartz radiator, described in ELECTRICAL ENGINEERING, July 8th, 1909, p. 631, and the catalogue concludes with a very complete list of electric light fittings and accessories. Amongst these are some special watertight fittings, cargo-light fittings for ships, holophane and fancy glassware for metal filament lamps, reflectors, and ventilated lanterns of the "Phœnix" pattern for street, station, and shop-window lighting. A special vibration absorber for use in "Phœnix" lanterns is also listed.

GALVANOMETERS.—A booklet containing full particulars of the various patterns of Clark Fisher galvanometers and various accessories for use with these, is to hand from the Reason Manufacturing Co., Ltd., of Brighton. We hope to publish descriptions of some of these instruments in a future issue.

ELECTRICALLY-DRIVEN TOOLS AND WINCHES.—Two leaflets received from the Witton-Kramer Electric Tool & Hoist Co. (Witton, Birmingham), describe some new types of electric grinders and polishers with self-contained motors. Among these are a tool-post grinder, suitable for the compound slide rests of lathes and milling machines, and a "long snout" grinder, with longitudinal feed, for internal grinding or for grinding the commutators of large machines whilst the armature is in position. For this purpose it is usually fitted with a cross-traverse movement, in addition to the longitudinal feed. A third leaflet gives particulars of the "Witton-Kramer" flexible shafts for operating tools from portable motors. These consist of a core made up of many layers of steel wire wound in alternate directions. This core runs in a flexible casing made of square wire which serves as a bearing throughout its whole length. The casing has either an outer covering of leather or is protected by a flexible metallic tube lined with hardened and tempered steel wire. The casing ends are fitted with phosphor bronze bearings for the core ends. Another leaflet describes the firm's electric winches.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 23rd, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

18,115/08. **Regenerative Primary Cell.** J. SPILIOTOPOL. In this cell, both the depolariser and the negative electrode are restored to the condition previous to the discharge of the cell, by heating. The electrolyte contains chromium sesquichloride; the positive electrode is carbon, and the negative electrode is aluminium, which dissolves in the electrolyte when heated to 100° C. Manganous chloride is used as the depolariser. The cell must be air-tight, so that no gases escape. Under these conditions, a continuous reversible cycle of reactions is said to be possible, so that the cell gives a means for the direct conversion of heat into electricity. Five claims.

22,627/08. **Heating Units.** G. COOPER and F. C. SHARP. This specification describes the fixing of connecting wires to silundum rods by compressing the connecting pieces of metal round the rods while the metal is in the plastic state, and maintaining the pressure during cooling. For example, iron sockets can be cast round the ends of the rods under pressure, or pieces of wrought iron can be pressed round the ends at a red heat. A good contact is obtained over a large surface in this way, and the sockets can be of such a length that the parts where the connecting wires are attached will be comparatively cool. Two claims, eight figures.

23,111/08. **Crane Control.** E. M. HOLME. This is a system of control particularly adapted for cranes used for loading and unloading ships, in that the main controller is actuated by solenoids as in a lift controller, by means of a flexible cable and a portable switchboard situated in any position on or off the ship giving a clear view of the operations. Four claims, five figures.

26,685/08. **Portable Drilling Machines.** SIEMENS BROS. DYNAMO WORKS, LTD. This invention relates to portable drills with self-contained motors and either screw arrangements for feeding the drills forward or a breast plate. The casing or framework is divided into two parts in the plane of the axes of the shafts of motor, drill-driving spindle, and counter-shaft. All the moving parts are thus readily accessible, and when the casing halves are bolted together, the shafts are held firmly in position, and the spur wheels kept in proper register. Further, the driving spindle has a hollow portion which contains the feed screw, and is encircled on the outside by a bearing. Three claims, four figures.

4,705/09. **Balanced Transformer Protection System.** ALLGEMEINE ELEKTRICITÄTS-GES. In protective systems in which the secondaries of two transformers are balanced against one another in a closed circuit, the secondaries are shunted by overload relays the contacts of which are in parallel in the tripping-coil circuits of the main circuit breakers. As an alternative, the primaries of the transformers which are in the circuit to be protected, are shunted by resistances which will maintain the balance at a momentary overload, but which upset the balance if the overload exists sufficiently long to heat them up. Two claims, two figures.

15,725/09. **Track Brakes.** WESTINGHOUSE ELECTRIC CO., LTD. Ordinary track brakes are not maintained vertically above the rail-head when the vehicle is rounding curves, and thus efficient braking is prevented, especially in vehicles of long wheel base. According to this invention, the track brake is mounted upon a travelling support flexibly connected with the vehicle frame, and provided with two guide wheels, so that the brake shoes are always maintained at the same height vertically above the rails. As an alternative, one end of the support may be hung from a main axle, the other end being supported on a single guide-wheel. Three claims, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BEAVER and CLAREMONT [Aerial cable] 28,485/08.

Dynamos, Motors, and Transformers: LEITNER [Automatic voltage control] 19,223/08.

Electric Ignition: PENROSE [Holder for sparking-plugs] 24,262/08; ROBERT BOSCH [Magneto-ignition] 25,547/08.

Electrometallurgy and Electrochemistry: BINGHAM [Electric furnaces] 26,356/08.

Heating and Cooking: BASTIAN [Heating apparatus] 19,333/08.

Incandescent Lamps: MARSH [Holders and sockets] 28,177/08; WOLTERS [Safety lamps] 10,312/09.

Switchgear, Fuses, and Fittings: WOODHALL and EMERY [Electric light fittings] 19,150/08; SIEMENS BROS. & Co. and HUDDLESTON [Clamping devices for fittings] 21,912/08; VON ZWELGBERGK [Magnetic blow-outs for switches] 25,954/08; BAKER and PEARCE [Automatic timing switch] 27,323/08.

Telephony and Telegraphy: SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*) [Telephone service registers] 10,203/09; EGNÉR and HOLMSTROM [Telephone transmitters] 12,918/09; SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*) [Telephone exchanges] 17,104/09.

Traction: MOUNTAIN & GIBSON, LTD., and PRINGLE [Joining and anchoring rails] 18,857/08; BROWN [Signalling] 18,996/08; ORMSTRON and CHARLTON [Overhead trolley conductors] 20,647/08; DIXON [Brakes] 10,199/09.

Miscellaneous: FAIRWEATHER (*Huff Electrostatic Separator Co.*) [Separators] 16,583/08; CASTLE [Fire alarms] 22,119/08; MILLS (*Maschinen und Dampfkesselfabrik "Guilleaume Werke" Ges.*) [Contact device for supplying locomotive from overhead crane conductors] 28,076/08; LIDDLE (*Morgan Gardner Electric Co.*) [Coal-cutters] 10,045/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: KUNKEL [Machines] 19,394/09.

Electric Ignition: GIBAUD [Mechanism] 20,241/09.

Instruments and Meters: COMPAGNIE POUR LA FABRICATION DES COMPTEURS ET MATÉRIAL D'USINES À GAZ. [Electric induction meters] 19,277/09.

Application for Amendment

16,968/07. **Adjustable Carbon Powder Resistance.** H. S. MARTIN. The Electrical Regulators and Economisers, Ltd., seek leave to amend this specification. The patent is for a resistance comprising a mixture of graphite powder, mica scales, and sand, under a variable pressure. The mica scales give the necessary elasticity to decrease the conductivity when pressure is removed. The addition of substances which become conductors when heated to a certain temperature, is also covered. The desired amendment consists in striking out the description of a special construction of the device, and of means for varying the pressure and the area of the conducting surfaces, as well as claims 4, 5, and 6 referring to this.

Opposition to Grant of Patent

14,615/08. **Dry Cell.** H. HUNTE. Opposition has been entered to the grant of this patent. The claims are for a dry cell with one or more vertical air-passages through the depolariser in communication with the outside air at both top and bottom. The depolariser consists of manganese peroxide, lead peroxide, sulphuric acid, plumbago, ammonium chloride, and zinc chloride in prescribed proportions. This is made into a stiff paste and pressed round the carbon cathode. The whole is wrapped round with a fabric material coated with a paste of flaked rice, zinc chloride, and ammonium chloride in certain proportions, and enclosed in the zinc anode in the usual way.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: BRITISH THOMSON-HOUSTON Co. (*R. Fleming, U.S.A.*) [Enclosed A.-C. arc lamp] 13,010/98; B. M. DRAKE and J. M. GORHAM [Carbon for gravity feed against a stop] 11,881/05; CROMPTON & Co. and E. W. ABBOTT [Hoisting, locking, and lowering gear] 11,967/05; O. D. LUCAS [Mercury vapour lamps] 12,087/05.

Distributing Systems, &c.: BRITISH THOMSON-HOUSTON Co. and E. B. WEDMORE [Cable coupling or switch terminal] 11,970A/05; J. MEYENBERG [Insulating composition] 12,105/05.

Dynamos, &c.: BRITISH THOMSON-HOUSTON Co. (*E. W. Rice, U.S.A.*) [Equalising connections for rotary converters] 13,970/97; R. BRAUN [Flywheel load equaliser] 11,821/05.

Heating and Cooking: H. DOWSING [radiators] 13,180/04.

Incandescent Lamps: J. R. CRAWFORD [Filaments of carbides of earth metals and refractory metals] 13,253/04.

Instruments and Meters: BRITISH THOMSON-HOUSTON Co. (*C. P. Steinmetz, U.S.A.*) [Three-phase motor meter] 13,977/97.

Switchgear, &c.: H. LEA [Adjustable lamp fitting] 13,169/04; F. AGAGGIO [Quick-acting push for high-pressure bells] 11,770/05; E. J. OVERELL [Telescopic lamp bracket] 11,813/05; H. E. SAXBY [Plug connector] 12,003/05; A. W. PENROSE [Limit switches for lifts] 12,024/05; G. E. FLETCHER [Rheostat arm with step motion] 12,062/05.

Telephony and Telegraphy: S. G. BROWN [Relays] 13,015/04; ELECTRIC & ORDNANCE ACCESSORIES Co. and R. F. HALL [Intercommunication telephone switch] 13,107/04; I. KITSEE [Siphon recorder] 11,745/05.

Traction: P. COUPETTE [Station indicator] 12,768/04; C. W. G. LITTLE [Trolley arm] 13,274/04.

Miscellaneous: K. W. HEDGES [Lightning conductors] 11,584/01; A. C. COSSOR [X-ray tube] 11,829/05; A. J. BOULT (*Phönix Elektrotechnische Ges.*) [Electrically worked moving targets] 11,860/05; C. H. O'BRIEN [Sound-emitting vibrator] 11,921/05; G. J. JACKSON [Indicating failure of lamp] 12,100/05.

Digitized by Google

LOCAL NOTES

ACTON: *The Electricity Undertaking.*—At the last meeting of the District Council, the following motion was passed:—"That the maximum demand system, based on the load factor for power and heat, would be fairer to the Council and the consumers than the flat rate now in force, and that it be referred, together with the Engineer's report, to the Electricity Committee to fix the charge." A resolution was also moved that negotiations be reopened with the Metropolitan Electric Supply Co., for the taking over of the undertaking, and that in the event of certain replies of the company being favourable a referendum of the ratepayers be taken on the question of disposing of the undertaking. Six voted for the motion and six against; it was therefore not carried.

BERLIN: *Failure of Supply.*—On Monday night the electric supply in part of the Friedrichstrasse was interrupted for some hours, owing to a fault in a feeder cable. It was midnight before the supply was restored.

BOLTON: *Feeder Pillar Accident.*—A runaway horse and lorry collided with a feeder pillar in John Brown Street on Friday and considerably damaged it. The feeder pillar in question was in connection with the 6,000-volt supply to the works of Messrs. J. Musgrave & Sons, Ltd., and Messrs. Dobson & Barlow, and the supply to these two firms was interrupted for a short time.

BRADFORD: *Central Tramway Depot.*—Hitherto the tramway depots of the Corporation have been of a somewhat temporary character, and it has become necessary for the Corporation to face the prospect of erecting permanent buildings on all the present sites, or of adopting a scheme of the manager for the provision of one central depot. A suitable site in the Longlands area is available for this latter purpose, and Mr. C. J. Spencer has calculated that if a depot were erected there a saving of 56,394 car miles per annum of "dead mileage" would be effected. At present there are nine depots, and they provide storage for 275 cars. If the present policy is continued an outlay of £22,468 on new depots will have to be provided for, and it is claimed that the saving in dead mileage and in administration with a central depot would amount to £1,787 per annum, which represents a capital sum in providing interest and sinking fund of £29,783. This, added to the £22,468, amounts to £52,251, whilst the acquisition of the Longlands site and a building to accommodate 150 cars, would cost £46,500. Last week the Tramways Committee visited some of the depots and considered the scheme, and it is understood they decided to recommend the City Council to adopt it.

CHILE: *Proposed Electric Railways.*—According to an American Consular report, the Chilean Government has appointed a commission to study the question of electrifying the section of the State railways between Santiago and Valparaiso, a distance of 115 miles. It is understood that an offer has been made to put in the installation, including the hydraulic electric plant, at a price that would result in considerable reductions in operating expenses over the present steam motive power, since coal is so very expensive.

CROYDON: *Effect of Through Tramcars.*—Figures have been prepared showing the beneficial financial effect of through-running between the Corporation and London County Council tramway systems. Since this arrangement came into operation there has been an increase in the takings on the Corporation tramways of £2,292 up to September 3rd. It is also noteworthy that the motor omnibuses have been compelled to cease running into Croydon from the London side.

DUNDEE: *Lighting of New Harbour.*—A complete system of electric lighting is being installed in connection with the improvements at the harbour for the docking of submarines.

GILLINGHAM: *The Electrical Undertaking.*—Mr. J. F. C. Snell has been appointed by the Council, at a fee of 150 guineas, to investigate and report upon the working and management of the electricity undertaking.

GREENOCK: *Electrical Exhibition.*—An electrical exhibition, promoted by the Electricity Department, in co-operation with the local contractors, for the purpose of demonstrating in a practical manner the advantages of utilising electrical energy for cooking, heating, lighting, and power, was held in the Town Hall last week. In order to bring the right kind of people in, complimentary tickets were issued by the department, but the demand for these became so great that a charge for admission was imposed on the last day. It is estimated that nearly 10,000 persons visited the exhibition, and hundreds were turned away in the evenings. Numerous inquiries have been received by the Corporation and the contractors, and several substantial orders were taken during the course of the exhibition, and as many other towns are considering means to recuperate from the effects of the metal filament lamp the experience at Greenock may be of some interest. A feature of the exhibition was an "electric home," and the following firms loaned apparatus: General Electric Co., Ltd.; British Prometheus Co., Ltd.; British Westinghouse Co., Ltd.; F. & C. Osler, Ltd.; the Pulvo Co., Ltd.; Verity's, Ltd.; Callenders Cable & Construction Co., Ltd.; Babcock & Wilcox, Ltd.; the Witton Kramer Co., Ltd.; Union Electric Co., Ltd.; Chinnery's Signs, Ltd.; Multi-Color Sign Co., Ltd. Lectures on and demonstrations of cooking were given.

HANLEY: *Electric Driving.*—The Corporation have acceded to a request by Messrs. Cowlishaw, Walker & Co., Ltd., that their stock of coal, which is useless owing to the whole of the works now being driven by electricity, should be taken over by the Corporation at the same price as is being paid by the Electricity Department under their ordinary contracts.

Electricity Accounts.—At the meeting of the Corporation last week, Alderman Coates, the Chairman of the Electricity Committee, presented a report upon the working of the electricity undertaking for the year to March 31st, 1909. Notwithstanding the use of metal filament lamps, the total number of units sold was 1,613,568, an increase of 141,048 units over the number sold in the previous year. The supply for motors represents one-third of the total, there being installed about 1,000 h.p. Gross receipts amounted to £14,856, an increase of £533, whilst the expenditure amounted to £8,986—a reduction of £88. The average receipts per unit were less than 2½d. After meeting capital charges there is a net profit of £415.

Electrical Lectures.—Mr. C. H. Yeaman, the Borough Electrical Engineer, has been granted permission to give a course of lectures and practical instruction under the City and Guilds syllabus in "Electrical Engineering," at the Municipal Secondary School. The use of the meter room has also been granted in connection with the course.

HASLINGDEN: *Tramway Running Powers.*—The Council propose that through running should be arranged between the tramway systems in Haslingden, Accrington, and Rawtenstall, and recommend a conference of the three authorities named. In the event of the delegates being unable to arrive at a decision, it is proposed that the Board of Trade should be asked to give consideration to the matter, their decision to be accepted by all parties.

Electric Lighting.—The Tramway Committee have referred the question of applying for an electric lighting order to a sub-committee.

HERTFORD: *Tramway Lease.*—Notice is given of the intention of the Hertford County Council to lease to the Metropolitan Electric Electric Tramways, Ltd., tramways authorised under the Light Railways Act in the parishes of Arkley, Barnet Vale, and Chipping Barnet. The lease is to be for 42 years from February 26th, 1904.

INDIA (PONDICHERRY): *Electric Lighting.*—The European portion of Pondicherry has now a supply of electricity. The overhead wires are now being extended into the native quarter.

JAPAN: *Electric Traction.*—Electric traction is to replace steam locomotives on the Hachioji-Kafu railway, and fifteen motor coaches have already been ordered.

KEIGHLEY: *Tramway Extensions.*—A proposal by the Tramways Committee that the Council should apply to the Board of Trade for a Tramways Provisional Order authorising the construction of a number of new tramways has been defeated, an amendment being carried in the Council deferring the matter for twelve months.

LEEDS: *The Railless Trolley System.*—The Corporation have decided to seek Parliamentary powers next session to instal the trackless trolley system of electric traction. The idea, at present, is to adopt the system upon the route from the City Square to Farnley, with an extension later on to Drighlington.

LINCOLN: *Tramways.*—The Eastern District meeting of the Incorporated Association of Municipal Engineers was held at Lincoln last week. Among the Papers read was one by the Borough Electrical Engineer and Tramways Manager, Mr. Stanley Clegg, which dealt with the "G. B." surface contact system of tramways in Lincoln. He said that the present average of live studs was about three per month, and owing to the short length of the line, the operation of replacing a live stud was a very easy one. No more than half an hour need elapse between the notification of a live stud and its complete replacement.

LONDON: *London County Council: Tramways.*—It is proposed to proceed immediately with the extension of the double line of electric tramways, on the conduit system, from Rainton Road, Greenwich, to the Lord Howick, Woolwich Dockyard. The necessary street widenings will cost £10,950. The completion of this work will leave about a mile of line worked by horse traction between Woolwich Dockyard and the free ferry, in connection with which further considerable street widenings will be necessary.

Hampstead: Tramways.—A large and influential deputation from the ratepayers waited upon the Borough Council last week and presented a memorial asking the Council to oppose the proposal of the London County Council to lay tramways along Adelaide Road and Finchley Road, Hampstead. The memorial, which contained 1,800 signatures, was referred to the General Purposes Committee for consideration.

A further section of new electric tramways was opened on Thursday, viz., between Bloomsbury and Stamford Hill.

County of London Co.'s New Mains.—At the meeting on

Digitized by Google

September 23rd of the Court of Common Council, the County of London Electric Supply Co., Ltd., gave notice of their intention to commence the execution of laying extra high-pressure electric mains and three 2½-in. iron conduits crossing London Bridge; along King William Street, Lombard Street, Princes Street, Moorgate Street, and Finsbury Pavement, to the boundary of Finsbury. Mr. Deputy Wilkinson said the work, which would commence on October 15th, would occupy three months, and would cause a great disturbance in the eastern part of the City. He asked what was the power of the company in the matter. The City Solicitor (Sir Homewood Crawford) said if the route suggested was disapproved of, the Corporation would have to submit an alternative one, and if that was not accepted by the company an arbitrator, appointed by the Board of Trade, would have to be called in to say what route should be taken. Mr. Turner said the question had been under consideration by the Streets Committee, and that Committee were so impressed with the importance of the matter, that they were going to call a special meeting of the Committee shortly.

MALVERN: *Metal Filament Lamps.*—During the summer vacation additions to the electrical mains have been numerous. The most important installations are the Malvern College and College master's hou es, where an installation comprising over 600 metal filament lamps has just been installed upon the advice of Mr. W. J. Rendell Baker, Electrical Engineer to the Council, who prepared all specifications, &c., the work being carried out by the local firm of Mr. A. Sparkes, under the direct superintendence of Mr. J. Houlton, engineer and manager for Mr. Sparkes.

MEXICO: *Condition of Power Company's Plant.*—Certain rumours having gained currency detrimental to the interests and prospects of the Mexican Light & Power Co., the company appealed to the Mexican Government to appoint an official engineer to report upon the accident to the Necaxa dam in May last. This gentleman has now reported that the dam was not permanently nor substantially damaged, and that the loss caused thereby amounts approximately to $500,000 Mex. (about £50,000 sterling). The works necessary to entirely finish the dam, including the repairs caused by the accident, should be completed by the end of the present year. The officials of the company in London hope that this official statement will dispose effectually of some very serious charges which have been made concerning the condition of the company's power plant, and which have been the cause of a considerable drop in the price of the company's bonds.

PORT GLASGOW: *Electric Lighting.*—A proposal for the electric lighting of the reconstructed bay area is under consideration.

ROME: *Proposed Municipalisation of Electric Supply.*—A ballot of the citizens has resulted in a majority of 25,000 votes in favour of the acquirement of the electric supply undertaking by the municipality.

SOUTH AFRICA: *Cape Town: Electric Cooking and Heating.*—The Electric and Waterworks and Fire Brigade Committee recommend that every effort should be made to popularise the use of electricity for heating and cooking purposes, on the same lines as the hire purchase of electric motors. The Committee are of opinion that an experiment should be made in cooking by electricity, and they recommend that a sum of £50 be voted for the purpose of procuring certain electrical ovens and other apparatus, with a view to tests being made.

WEST HAM: *Charge for Heating.*—Upon the suggestion of the Electrical Engineer, the rates for current used for heating purposes are to be similar to the standard rates for current supplied for power, viz., 1d. per unit, less discount for quantity.

WOLVERHAMPTON: *Church Lighting.*—A complete system of electric lighting has just been completed at St. Peter's Church. Osram lamps are employed throughout on brackets and pendants, whilst on either side of the sanctuary a line of tubolite has been placed. The work has been carried out under the supervision of Mr. C. E. C. Shawfield, the Borough Electrical Engineer.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BRAZIL.—*Commercial Intelligence* points out that there is a large and growing trade in Brazil for electric light and power machinery. British firms are not adequately represented in connection with this trade. Only three large British houses are represented in Brazil, and the agents for two of these, although thoroughly reliable people, are scarcely in a position to secure large orders in competition with the German and American makers. There is a tendency on the part of the small interior towns to establish, either directly or by concession, their own electric light and power plants, and a fair share of this business might be secured by a more active policy on the part of the British manufacturers, either by the establishment of local branches or by financial co-operation with local representatives lacking means, but otherwise well qualified to do the business.

CEYLON.—The Kandy Hotels, Ltd., are raising fresh capital for the purpose of electric lighting.

GLASGOW.—Tenders are invited by the sewage department for mains, switchboard, distribution boards, mains, cables, switches, &c., wiring and accessories for transmission of electrical power to motors, &c., and for lighting at the Shieldhall Outfall Works. Particulars from City Treasurer, Office of Public Works, 64 Cochrane Street. Deposit, £2 2s. Tenders by Oct. 4th.

HAYTI.—H.M. Consul-General at Port-au-Prince reports that, the former contract for the electric lighting of that town and of Cape Hayti having lapsed owing to non-execution, the formation has been authorised of a Haytian company, under the name of the Compagnie d'éclairage électrique des villes de Port-au-Prince et du Cap-Haitien, to undertake the electric lighting of the towns.

LEICESTER.—The Tramways Committee recommend that application be made to the Local Government Board to sanction a loan of £7,000 for cables and works in connection with the supply of electrical energy from the tramways generating station for power purposes, &c.

LONDON: *Battersea.*—£120 is to be spent in extending mains to Muncaster Road, Battersea Rise House Estate.

OULTON BROAD.—The Urban District Council invite applications from companies or individuals who will undertake the carrying out of their Electric Lighting Provisional Order.

SOUTHAMPTON.—The Local Government Board have sanctioned the borrowing of £2,500 for mains, and £700 for services.

SOUTHEND.—An application is to be made to the Local Government Board for sanction to borrow £13,715 for the erection of two sub-stations for the purpose of supplying current in the eastern and western portions of the borough.

WALTHAMSTOW.—The Electrical Engineer has been directed to prepare a specification and invite tenders for the supply of the necessary cable for inter-connecting the large feeder at Higham Hill with the Blackhorse Lane feeder. The Lighting Committee, having gone into the question of public lighting, have decided in favour of an application being made to the Local Government Board for sanction to borrow £9,036, the estimated cost of converting 921 gas lamps to electricity.

Miscellaneous

AUSTRALIA.—The Australian Postmaster-General is inviting tenders for the supply of ferro-concrete telegraph poles in order to ascertain whether there are any other poles on the market than the patent production of the Cubitt Concrete Construction Co., which has offered to supply him with poles at the rate of £50 5s. 6d. for 60 poles, each 30 ft. long. The Postmaster-General thinks similar poles might be made quite as cheaply in Australia.

METROPOLITAN RAILWAY CO.—The directors invite tenders for the supply of stores during the year ended October 31st, 1910, including the following:—Electric wires and cables, electric lamps, carbons, switches, fuses, telephones, cells, &c.; electrical insulating materials; signal and telegraph ironwork insulators, &c. Tenders to the Secretary, from whom particulars, by October 4th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—Rebuilding and extension of the Railway Passengers' Assurance Co.'s offices, 64 Cornhill. Architect, William Wallace, 27a Old Bond Street, W.

S.E.—New offices for the Sons of Temperance Friendly Society, Blackfriars Road. Builders, John Marsland & Sons, York Street, Walworth, S.E.

S.W.—Building, Stanley House, Farm Lane, Walham Green, Fulham S.W. Architect, C. W. Stephens, 49 Hans Road, S.W.

W.—Swedish Church, Harcourt Street. Architects, Niven & Wigglesworth, 104 High Holborn, W.C.

Shops, King Street, Hammersmith. Surveyors, Farebrother, Ellis & Co., 29 Fleet Street, E.C.

Flats, Portland Court. Architects, Boehmer & Gibbs, 11 Spring Gardens, S.W.

PROVINCES.

ABERYSTWYTH.—Pavilion, Castle Grounds. Borough Surveyor, Aberystwyth.

ASHTON-UNDER-LYNE.—Infirmary. Architect, Mr. Jenkinson, Ashton.

AYR.—Factory premises, York Street Lane, for Jas. Green, Woodfield Road, Ayr.

Business premises, Alloway Street, for Hourton & Sons (£6,000). Architect, Allan Stevenson, Cathcart Street, Ayr.

Digitized by Google

Starch factory, River Terrace, for Hyland & Co. (£1,100). Architect, J. K. Hunter, 51 Sandgate, Ayr.

BANGOR.—Hospital. Architects, Young & McKenzie, Scottish Buildings, Belfast.

BIRMINGHAM.—Office premises, Needless Alley. Architect, E. Harper, Corporation Street, Birmingham.

Additions to Workhouse (£700). Architect, W. H. Ward, Paradise Street, Birmingham.

BOURNEMOUTH (WINTON).—Schools (£13,930). F. W. Lacey, surveyor, Bournemouth T. C. Builders, J. & M. Partick, London.

BRISTOL.—Extensions, College. Builders, Cowlin & Son, Statton Street, Bristol.

COATBRIDGE.—Skating rink, Church Street. Architect, W. Apton, Clark Street, Airdrie, N.B.

DARTFORD.—Tenders are invited by October 13th for the wiring of the Council Chamber and offices. Particulars from the Clerk.

DUDLEY.—School, Holly Hall. Architect, T. Grazebrook, High Street, Stourbridge.

DUMFRIES.—Additions to Academy (£7,700). Architects, Crombie & McKenzie, Union Chambers, Dumfries.

New Free Church, George Street (£1,400). Architects, Barbour & Bowie, Dumfries.

DURHAM.—Hall, Wheatley Hill (£2,000). Architect, J. Garry, Church Street, West Hartlepool.

EXETER. University College (£15,000). Architects, Tait & Harvey. Builders, Westcott Auston & White, Exeter.

GATESHEAD.—Entertainment hall. Architect, H. Gibson, Camden Street, North Shields. Builder, W. T. Weir, Howden-on-Tyne.

HALIFAX.—Additions, Narwood Green Provided School (£2,000). Architect, J. V. Edwards, County Hall, Wakefield.

JARROW.—Entertainment hall. Architects, Kelvey & Penlington, St. Anne's.

KILLARNEY.—Extensions to Cathedral (£22,000). Architect, Mr. Ashlin, Dublin. Builders, Hearne & Son, Waterford.

LEEDS.—Bank, Park Lane (£7,000). Architects, Perkin & Bulmer, Leeds. Builders, Nicholson & Son, Leeds.

New works (£30,000). Leeds Fireclay Co., Ltd., Leeds.

ROCHDALE.—R.C. school (£4,000). Architect, O. Hill, Albert Square, Manchester. Builders, R. & T. Howarth, Rochdale.

ROTHERHAM.—Y.M.C.A. premises. Architect, J. Totty, Rotherham.

SOUTHEND-ON-SEA.—Church. Architect, B. Parker, Bank Chambers, Southend.

WALSALL.—St. Patrick's Presbytery (£2,110). Architect, H. S. Sandy, Greengate Street, Stafford.

TENDERS RECEIVED AND ACCEPTED

BURNLEY.—The tender of Messrs. Carter & Co. for electrical supplies has been accepted by the Board of Guardians.

BURY.—The Corporation have accepted the tender of Messrs. Ferranti, Ltd., for the switchboard gallery at the new Chamber Hall power station

G.P.O.—Messrs. Reavell & Co., Ltd., Ipswich, have received an order for a large electrically-driven compressor of the quadruplex double-ended type to the order of the General Post Office for pneumatic despatch at the Central Post Office. Each end of the machine has a device for automatically controlling the volume, and may be used for either vacuum or pressure.

HANLEY.—The tender of the Brush Electrical Engineering Co., Ltd., for a motor generator in connection with the new lift at the Town Hall, has been accepted at £144.

LEYTON.—In connection with a street lighting contract, 100 of Messrs. Venner & Co.'s time switches are included as a sub-contract.

LIVERPOOL.—The D. P. Battery Co., Ltd., have received an order for the renewal of the large batteries at Waterloo owned by the Liverpool District Lighting Co., and for their maintenance for a period of eight years.

LONDON: *Battersea.*—The Council have accepted the following tenders in connection with the wiring and fitting up of consumers' premises with arc lamps, and for the supply of goods in connection with the hire-purchase scheme:—The Beck Flame Lamp, Ltd., flame arc lamps; Brockie Pell Arc Lamp Co., enclosed arc lamps; British Westinghouse Electric Manufacturing Co., Ltd., motors (open type); G. A. Gunn and Phillips & Co., arc lamp installations; Stegmann & Co., Phillips & Co., and J. W. Gunn, motor installations.

ROTHERHAM.—Messrs. Reavell & Co., Ltd., Ipswich, have received an order from the Corporation for an electrically-driven compressor, for supplying air to the various pneumatic sewage ejectors in the borough. The machine has a large range of variation in speed, which is controlled by hand. It is also fitted with two special air relay devices, one set for the maximum pressure, and the other for the minimum pressure, which automatically operate a whistle when the pressure reaches either limit.

SOUTH AFRICA.—The Pretoria Town Council have accepted the tender of the Allgemeine Electricitäts Gesellschaft Co. for a generating set at £3,740.

SWANSEA.—With reference to our announcement of tenders accepted for street lighting by the Corporation, on page 823 of our issue for September 16th, we are asked to note that Messrs. Venner & Co. are sub-contractors to Messrs. Lucy & Co., for the time switches for controlling the lamps.

WEST HAM.—The Council have placed the following orders for coal for the electricity undertaking:—Messrs. E. Foster & Co., 5,000 tons Grangerigg Dry Peas for delivery between January and October next; Messrs. Cory & Son, 33,000 tons of coal at a price not made public; also 300 tons of Lynwood Rough Slack, 11s. 6d. per ton; Messrs. Speakman & Sons, 320 tons, Yorkshire coking smalls, 11s. per ton; 70 tons Yorkshire nuts, 11s. 6d. per ton; 400 tons Shafton Yorkshire Smalls, 10s. 4½d. per ton. The Council have also placed an order with the Armorduct Manufacturing Co. for certain sizes of cable to cover the estimated requirements up to March 31st next.

The tender of Messrs. Rowland & Hulton has been accepted for the installation of electric light at the Abbey School at £236. Sixteen tenders were received, ranging from the one accepted to £383.

MISCELLANEOUS CITY NOTES

CALCUTTA ELECTRIC SUPPLY CORPORATION.—An interim dividend of 6½ per cent. per annum on the ordinary shares for the half-year to June 30th has been declared.

LISBON ELECTRIC TRAMWAYS CO.—An interim dividend of 2½ per cent., free of tax, has been declared upon the ordinary shares.

MELBOURNE TRAMWAY & OMNIBUS CO.—A dividend of 4½ per cent. has been declared for the quarter ending Sept. 30th, equal to 15 per cent. per annum.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPORATION.—The full dividend on the six per cent. preference shares has been declared for the six months to September 30th.

BABCOCK & WILCOX.—An interim dividend of 8 per cent. per annum is announced on the ordinary shares, and of 3 per cent. on the preference shares for the past half-year.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO.—An interim dividend of 2s. 6d. per share, free of tax, has been declared for the quarter ended June 30th.

The Paris Tramway System.—The Paris tramways were originally horse-car lines, but have been gradually converted by the adoption of electric, steam, and compressed-air motors, and now only a few of the horse-car lines remain in service. The system as it existed at the close of 1904, the latest year for which complete statistics are available, is described in a recent American Consular report. At that time the system was practically in the hands of five large companies. These are as follows:—(1) Compagnie Générale Parisienne, with 14 lines (all electric); (2) Western Tramway Company, 5 lines; (3) Electric Tramway Company of the Left Bank of the River Seine, 2 lines; (4) Eastern Tramway Company, 15 lines; (5) Tramways of Paris and the Department of the Seine. This is an important group of lines, 36 in all, which radiate from the city to St. Denis, Aubervilliers, Courbevoie, and other towns and villages in the department. There is thus to the credit of the five companies 62 lines of tramways operated, over which 190,050,986 passengers are carried in an average year. Many of the cars are double-decked, the fare within the fortifications being generally 3d. for the inside and 1½d. for the upper deck. Certain routes are divided into sections of about two miles, for which 1d. per section, or 1½d. the whole distance, are the fares charged. The total mileage of all the tramways in Paris during the year 1904 was 12,348 miles, and the aggregate receipts were £1,066,700, an average of 1s. 5d. per car-mile. The cars in Paris stop only at regular stations fixed by the police. The concessions granted to the companies prescribe the minimum number of daily trips, the capacity of cars, the limitations of speed, the duration of the charter, and the price of the fares. All concessions for lines which pass beyond the fortifications are granted by the State. Some, but not all, of the electric tramway lines operating within the city limits use the overhead trolley system. On certain crowded streets the use of a surface conduit or conduit system was enforced. The companies are generally required by their charters to keep in repair that portion of the highway which lies between their tracks and about 2 ft. on the sides. The several lines vary in respect to the maximum distance to which a passenger is carried for one fare. Most lines run first- and second-class compartments or cars, and the fares are usually in the proportion of 3d. for first and 1½d. for second class. The tax or contribution the various tramway lines pay to the municipality is calculated to be about 4s. per car per day. The municipal budget of 1905 shows that the city received from public conveyances a revenue of £450,000; but this item includes cabs and omnibuses as well as street-car lines. The other taxes are not large, and are in the form of rental for the occupation of the streets. Thus the Company of Tramways of Paris and the Department of the Seine, with 36 separate lines and branches, paid only £400 during the year.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 7s. 6d. to £60 17s. 6d. per ton (last week, £60 5s. to £60 15s.).

ADNIL ELECTRIC CO.—Mr. J. B. Chambers has been appointed engineer and representative for the Yorkshire district of the Adnil Electric Co., Ltd. (late Marples, Leach & Co., Ltd.). Mr. Chambers has been connected with the engineering department of the firm for some years past, and would be pleased to advise on electric power and lighting installations, and quote on behalf of the firm for electrical plant in the district mentioned. His present address is 76 Hill Top Mount, Roundhay Road, Leeds.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Mr. A. Cupwell, 12 Cherry Street, Birmingham, has been appointed trustee in the bankruptcy of H. J. Burdett, electrical engineer and contractor, 16 Regent Street, Rugby.

A meeting of the General International Wireless Telegraph and Telephone Co., Ltd., will be held at 110 Cannon Street, London, on October 26th, at 11.30 a.m., to hear the liquidator's account of the winding up.

SOME B.T.-H. MOTOR CONTRACTS.—The following are among some recent orders secured by the power and mining department of the British Thomson-Houston Co., Ltd., of Rugby: The Braidwater Spinning Co., Ltd., 14 three-phase motors, main switchboard, &c.; Purex, Ltd., Greenford, 1 56-kw. generator; 1 20-kw. generator; 6 D.C. motors, starting gear, lighting material; Corlett Electrical Engineering Co. 5 D.C. motors and spares; the Carrongrove Paper Co., Ltd., 1 300-kw. D.C. generator, 3 three-phase motors, switchboard, and wiring, &c.; Bennett Bros., London, 27 D.C. motors and rheostats, 8 A.C. motors and rheostats; Williams, Harvey & Co., Ltd., Cornwall, 5 D.C. motors from 6- to 30-h.p., switchgear, &c.; Walter Somers & Co., Ltd., Birmingham, 3 30-h.p. D.C. motors, 3 15 h.p. D.C. motors and rheostats; Steel Peech & Tozer, 13 motors from 5 to 100 h.p.; Scott's Shipbuilding & Engineering Co., Ltd., Greenock, 8 D.C. motors from 10 to 120 h.p., with controlling and switchgear; Glasgow Corporation, Glasgow, 3 D.C. motors from 40 to 80 h.p. and switchgear; Powell Duffryn Steam Coal Co., Ltd., Aberdare, 10 three-phase motors from 5 to 30 h.p.; G. Whitehead & Co., Ltd., New Eltham, 2 three-phase 25- and 110-h.p. motors, switchgear, and wiring; Clarke, Chapman & Co., Ltd., 2 three-phase 100- and 200-h.p. motors and switchgear.

ROBERTSON PRIVATE FIRE BRIGADE.—The Robertson Electric Lamps, Ltd., Fire Brigade was successful in winning the championship of the United Kingdom, also the "Dewar" Challenge Shield, at the first part of the eleventh annual Tournament of the London Private Fire Brigades' Association on Saturday last. They also carried off first prize in the four-men drill, first prize in the five-men drill, and secured a substantial lead of 18 points towards the best aggregate for the "Marshall" Challenge Cup. The second part of the Tournament will take place some time in November.

CATALOGUES WANTED.—Messrs. Tyler & Freeman, of 20 New Bridge Street, London, E.C., desire all manufacturers of electrical and mechanical apparatus and machinery to send them complete copies of their catalogues, with prices and discounts, as they are arranging a new file.

Tramways and Telephones.—The September issue of the Tramways and Light Railways Association Official Circular, which has just been issued, contains the decision of the Arbitrator, Mr. G. L. MacFarlane, K.C., in the dispute as to whether the tramway authorities or the Post Office should bear the cost of inserting fuses and heat coils in Post Office telephone exchanges to protect the telephone apparatus in the event of telephone lines falling on trolley lines. The decision is against the tramway companies.

The Central.—We have just received a copy of the August number of the magazine of the Old Students' Association of the Central Technical College of the City and Guilds of London Institute. Articles appear on underground pipe-work and aluminium, and a description of a bridge in Canada. The usual notes on the doings of old students form a prominent feature, and views are given of some of the laboratories.

Walthamstow Telephone Exchange.—On September 11th the National Telephone Co. transferred the subscribers connected to its Walthamstow Exchange to a central battery equipment installed in new premises which have been specially designed in 3rd Avenue, Hoe Street, Walthamstow. The new equipment has been manufactured and installed by the Western Electric Co., of North Woolwich, and is of the No. 10 C.B. type, consisting of four subscribers' positions, giving accommodation for 480 lines, two incoming junction positions, and one electrophone and plugging-up position. The ultimate capacity of the switchboard is 1,600 lines, and the equipment is of similar design to that installed at the company's Crosby, Great Yarmouth, Greenock, and Rusholme Exchanges.

APPOINTMENTS AND PERSONAL NOTES

Mr. A. Aspinall, who has been connected with the Brighouse Corporation Electricity Undertaking for many years, has been appointed engineer and manager of the department.

Mr. T. C. Martin, who has been for some time co-editor of the *Electrical World* (New York) with Mr. W. D. Weaver, has resigned this position in order to take up the appointment as general secretary of the National Electric Light Association of America, with which body he has been connected since its foundation.

The Borough Electrical Engineer at West Ham reports that in addition to Mr. H. H. Holmes, sales manager, Mr. K. A. Boshell, chief clerk in the general office, and four members of the sales department staff, have resigned their posts to take up positions under the Marylebone Council. The principal vacancies so caused are to be filled up as follows:—Mr. Farndon, at present assistant sales manager, is to be appointed sales manager at £250 per annum, rising to £300; Mr. Edgerton, at present meter superintendent, is to be appointed assistant sales manager and meter superintendent at £200 per annum, rising to £250. The clerical staff of the general office and sales department is to be amalgamated and re-arranged.

Mr. Francis Teague, Borough Electrical Engineer at Bath, and Mrs. Teague celebrated their silver wedding last week, the occasion being taken advantage of by the electricity works staff and employees to present him with a silver tea service and salver.

Mr. S. E. Bastow, of Messrs. Bruce, Peebles & Co., Ltd., was entertained to dinner recently by a number of his friends in Edinburgh, preparatory to his leaving for a tour round the world on behalf of his firm. Mr. Bastow left by the *Tunisian* from Liverpool last week for Canada, and will proceed from there to Australia, New Zealand, and South Africa. He expects to be away for at least six months.

NEW COMPANIES

BOUDJAH ELECTRIC LIGHTING CO.—Registered on Sept. 14th, with a capital of £5,000 in £1 shares, to undertake the electric lighting of streets, public places, and private dwellings in Boudjah or elsewhere, to obtain concessions for electric lighting and electric power supply in the Turkish Empire. Registered office: 110 Cannon Street, E.C.

INTERNATIONAL FILAMENTS.—Registered on Sept. 11th, with a capital of £20,000 in £1 shares, to acquire from Sir John W. Ottley, C. F. Call, H. Reynolds, J. Metcalfe, W. Stewart, and M. Gregory, foreign and colonial rights and secret processes and inventions relating to the manufacture of metal filaments and electric incandescent lamps, and to carry on the business of electric, telegraph, telephone, mechanical and consulting engineers, manufacturers of and dealers in electric incandescent lamps and filaments, &c. Private company. First directors, W. Stewart and J. Metcalfe. Registered office, 34-6 Gresham Street, E.C.

CUNNINGTON & HARRIS.—Registered on Sept. 16th, with a capital of £5,000 in £1 shares (2,000 preferred), to adopt an agreement with S. Harris, and to carry on the business of electrical engineers, electricians, workers of and dealers in electricity, motive power, and light. Registered office, 21 North Audley Street, Grosvenor Square, London, W.

"Elementary Electrical Calculations." By T. O'Conor Sloane. (London: Crosby, Lockwood & Co.) 9s. net.

COMPANIES' MEETINGS AND REPORTS

WILLANS & ROBINSON.—The accounts for the half-year ended June 30th, show a loss of £3,501 on the half-year's working. Deducting this sum from the balance brought forward from last accounts, leaves £6,015 available for distribution. The directors recommend the payment of a dividend of 3 per cent. per annum on the preference shares, leaving a balance of £1,015 to be carried forward. There is no profit available for payment of interest on, or redemption of, funding certificates, and it is not possible to pay any dividend on the ordinary shares. The regrettable result shown for this half-year is due to the scarcity of work and to the low prices prevailing. The actual loss on the half-year's working at Rugby is £2,351. To this has to be added £1,170, the cost of keeping the Queen's Ferry Works in proper order and repair. The whole of the debenture interest is now charged against the Rugby account, and in considering the loss of £2,351 on that account it is pointed out that this result is arrived at after charging the Rugby profit and loss account with £4,824, the amount of the debenture interest for the half-year. The sum

Digitized by Google

shown in the profit and loss account as written off against depreciation of premises, plant, machinery, patents, &c., viz., £4,203, is considerably less than in past half-years. The deficiency, however, in this provision is apparent and not real. A number of the working costs of the business, such as drawings, patterns, tools, and other appliances, which in past half-years have been charged against capital account, and subsequently written off by depreciation, have in this half-year been charged direct against the profit and loss account. Although, therefore, the sum shown in the accounts as written off for depreciation this half-year is less than in the past, there are direct charges against profit and loss account to counterbalance this deficiency, and the actual provision made for keeping capital values on a sound basis is as ample as formerly. The full preference dividend for the half-year might have been made up by drawing on the reserve fund. The directors, however, in view of the continued depression in business, do not feel justified in recommending such a course. There is a considerable quantity of Diesel engine work in the shops at the present time; but the Diesel Company have so far been able to place only a small proportion of the orders due under their agreement. It is hoped that before long there will be a revival in the demand for electrical generating machinery, and the company is now in an excellent position for securing a good proportion of the business when the revival takes place. Meanwhile, every effort is being made to push new developments, such as turbo pumps, water turbines, and condensing plant, so as to widen the base of the company's operations, and make it less dependent on one class of manufacture. The first of the high-lift turbo pumps has successfully passed its trials, and there are a number of these and of the water turbines under construction in the shops. The directors do not for the present propose to make any addition to the board, nor to fill up the vacant post of chairman. The meeting is on October 5th.

WILLIAM GRIFFITHS & CO.—Meetings of the preference and ordinary shareholders were held on Tuesday to consider a scheme of reorganisation. The scheme, which was approved, provides for the formation of a new company with a capital of £157,000, divided into 275,000 shares of 10s. each, all of one class. Each preference shareholder in the present company will receive first mortgage debentures of the nominal amount of £2 10s. and five ordinary shares of 10s. each in respect of each £5 share. The ordinary shareholders will receive five shares of 10s. each in respect of each £5 of their present holding.

JOHNSON-LUNDELL ELECTRIC TRACTION CO.—The ordinary general meeting was held in London on Tuesday, but the proceedings were private.

DICK, KERR & CO.—The ordinary general meeting was held in London on Tuesday—Mr. John Kerr, chairman of the company, presiding. The report and accounts, given in abstract in our last issue, were adopted. He said that the past twelve months had been the worst for many years in respect of very severe home and foreign competition, and there had also been a serious diminution in the amount of work offered. He regretted that the directors could not hold out any bright hopes for the current year. They were gradually extending their connection in foreign markets, and hoped to be able to get better prices there when competition was less keen.

MUNICIPAL TRAMWAYS ASSOCIATION

THE eighth annual conference of the Municipal Tramways Association held in London last week under the presidency of Mr. A. L. C. Fell, chief officer of the London County Council tramways, commenced on the Wednesday with a reception by Sir Melvill Beachcroft, J.P., Chairman of the London County Council, at the County Hall, Spring Gardens, S.W. The present is the third occasion on which the Association has met in London, the previous years being 1902 and 1905 respectively. Next year the meeting will probably be at Bradford, as Mr. C. J. Spencer (General Manager of the Bradford Corporation Tramways) has been elected President in succession to Mr. Fell. Mr. James Dalrymple (General Manager of the Glasgow City Tramways), succeeds Mr. Spencer as Vice-President.

Sir Melvill Beachcroft opened the conference with a welcoming speech, after which Mr. A. L. C. Fell read his Presidential Address.

Presidential Address

AT the commencement of his Address, which was entitled "Tramway Problems in the Future," Mr. Fell gave a few statistics which, he said, indicated that the rush with regard to the construction of electric tramways was over, and that improved results were chiefly due to gradual development of existing systems and the reconstruction of horse, cable, and steam tramways. For some considerable time no new large schemes have been brought before Parliament.

Referring to suggestions that the time had arrived for the Tramway Act of 1870 to be revised, he emphasised the necessity for municipalities to settle their broad line of policy before Parliament was asked to take action.

Personally, he thought that the most unfair points in connection with this matter were:—(1) the local road authority can stipulate what paving is to be used; (2) competing forms of locomotion do not pay for the cost of installing or maintaining the paving; (3) the tramway authority has to pay rates on the earning capacity of its lines, whereas other competing forms of locomotion using the streets are not so rated.

Until some agreement is come to, he continued, between the tramway authority and the highways authority, it is no use attempting to apply to Parliament for an alteration in the Tramway Act with regard to these matters, but the sooner the agreement is made the better it will be for all municipalities. The popular fallacy had existed for some time that the installation of a tramway increases the congestion in the street, but the speaker proceeded to show that experience had demonstrated that under general conditions this was not the case. Also, a tramcar took up much less space in the street per passenger seat than any other type of public street vehicle at the present time.

It was to be regretted that more friendly relations did not exist between railway and tramway authorities, as much more benefit would accrue from friendly co-operation than from antagonistic competition. A tramway was, in his opinion, more suitable in every way for dealing with local short-distance riders, and he gave figures of the large tramway undertakings in this country to show that the majority of passengers travel a distance of considerably less than two miles. Under the heading of Railway Companies he did not include the London tube railways. Much might be done in connection with through booking between all railways and tramways, and he suggested that the Association might take the initiative and endeavour to arrange a conference with the representatives of some of the railway companies.

An attempt had been made during the past year to see if arrangements could be entered into for the Association to come in closer touch with the International Tramways Union, but owing to the fact that under the constitution of that Union of Associations the subscription is based on the capital outlay of the various undertakings represented, the subscription from this Association, under these regulations, would be out of all proportion to the benefits received.

Passing on to speak of rail-less trolley systems, he expressed the view that in certain special cases the system would have its uses. For instance, in London it might be advantageous as a connecting link between the tramways which run to either side of the Blackwall and Rotherhithe Tunnels under the Thames; in these cases a tramway could not be satisfactory, but in ordinary service he was afraid that the cost of maintenance of the rail-less system would be high.

It had been suggested that the rail-less system might be used for so-called "missionary work," to ascertain the best route for a tramway, but, in his opinion, it was a question as to whether this was really necessary. If people thought that the route was only an experimental one, they would not settle down and take houses on lease, but if a well-thought-out tramway were installed they had a feeling of security.

With regard to the reports of the special committees on brakes, it was to be regretted that a joint memorandum from the Special Committee of the two Associations had not been submitted to the Board of Trade, stating definitely how far the recommendations are in agreement. During the past few months the members of the Brakes Committee of the Association had endeavoured to do some preliminary work in this direction, and a further brief report was to be presented to the members during the conference. The Association was to be congratulated on the results of the further efforts made by the Income Tax Sub-committee. The Commissioners have gone a long way to meet the objections raised. It was suggested by Mr. Aldworth, in his Presidential Address last year, that the Municipal Tramways Association should be incorporated. All the necessary

Digitized by Google

preliminary work had now been done, and it was hoped that a definite decision will be arrived at during the present conference.

After a few words on the necessity for standardisation of equipment, Mr. Fell called attention to its desirability also in accounts and reports. As an instance, the well known unit "car mile" was most unsatisfactory as a comparable unit in view of the varying seating capacity of different cars. What we really want to know is the cost per passenger per mile, or per "seat mile."

Other points dealt with were through running and the use of trailer cars, in connection with the latter of which the use of double-decked trailers was suggested, and it was mentioned that the Board of Trade and the Police Authorities had recently agreed to trailers being run experimentally on one route in London.

The next section of the Address dealt with conditions of labour, and enlarged upon the difficulties with regard to what is known as spread-over time; this is the period covered from the time a man starts work in the morning until he completes his work in the evening, including the time when he is off duty during the middle of the day. In London there is a very high peak for a short time in the morning, and another high peak, which lasts somewhat longer, in the evening. Thus a large number of cars are run only for a short time in the morning and again in the evening, and it is most difficult to cut down the spread-over time of the employees working these cars. At the present moment about 40 per cent. of the cars are not required for service between 10 a.m. and 4 p.m. In many provincial undertakings, the load between 12 noon and 3 p.m. is augmented by large numbers of people going home to dinner. When these conditions exist, a very much greater percentage of all-day cars can be run, and it is possible, in the majority of cases, to arrange the hours of duty of the employees in two shifts of a reasonable length with one short period for relief. A possible solution appears to be the introduction of a heavy goods service, worked in conjunction with railway and dock undertakings. A service of this description would be very beneficial to the tramways undertaking, and to the employees, and would relieve the congested traffic in the main streets, and in many instances the necessity for street widenings would disappear. He then went into some of the details of the steps which have been taken to form Conciliation Boards in connection with the London County Council tramways undertaking.

Mr. Fell then made a few remarks upon the growing use of steel wheels, the adoption of which he urged against much criticism in a Paper in 1902, and pointed out that from replies received from 53 municipal tramway owning authorities, it appeared that about 93 per cent. of the wheels are steel-tyred and only 7 per cent. are chilled iron.

In his concluding words Mr. Fell said :—"I venture to think that twenty years hence tramways will predominate, and rare specimens of an extraordinary vehicle which was called a motor omnibus will be found in the South Kensington Museum. The question of local railway competition will be settled, and internal pick-up traffic will be recognised as legitimate tramway work, and all longer distance through traffic will be dealt with by the railway companies, the tramways acting as feeders for railway undertakings."

The Medical Examination of Tramway Employees.

A Paper on this subject was read by Councillor A. W. Chapman, M.B., C.M., Deputy Chairman of the Manchester Corporation Tramways Committee. His opinion was that all employees should be medically examined when engaged, and re-examined every five years. It was, he thought, necessary in the interests of the public safety, and also from the business point of view. The Brakes Committees of the Municipal Tramways and of the Tramways and Light Railways Associations had recommended medical examination as essential. Already about 21 undertakings had their drivers and guards examined by a medical man, and in eighteen other cases drivers were tested for sight and hearing. The examination should be similar to that for life insurance, with the addition of special tests for sight and hearing. An examination form now in use in Manchester, and the results of the examinations between June, 1908, and May, 1909, were appended to the Paper. The author recommended that the examination should be entrusted to a young consultant or specialist in preference to a general practitioner. In the course of his Paper he pointed out that cases already decided under the Workmen's Compensation Act had shown that existing disability of any employee did not remove the employer's liability under the Act, so that it was very necessary to prevent any men suffering under any disability from entering the service.

A spirited discussion followed the reading of this Paper. Mr. A. Nance (Belfast) opposed examination by a medical man on the ground of expense. The employees in Belfast were examined for sight and hearing by a tramways official, and he thought that was sufficient. Dr. Collie, the medical examiner for the London County Council Tramways, suggested that public safety should be considered before expense, and outlined the system adopted by the L.C.C. Of 2,703 drivers examined within the last few years, 217, or 8 per cent., had failed. Defective vision was the reason in 147 cases, of which 65 were colour-blindness. He recommended frequent re-examination, as in the case of railway drivers, and drew attention to the danger of a non-medical examiner passing a case of heart disease. Mr. R. A. Smithson (Leeds) referred to the examination in Leeds, which was done by a general practitioner at a charge of 3s. 6d. per man. Mr. J. Dalrymple (Glasgow) said that every man had been examined medically in Glasgow for the last seven years. Applicants were tested for sight and hearing by a tramways official, and passed on to the doctor if fit in these respects. He thought the Association should make medical examination compulsory.

The L.C.C. Tramways Repair Depot.

The second Paper to be read was that by Mr. W. E. Ireland (Rolling Stock Superintendent, L.C.C. Tramways), on the central repair depôt of the London County Council tramways at East Greenwich.

The shops already completed, the author states, cover 3·25 acres, and consist of smiths', machine, wheel, truck overhauling, inspection, body and paint shops, and tool, finished part and general stores on the ground floor, with electrical repair, plough, tool, light machine and pattern shops on the galleries. The present building, which has a capacity for dealing with the overhaul of 600 cars per annum, has been planned with a view to future extension without breaking up the continuity of the several shops, which are arranged on a definite scheme for dealing expeditiously with the cars during the two weeks each has to be in the shops for its annual overhaul and renovation. The work required on the trucks, motors, and bodies usually takes about four days to complete, at the end of which time the whole car is reassembled ready for the paint shop. The painting and varnishing occupies a week.

The smiths' shop contains eight 48 in. by 48 in. down-draught hearths, and six 36 in. by 24 in. of the pedestal type, two 5 cwt. motor-driven pneumatic power hammers, one 60 in. exhauster fan with a capacity of 22,000 cubic feet of air per minute at 3 in. to 4 in. water gauge, one 17½ in. blast fan with a capacity of 2,500 cubic feet of air per minute at 8 in. to 10 in. water-gauge pressure, and other items. Stoneware ducts 30 in. diameter are laid in the ground, and provided with branches brought to the floor level for connecting with the draft pipes of the hearths. These ducts terminate in a square brick chamber, into which the 60 in. exhauster is built. The blast pipe is also composed of stoneware ducts laid alongside the exhaust mains. The wheel shop is equipped with three high-speed tyre-turning lathes, three tyre-boring mills, one 150-ton power wheel press, one wheel-boring machine, one 4-hole gas tyre-heating hearth with jib crane and pneumatic hoist, and half a dozen jig saws for cutting off tyres. The tyre-turning lathes are capable of taking a cut 0·5 by 0·125 in. at 50 ft. per minute on high carbon steel tyres. Each is driven by a 36-h.p. polyphase motor direct coupled to a change speed gear, the maximum purchase of which is 712·5 to 1. It has not been found possible with these machines to get above 30 ft. per minute cutting speed on tyres of from 0·60 to 0·68 per cent. carbon, skin hardened by constant rolling on the track. Tests have shown that tools fail much sooner with a light cut on a machine which "chatters" than with a heavy cut on a rigid machine, and whereas in the earlier type of lathe from eight to ten hours were required to return a pair of tyres, or an average of six pairs per week of 54 hours, with the rigid machines now in use the average output of each machine is six pairs per day, or 34 pairs per week of 54 hours. The life of steel tyres made to the Council's specifications averages 56,000 miles for pony wheels and 50,000 for driving wheels; this gives an average rate of wear per ⅛ in. radial reduction of thickness of 5,090 miles and 4,545 miles respectively. At the present time some 430 new tyres and 575 pairs of wheels complete are handled in this shop per month, or an average of 5,160 and 6,900 respectively per year.

The machine shop is equipped with one 3-ton overhead three-motor crane running the full length of the shop. This operates at the following speeds :—Longitudinal travel, 200 ft. per min.; cross traverse, 100 ft. per min.; hoist, 30 ft. per min. Besides some 25 machine tools of various types, there is an oil- and waste-saving plant in this shop for dealing with the wool waste from axle boxes and bearings, in addition to the ordinary cotton waste and wipers. Both waste and oil are reclaimed. The plant is designed to handle about 20,000 lbs. of wool waste and reclaim some 12,000 gallons of oil per year, and it is estimated that the saving will be in the neighbourhood of £600 to £700

NOTICE

On and after the 1st October, 1909, the GENERAL ELECTRIC CO., LTD., will be able to deliver promptly

200-260 v. 32 WATT

22·5 British C.P. = 25 Hefner C.P.

OSRAM Lamps.

These Lamps are in every way as efficient as the 40 and 63 Watt Single Burning High Voltage Lamps which have achieved such a notable success—and will burn at any Angle.

SOUND DELIVERY GUARANTEED ON CONSIGNMENTS OF 25 LAMPS AND UPWARDS.

PRICE 4/3 EACH.

IT IS RECOMMENDED THAT ORDERS BE PLACED AT ONCE.

The General Electric Co., Ltd.,

HEAD OFFICE:

71, Queen Victoria Street, LONDON, E.C.

per annum. The line shafting in this shop is driven by five 36-h.p. polyphase motors attached to the upright stanchions. The shafting is divided into five sections coupled by means of claw couplings.

The tool and finished part shop and general stores are located between the machine and truck overhauling shops. The general store contains a 20-ton weighbridge and some 7,000 steel bins. The truck shop is equipped with two 5-ton three-motor cranes and the usual fitters' benches, vices, pneumatic drills, hammers, chippers, &c. There are 14 working tracks, each capable of accommodating four bogie trucks or three single four-wheeled trucks. A narrow-gauge track runs along the full length of the shop on the side adjacent to the stores, with branch lines between alternate pairs of truck tracks, and two small battery power motor-driven service wagons are in course of construction. Case-hardened steel pinions are now standardised, the increased life obtained more than compensating for the slightly increased cost. They were first tried in 1906. The pinions then fitted are still in service, and the average mileage of the 32 pinions fitted is to date slightly over 110,000 miles each, whereas the average life of unhardened pinions working under exactly similar conditions is from 19,000 to 20,000 miles each. The life of ordinary cast-steel gear wheels meshing with the case-hardened pinions is also improved. It has been found that the steel which gives the best results from all points of view has the following analysis :—Carbon, 0·15 per cent. ; silicon, 0·02 per cent. ; sulphur and phosphorus, not to exceed 0·05 per cent. each. The pinions are specified to be case-hardened to a depth of not less than $\frac{1}{16}$ in. from the surface of the teeth, the centre being left soft. The lubricating mixture, which has been in use for some four years, is composed of black axle oil and sawdust mixed in the proportion of 42 gallons of oil to 216 lbs. of sawdust, the cost of which works out at approximately 4s. 8½d. per cwt.

A traverser pit, continues the author, occupies a central position in, and extends the full length of, the building. B.S.S. No. 4 C track rails are laid at 13 ft. 6 in. gauge with standard L.C.C. conduit work in the centre. Power is supplied to the traverser motor from the conduit conductors by means of a standard car plough. The inspection shop contains 15 tracks with pits, and gangways between them, 1 ft. 1¾ in. below the rail level. The shop is equipped with hydraulic pit jacks, and a system of compressed air pipes with cocks at frequent intervals for connecting to pneumatic drills and other portable tools. The painting shop has eight tracks, each capable of accommodating three cars. Motor-operated roller shutters separate this shop from the traverser pit. Between each pair of tracks H-section columns are fixed, provided with movable wrought-iron brackets for supporting planks on which the painters stand. The shop is steam-heated, and maintained at a temperature of 60° F. On one gallery are a patternmakers' shop, tool shop, and a number of light machines operated by a 20-h.p. motor. A large gallery above the traverser pit is served by a 3-ton three-motor travelling crane, with a longitudinal travelling speed of 350 ft. per min. One end of this gallery is occupied by the test room. Here all repaired armatures are placed in testing frames and run on load in both directions, the artificial load being absorbed by a Froude water dynamometer. Brake magnet and field coils also are tested here, before being replaced on the cars after overhaul. For testing field and brake magnet coils for internal short circuits, a frame of transformer iron with a hinged yoke across the top is used. The yoke is counterbalanced and made to lift clear of the front limb of the frame. The back limb carries a coil which is excited, and forms the primary coil of the transformer. The coil to be tested is placed on the front limb, and the hinged yoke dropped into position. If the coil under test has no short-circuit the current flowing in the primary circuit will be so small as to be scarcely readable on the ammeter; if, however, there is a short circuit in the coil, even if but one turn, an appreciable current will flow. Two commutator turning and grinding lathes, two armature banding lathes, and six coil winding machines, are also installed. The armature banding lathes are provided with a special saddle carrying the wire drums and an arrangement for tensioning the wire, by means of which valuable floor space is saved.

There are two types of plough in use; one is constructed with a solid hard rubber base, and the other is made with a built-up wood base. In the latest type of rubber base plough, the collector shoes are of cast iron, and fastened to a spring by a wedge. These shoes have an average life of 8,000 miles, and cost about 3¼d. per pair. The steel friction plates, which rub against the slot rail, have an average life of 3,000 miles, and cost about 9s. per 100. The total maintenance cost of ploughs, including all renewals during the last financial year, was 0·05d. per car mile. A new rubber base plough costs about 107s.

After describing the system adopted for keeping the rolling stock records and works labour costs, the author concluded with a few notes on the lighting and power supply. The depôt is lighted by 60 Davy "Sunrae" flame arc lamps, arranged in series of 10 on the 500 volt D.C. supply. The power supply is by three-phase H.T. 6,600 volt current direct from the generating station at Greenwich to a transformer room situated outside the depôt, and containing four 150 kw. single-phase Berry 6,600v/220v transformers. The feeders from the panels are laid in underground ducts to various sections of the depôt, where they are connected to fuse distribution boxes, from which each motor circuit is taken.

On Thursday morning the discussion on the above Paper was opened by Mr. H. E. Yerbury (Chief Engineer, Sheffield Corporation Tramways), who referred to the low speed of 30 ft. per minute obtained with the tyre-turning lathe. With a 3-16 in. cut and 1-16 in. feed, a speed of from 50 to 60 ft. per minute should be attained. Mr. C. J. Spencer (General Manager and Engineer, Bradford Corporation Tramways) said that the coil-tester described was also in use at Bradford. For testing coils *in situ*, a low frequency alternating-current was sent through four or eight coils in series, and a reduction in the choking effect gave an indication of short-circuits. Mr. E. S. Rayner (Manager and Engineer, Doncaster Corporation Tramways) asked whether the case-hardening of the pinions was done in the repair shops or by an outside firm. In reply, Mr. Ireland said that it had not been found possible to go beyond 30 ft. for minute on the tyre-cutting lathe even with the best Sheffield steel. The coil-tester described was also used in America; it cost from £6 to £8. All pinions were case-hardened by an outside firm who specialised in that work.

Comparison of Continental and British Tramways.

A Paper embodying some comparisons of Continental and British methods of operating tramways was read on Thursday by Mr. A. R. Fearnley, General Manager, Sheffield Corporation Tramways. He gave the chief differences to be met with on the Continent as follows :—(1) The adherence to the single-deck car; (2) The carrying of standing passengers, especially on platforms; (3) The universal use of trailer cars; (4) The increasing use of vestibule cars; (5) The adoption of the bow collector; (6) The provision of shelters; and (7) The development of ultra-suburban traffic by the railless traction system. With regard to the type of car, it seemed that the double-deck car had not had a fair trial on the Continent. The most serious objection the author had heard advanced was the continued and lengthy absence of the attendant from the platform. In working expenses the single-deck car showed very little saving over the double-deck car.

In Sheffield, continued the author, where, owing to severe gradients and railway bridges, 57 single-deck cars were being worked along with double-deck cars, the average current consumption per car mile by the latter on the most hilly route was 1·64 units per car mile, and on the most hilly single-deck car route 1·46 units per car mile, a difference in favour of the single-deck cars of only 0·18 unit per car mile. The seating capacity of the cars compared are : double-deck, 52, and single-deck, 28 passengers. The mileage obtained from tyres and brake-shoes on the two types was practically the same, and the traffic wages were the same.

Other important arguments in favour of the double-deck car were smaller quantity of rolling stock required; less car-shed accommodation necessary; and the accommodation afforded for smokers. In general the double-deck car suited the requirements in this country very much better than the combined single-deck car and trailer would do, and at considerably less working cost. With further reference to trailers, the author thought that there would be no objection to the coupling of trailers to double-deck open-top or covered cars, providing the bye-law regarding the entering and leaving of cars when in motion were rigidly enforced.

Continuing, Mr. Fearnley said that the use of the vestibule type of car was rapidly on the increase on Continental tramway systems, and he believed that their adoption in this country would increase, as the condition of the men working this class of car in the winter months, compared with those working the open platform cars, was very marked. With regard to the relative advantages of the bow collector and the trolley boom, he was of the opinion that the former was the better arrangement. The trolley boom, with its attendant overhead fittings, was, he thought, the most unmechanical feature of tramway equipment, and despite all that could be done in the way of perfecting overhead work, many serious accidents were only narrowly averted. The bow collector seemed to give entire freedom from danger in this respect. It further very considerably simplified the overhead fittings and construction work, although on the other hand it might shorten the life of the trolley wire. The author favoured the erection of

Digitized by Google

waiting-rooms and shelters, as used considerably on the Continent, and these could be built at a cost of not more than £30 to £40.

Turning to the new railless trolley cars, Mr. Fearnley expressed the opinion that if they were given a fair trial without unnecessary restrictions, they would within the next few years form an important addition to the tramway business. In this connection, the author gave some details of the hub motors used on the railless cars of the Vienna Municipal Tramway system. This motor gives about 20 h.p. at 190 r.p.m., and is designed with a stationary 10-pole field system fixed on the axle. The armature forms part of the wheel, and revolves round the fixed field system, being carried on ball bearings. The field poles are wound with flat copper strip of uniform section, but of varying width and depth, so as to utilise the space between the poles to the best advantage. A radial commutator with carbon brushes is used. Generally two motors placed in the back wheels are employed, but on heavy gradient lines motors are put in all the four wheels. In the author's opinion many suburban districts which are to-day without any connection with the existing tramway systems, and in some cases without any convenient means of access to the adjacent cities, will be able to be linked up by this means at a low capital cost, and yet obtain a satisfactory service. Such a system would be found sufficient for many years to come, and the laying down of track, with the consequent heavy capital expenditure, might be delayed for a considerable period. As yet no Corporation had obtained the necessary powers to work such a system, but it was anticipated that at least two of our large cities (Leeds and Sheffield) would obtain these powers within the next twelve months.

Another difference frequently met with on the Continent, continued the author, was the placing of the tramway tracks at the side of footwalks. This method did not appear to lead to any increase in accidents, and was certainly a very great convenience in the loading and unloading of cars. With regard to permanent-way construction, the author was of the opinion that in few places on the Continent was it equal to the permanent way to be seen on the majority of British municipal tramway systems. The junctions, crossings, and paving near the rails were certainly not kept in as good a condition as in this country. Grooved trolley wire was very largely used, and no doubt it had been found of equal advantage with the bow collector as with the trolley boom. Generally speaking, concluded the author, the Continental methods and system appeared to meet the requirements of, and to give satisfaction to, the passengers.

The discussion on this Paper was opened by Mr. F. Ayton (Chief Engineer and Manager, Corporation Electric Supply and Tramways, Ipswich), who thought that the wear on the trolley wire with a bow collector was less than with a trolley wheel, especially at the ears. A smoother passage with an absence of hammering, resulting in fewer breakages at the ears, was effected by the bow collector. Further, no time was lost at the terminus in changing over the trolley pole. Alderman Smith (Liverpool) said that, after trying both single- and double-deck cars in Liverpool, they had come to the conclusion that the latter were the best. When trailers were used with single-deck cars, there were more accidents to passengers alighting from the front car. They had not found that the passengers took longer to alight from a double-deck car. Mr. H. Mozley (Manager, Corporation Tramways, Burnley) hoped that the Association would not encourage the adoption of trailer cars; the large bogie car was the proper unit. He recommended the vestibule car, as it afforded protection to the driver. Reflection in the glass before the driver could be entirely prevented by hanging curtains behind him. He had found the reverse staircase very satisfactory. Referring to the provision of shelters, Mr. A. Blaylock (Birkenhead) thought that one reason for the scarcity of shelters in this country was the difficulty of obtaining sites; there was not space in the middle of the road. He had found the cost to be from £60 to £80 per shelter. Mr. J. B. Hamilton (General Manager, Leeds City Tramways) suggested that the reason why single-deck cars remained so popular on the Continent was merely that the people were accustomed to them. Trailer cars could be worked with safety if the people were educated to them. He expected to see a considerable development of the railless trolley system in this country. He hoped the Board of Trade would advise the Parliamentary Committees to give the tramway undertakings a free hand in this matter, and to prevent undue restrictions by local authorities. With regard to the enforcement of the bye-law respecting alighting and entering running cars, Mr. C. J. Spencer (General Manager and Engineer, Bradford Corporation Tramways) thought that if the cars stopped for every passenger, a decrease of 25 per cent. in the average speed would result. Bailie McFarlane (Glasgow) advocated the adoption of covered-top double-deck cars, on the ground of greater comfort in wet weather. In Glasgow there was no need for shelters, as the cars ran so frequently; they might be of use on the outskirts of the city, however. He thought that tramway undertakings should be assessed on the earnings, and not on the mileage of track, and hoped that there would be no rates to pay on a railless trolley route. Mr. S. C. Neumann (Bradford) spoke at some length on traffic problems, and Mr. P. Fisher (General Manager, Dundee Corporation Tramways) mentioned that, of the six shelters erected in that city, four had cost from between £150 and £350. There was an attendant in each, but, instead of being paid, he was allowed to carry on a business in newspapers, &c. In reply, Mr. Fearnley agreed with Mr. Ayton that there were fewer breakages of the trolley wire when a bow was used, but, on the other hand, he had, he said, proof of excessive wear on the trolley wire in Budapest, where the bow was used. The vestibule car was appreciated by the drivers in wet weather. He did not think that it would be such a waste of time to stop for all passengers.

A correspondent has suggested that probably one of the ma[illegible] reasons why Continental tramways adhere to single-deck c[illegible] and trailers is climatic. Over nearly the whole Continent [illegible] shine is more prevalent and much fiercer than with us. [illegible] covered top-decker would be too much like a glasshouse unless double roofed and provided with sun-blinds. A more technical reason is the prevalence of narrow-gauge lines, mostly of one metre, at Lisbon only 90 cm. The narrow gauge and the rougher tracks are against top heaviness. Trailers are the natural consequences of single-deck cars, and are, in many cases, a more economical provision for rush traffic than double decks. In some towns, too, trailers are used as workmen's cars, lower fares being charged than in the motor-cars. The use of open-sided cars for summer and closed-in cars for winter is also a climatic necessity in many Continental towns, and is obviously much more readily met by single-deck than by double-deck cars.

Current Consumption.

In a Paper by Mr. R. S. Pilcher, General Manager, Corporation Tramways, Aberdeen, which was taken as read, the author emphasised the importance of reducing the current consumption on tramway systems. In Aberdeen, the power costs were 23 per cent. of the working expenses, and in many towns in the country they were over 30 per cent. Most systems have now been running over five years, and have replaced pinions and started to replace gears and field coils, and, in the author's opinion, the only means of arresting the increase in current consumption, or of effecting any decrease, is to instruct the motormen in the correct method of driving. This was started in Aberdeen three years ago, and has been very successful. Each motorman is thoroughly instructed in the series-parallel system of control by means of diagrams, and shown how to use the momentum of his car to the best advantage. He is also instructed to maintain speed off the series position, and not to run on parallel, unless there is clear space ahead to get the full benefit of the extra consumption. Printed instruction papers, showing where a driver should be running in parallel, where in series, also where he should be coasting, are distributed, and all drivers are kept to their respective routes. An inspector, also, is put on the road to see that these instructions are carried out. Previous to this system being introduced into Aberdeen, the rise in current consumption each year, due to the ageing of track and car equipments and the extended use of top-covered cars, had varied between 6 and 12 per cent. per car mile. In the first year under the system, a reduction of 6 per cent. on the previous year was effected, or a saving of £640. Since then, namely, for three years, the same consumption per car mile has been maintained, and as the number of top-covered cars has been increased at the rate of six each year, this is equivalent to a gradual reduction.

All the service cars in Aberdeen are now fitted with ampere-hour meters, and the consumption is lower at present with 41 top-covered cars than it has been for the last five years, although there were only three top-covered cars in use five years ago. The meters have already paid for themselves by the reductions made. The motormen like the cars with the meters on, and become interested in the readings. Further, although several thousands of pounds have been saved in three years in Aberdeen, there has never been a single motorman suspended in connection with this subject. It has been found that the cars which run the slowest use the least current, even on routes with steep gradients, while on other routes where there is hardly any gradient the consumption is high, because of the high speed and the greater number of stops. After several dry days, when there is a great deal of dust accumulated about the rails, the current consumption rises, and a special sprinkling car, fitted with rail nozzles, is sent out to clean the rails. In concluding, the author referred to the fact that, simultaneously with the introduction of systematic supervision of the drivers, an improvement in the time-keeping of cars and a reduction in motor troubles were noticed, the car repairs for last year standing at 0·41d. per car mile.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The electrical equipment of Messrs. Yarrow's works at Scotstoun, on the Clyde, is dealt with in an illustrated article. Particular interest attaches to the large use of bare conductors in the works, the arrangement of which is described in detail. (Page 871.)

Under Electrometallurgy and Electrochemistry are given some notes on the manufacture of carbon electrodes for electric furnaces, chiefly from a report by Dr. E. Haanel.—The Rhodesia Broken Hill Development Co. are about to erect an experimental electrolytic reduction plant.—The establishment of an electric furnace plant for treating scrap iron jointly by the Transvaal Government and the Central South African Railways is under consideration. (Page 874.)

An improved method of disconnecting and removing the ploughs is employed on the cars of the Aldgate and Bow section of the London County Council tramways for the change over from the conduit to the overhead trolley section. A pair of spring contact rails are provided, so that uncoupling of the flexible leads is dispensed with. It is possible to cast off the plough without stopping the car. (Page 874.)

A note with regard to water-power stations for the generation of electrical energy in this country appears on page 876.

The announcement was made in the House of Commons last week that the Government have concluded arrangements for purchasing the Marconi land stations, with the exception of Poldhu and Clifden, for £15,000. It is stated that the United States Government have placed an order for a wireless station having a range of 3,000 miles. The Indian Government contemplate the erection of inland wireless stations. (Page 876.)

Particulars are given as to the arrangements which the Welsbach Incandescent Gas Light Co., Ltd., have made for replacing consumers' carbon lamps with metal filament lamps. (Page 877.)

A new telephone transmitter is described, invented by Messrs. C. E. Egner and J. G. Holmström, who recently made some successful experiments between Stockholm and Paris. As compared with the present usual forms of microphone, the alteration is a mechanical one to ensure parallel motion of the front dise

Digitized by Google

of the microphone at the maximum amplitude. (Page 877.)

A new and simple design of automatic switch for controlling the auto-transformers of small low-voltage lighting installations is described. (Page 877.)

Professor J. A. Fleming, F.R.S., delivered an introductory lecture on the opening of University College Engineering Department for the session, in which he dealt with several aspects of the question of training of electrical engineers. (Page 877).

A specification for ammeters and voltmeters has been issued by the Engineering Standards Committee. (Page 879.)

A system of charging a fixed sum per lamp per annum has been referred to a sub-committee of the Beckenham Council.—Bournemouth Corporation Tramways show a loss of £5,416 on the past year's working. The Council still refuse to run the cars on Sundays.—The L.B. & S.C. Railway Co. propose to increase the continuous demand for their Brighton workshops from 500 kw. to 600 kw.—The Dover tramway manager is to inspect the S.P. surface-contact system.—Folkestone Corporation are said to have approved of the S.P. surface-contact system.—The municipal electrolytic plant at Poplar for the manufacture of disinfectant is to be duplicated.—Islington and Paddington Councils have refused their consent to certain proposed tramways in their districts.—A special investigation is to be made into the working of the Newport (Mon.) electricity undertaking.—The L.G.B. refuse to sanction a loan for street lighting at Finchley, failing the receipt of a comparative estimate of the cost of gas lighting. (Page 879.)

Keighley Corporation require motor-generator, mains, switchboard, &c.; mains are required at Worthing; Diesel engine, &c., at Bray; and cables at Handsworth. Loans have been, or will be, applied for as follows:—Bridlington, £3,000; Longton, £1,740; Mansfield, £3,500; Kendal, £10,000. (Page 880.)

At the meeting of Messrs. Willans and Robinson on Tuesday, it was stated that for the present, and for the immediate future, a slack time was to be contemplated. A power supply company, advised by Mr. H. F. Parshall, is being organised in North-East Spain. (Page 882.)

J. W. B. writes pointing out the necessity of supply authorities watching installations wired on the concentric system with bare outer and double-wound transformers to see that extensions are not made with the bare outer and connected directly to the mains. He also refers in the same connection to the electric geyser recently described in our columns, in which the water actually carries the current.—The Welsbach Incandescent Gas Light Co., Ltd., have sent us a communication with regard to their metal filament lamps.—The Lord Mayor appeals for contributions to the National Institution of Apprenticeship. (Page 883.)

The following books are reviewed in this issue:—"The Theory of Electric Cables and Networks," by Alexander Russell; "Practical Alternating Currents and Alternating-Current Testing," by C. F. Smith; "Metric Tables," by Sir Guildford L. Molesworth; "English Prices and German Equivalents," by St. Koczorowski; and "Electrical Circuits and Diagrams," by N. H. Schneider. (Page 883.)

A serious gas explosion occurred last week in the mains conduits at Derby. (Page 884.)

Two Papers of electrical interest were read during the first day's proceedings of the meeting of the Iron and Steel Institute, which was held last week in London. In one of them Mr. Ljunberg described an electric furnace for the production of pig iron. Another Paper, by Mr. Ablett, dealt with steam and electrically-driven rolling mills, especially as regards measurements of power consumption. (Page 885.)

A suspender for heavy insulated cables and a new pattern of intermediate switch are described and illustrated on page 887.

We are able to publish results of tests of some large producer-gas engines in Hong-Kong. (Page 887.)

Among the specifications published by the Patent Office on Thursday last was one by G. H. Brown for improvements in an automatic block signalling system for railways; means of intercommunication between drivers and the signalmen in the cabins are also covered. A specification by C. O. Bastian relates to the quartz heater recently described in these columns, and Siemens Bros. & Co. and J. S. Huddleston have one for a clamping device for embodying in wiring fittings used in the earthed outer concentric system. J. von Zweigbergk protects a device for bringing the blow-out coil of a circuit-breaker into circuit only at the instant the arc is formed. C. H. Beaver and E. A. Claremont have patented a method of protecting overhead stranded and braided cables from the atmosphere. Opposition has been entered to the grant of a patent to S. Falk relating to a lamp-shade gallery. (Page 888.)

ELECTRICAL WORK IN MINES

In view of the increasing interest that is being taken in electrical work in collieries and in mines generally, we have decided to publish a monthly supplement to Electrical Engineering devoted to this subject. This supplement will appear on the first Thursday of every month; it will be inserted in the ordinary issue of Electrical Engineering, and will be supplied without extra charge. It is our intention to include in these supplements descriptions of actual plants and articles written by practical men in charge of electrical plant in mines. The first of these supplements will appear in our issue of Nov. 4th. A number of articles are already in preparation, and we invite further contributions from men who have experience in the erection of such plants or are in charge of them. Liberal payment will be made for accepted articles.

Telegraph Traffic.—Although the magnetic storm of last Saturday week has not caused any actual interruption of submarine cables, it appears to have opened out weaknesses in some, if not to have actually caused faults.—On the 28th ult. direct communication between Rome and Constantinople was interrupted, but a quick restoration was effected on the following day.—On the 1st inst. an Eastern cable was *hors de combat*, communication between Hong-Kong and Macao being thereby out of working order.—The cable steamer *Minia*, belonging to the Anglo-American Telegraph Co., was lying off Start Point near the Bolt Head wireless station on the 1st inst. repairing her engines.—On the 2nd inst. the Abyssinian line between Adua and Macalle ceased working, and several days will probably elapse before a restoration is effected.—News is still awaited of repairs to the cables between Tourane and Amoy; Cheikh Said-Perim, Assab-Perim, and Dakar-Conakry, while the land lines between Bachkale-Deliman, Teheran-Recht, and Bagdad and Bassorah have also to be put in working order.—A new cable has been laid by the Persian Government, presumably between Benderabbas and the Island of Henjam just opposite the town.—The Western Telegraph Co. will immediately begin laying the new cable uniting Argentina directly with Europe *via* Ascension. According to the *Financial Times*, the cable will cost about £1,000,000, and, it is hoped, will be in working order by Oct., 1910.—The Commercial Cable Co. has exchanged letters with the St. John's, Newfoundland, Municipal Council in respect to the laying of land cables. Permission has been granted to the company under certain conditions to do so, but it apparently does not see its way to accept them, the reasons being that the company is to be liable for any future tax or assessment upon corporations doing business in the city, and also to be subject to any regulations which the City may deem best to make, as well as to pay a tax of $2,000 a year to the city. According to latest advices, the company is seeking the intervention of the United States Government.—The Commercial Cable Co. proposes to divert another of its Transatlantic cables into St. Johns.—The German Postal Authorities have announced that unless marked otherwise, all telegrams to the Canary Islands, Senegal, Nigeria, and Mauritius will be sent *via* Emden over the new Borkum-Teneriffe cable.

THE ELECTRICAL EQUIPMENT OF YARROW'S SHIPBUILDING WORKS

ON the removal of Messrs. Yarrow's works from Poplar (London) to Scotstoun, on the Clyde, near Glasgow, a different problem was presented from that which has usually to be met either in equipping an old works with electric driving, or in laying out an entirely new works. On the one hand, the same machine tools were largely used, and these were already motor-driven at the old works, so that, as far as the actual application of the motors to the machines is concerned, there was very little new to work out, and practically no novelties have been introduced. On the other hand, as the old works had been electrically driven, valuable information was available as to the power required by the various machines and shops, and it was possible to design the distributing system with the maximum degree of economy. In this direction the use of bare cable in the shops is a particularly interesting point.

Current is supplied at 11,000 volts, 25 cycles, three-phase, from the Clyde Valley Electric Power Co., and both A.C. and D.C. are employed on the low-pressure side. Two 250-kw. British Westinghouse motor-generators (one of them spare) supply current for the D.C. motors, which are those removed from the Poplar works; the voltage of these is 210. They receive current from the L.T. side of three 200-kw. transformers, which also supply current for the remaining machines in the works and for lighting. One spare transformer has been provided. The voltage between phases is 400, and the lighting circuits are connected between the phases and a fourth neutral wire, so that the lighting voltage is 230. We understand that the lighting is quite satisfactory, in spite of the low frequency of 25 cycles; "Excello" flame arc lamps and "Meridian" enclosed arc lamps are largely used.

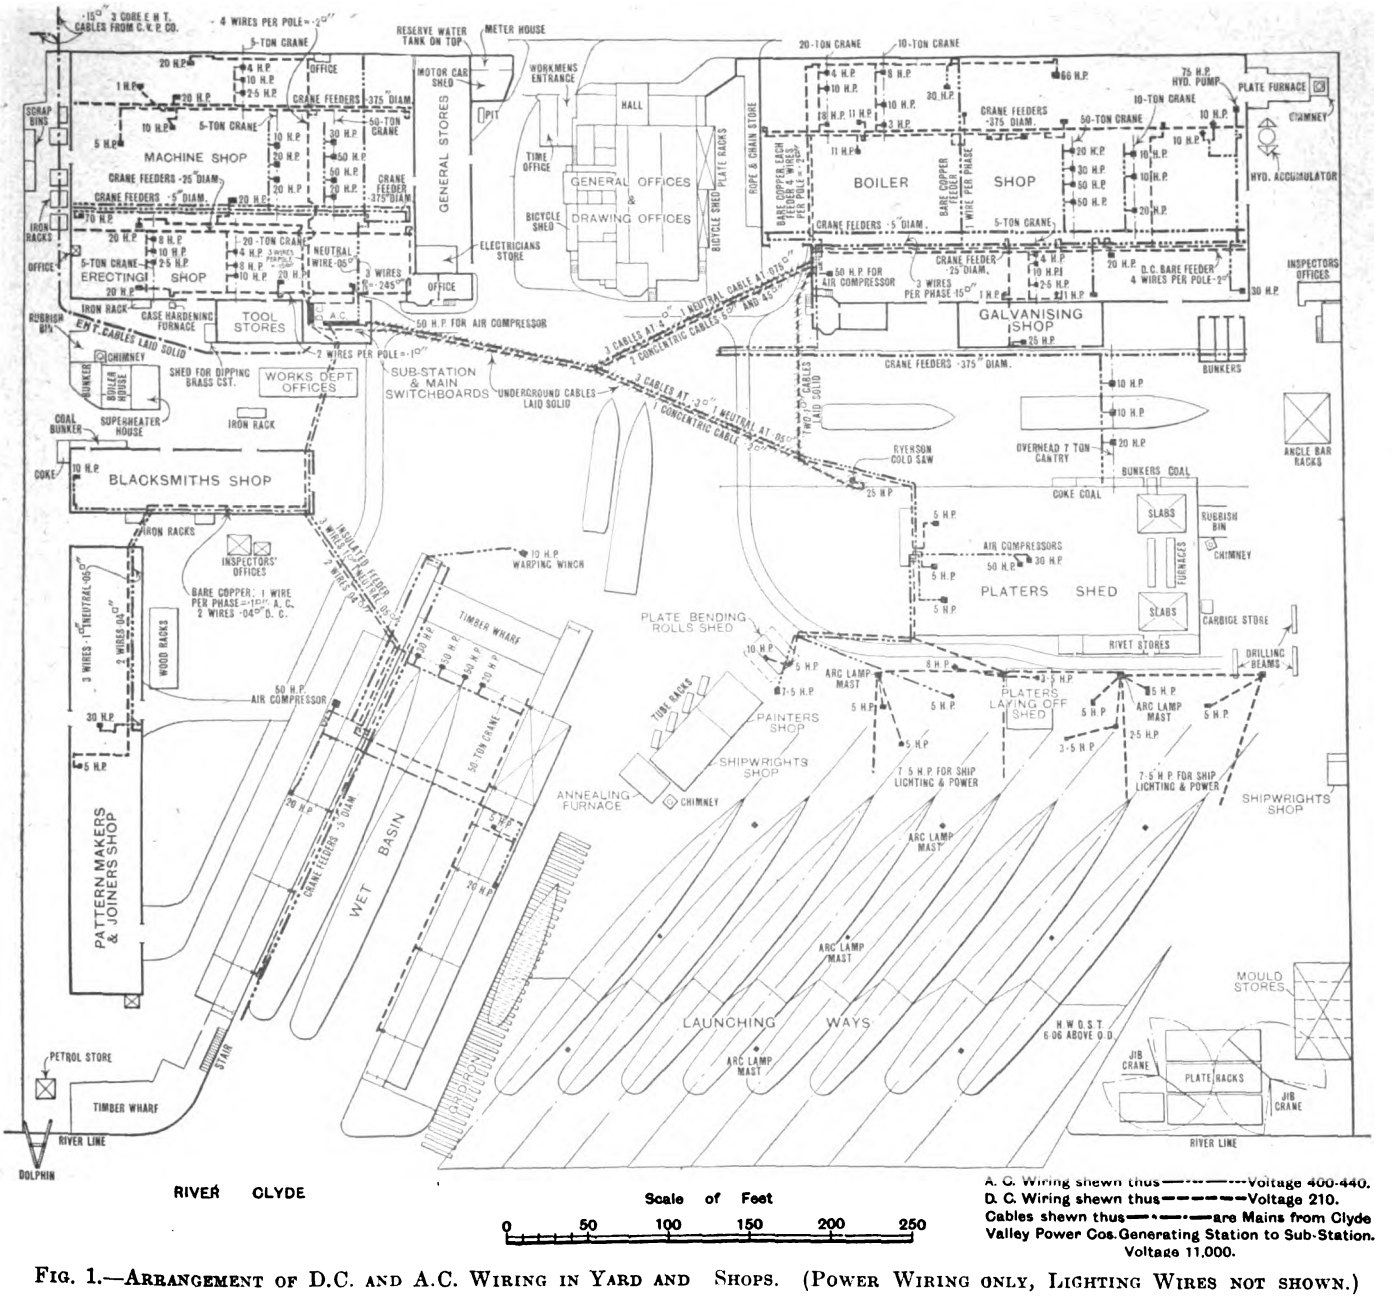

FIG. 1.—ARRANGEMENT OF D.C. AND A.C. WIRING IN YARD AND SHOPS. (POWER WIRING ONLY, LIGHTING WIRES NOT SHOWN.)

Two E.H.T. three-core cables supply the current from the Clyde Valley Co., coming from different sides of a ring main, so that, in the event of one breaking down, the supply is not interrupted.

Fig. 1 shows the general arrangement of the wiring. As is seen, the sub-station and main switchboards are at one corner of the machine and erecting shops. There are four main circuits from the A.C. low-tension

Digitized by Google

switchboard: to the engineering shop, the boiler shop, the platers' shed, and to the wet basin and pattern shop. All are connected through circuit-breakers, which, in the case of the two latter circuits, are fitted with time-limit relays. From the D.C. board there are six circuits, there being two circuits each to the engineering and boiler shops. The switchboards are of Messrs. Ferranti's make.

The sub-station generally is arranged in accordance with usual practice, except as regards the earthing of

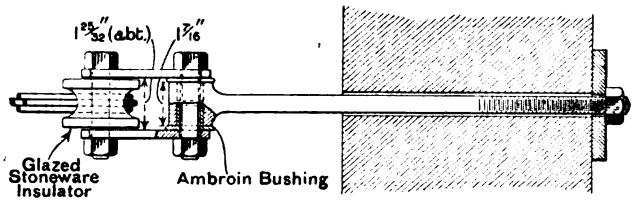

Fig. 2.—Insulator Shackle for Straining Bare Copper.

the neutral point of the A.C. system. The transformers are connected in mesh on the E.H.T. side, and in star on the L.T. side, and the centre-point of the latter is earthed through a nine-ohm resistance through an ammeter. A lamp is connected in parallel with this resistance, and if an earth occurs, the lamp lights up, on account of the drop of potential across the resistance. A switch in the earth connection then enables this to be broken.

The underground mains to the boiler shop and platers' shed are paper insulated with V.B. sheathing (Callender's manufacture), laid solid.

To simplify the arrangement of the overhead cables, a standard size of 0·05 sq. in. section is used generally, one, two, three, or four cables being bunched in parallel as required. The cable is supported on Doulton stoneware shackles with ambroin bushing, so that there is double insulation. Fig. 2 shows the arrangement employed; the long forged bolt on the right is used in three lengths, 7 in. for side trusses, 16 in. for 9-in. walls, and 21 in. for 14-in. walls; and Fig. 3 indicates the manner in which the roof trusses are crossed. Hard-drawn copper is employed. For tee-ing off from the bunches of 0·05 cable, to connect to the various motors, a simple form of gun-metal clip is used, sketched in Fig. 4, and also a special clip made by Messrs. Siemens. The cables to the motors and switches are rubber insulated, and are drawn into solid-drawn seamless tubing. The outside overhead

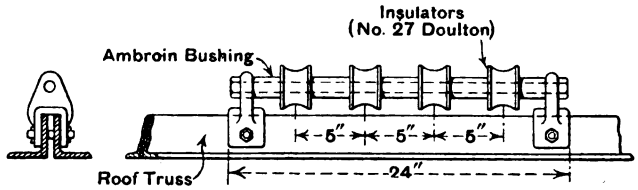

Fig. 3.—Method employed for crossing the Roof Trusses.

cables are, of course, single cables, 2, 3, or 4 single cables (one per pole or phase). They are hung from steel wires by leather tags.

The "tree" system of wiring has been employed in the machine and erecting shops (as seen in Fig. 1), where the disposition of the various machines made this the more convenient method to employ. In the boiler shop there is a simple distributing or "feeder control" board, and in other parts, both inside and outside, Reyrolle distributing boxes are employed.

In a large number of cases the machines have been originally built for motor drive, with the motor bolted directly on to the machine; in others, group driving is employed with belting. Generally, the A.C. motors are of the squirrel-cage type, with auto-transformer starters, but some have star-delta starters. Where electric speed regulation is required for the D.C. motors, separate starting and regulating switches are mostly used. The newer travelling cranes are all operated by Westinghouse three-phase slip-ring motors, as is also a 10-ton jib crane installed in the boiler-

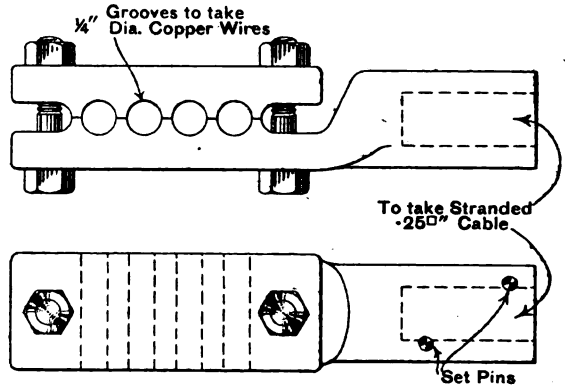

Fig. 4.—Sketch of Clip for connecting to Bunched Overhead Wires in Shops.

shop. The ratings of the motors of these cranes is as follows:—

Ratings of Motors (H.-P.).

Description.	Main hoist.	Auxy. hoist.	Long travel.	Cross travel.
Appleby 50-ton travellers in engine shops	50	30	50	20
Appleby 50-ton travellers in boiler shops	50	30	20	20
Appleby 50-ton in Wet Basin	50	30	50	20
Broadbent 10-ton traveller in boiler shop	20	—	10	10
Broadbent 5-ton in engine shops	20	—	20	10
Broadbent 7-ton at Yard Gantry	20	—	10	10
Arrol 10-ton jib crane in boiler shop	10	—	10 slewing	

For the portable tools, compressed air is mostly employed, this being preferred for the particular purposes

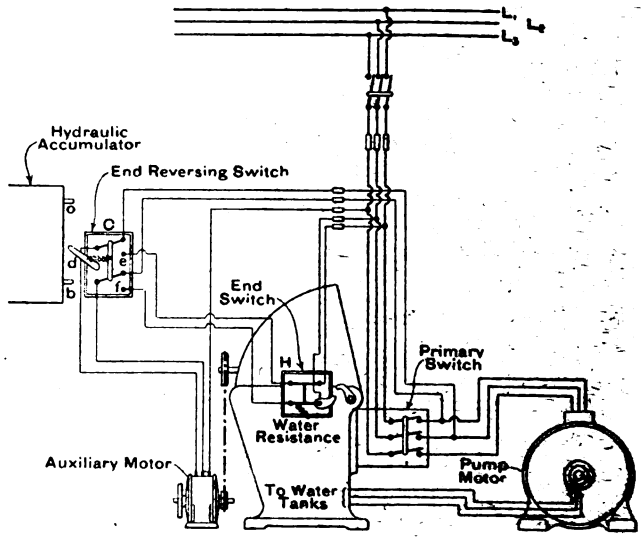

Fig. 5.—Diagram of Connections of Automatic Pump Control.

to which they are put; the compressors are motor-driven, however, four being driven by 50-h.p. motors and one by belt.

A special form of saw for cutting steel sections has recently been put in. The saw-blade is 44 in. diameter, and is mounted direct on the motor spindle. The motor runs at 1,900 revs. per minute, making the periphery speed for the saw four miles per minute.

Digitized by Google

Among the most interesting applications of electric driving is a pump, in connection with a hydraulic accumulator, for supplying power to the various hydraulic tools and appliances throughout the works. This plant was supplied by the British Westinghouse Co. The motor driving the pump is rated at 75 B.H.P., and is started automatically when the accumulator falls below a certain level. The motor is a slip-ring induction motor, and the arrangement of the connections will be understood by reference to Fig. 5. When the accumulator falls to a certain point, a pin, *o*, moves the trigger *d* of the reversing switch *C*, and the blades of the switch make contact with *e* and *f*. This closes the circuit of an auxiliary motor, of about ¼ h.p., which gradually lowers the plates of the water resistance, and closes the primary switch in the stator circuit of the main just before the plates touch the liquid. The water resistance is in the rotor circuit of the main motor, so that the motor is started. As soon as the

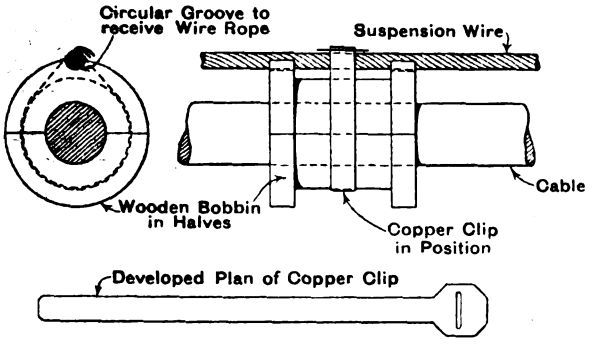

Fig. 6.—Teak Insulator for Suspending Overhead Cable (Half-size.)

blades of the water resistance reach their limiting position, and the rotor winding is short-circuited, the switch *H* controlling the circuit of the auxiliary motor is automatically opened. When the accumulator rises again to the point at which the pump is to be stopped, the pin *b* comes into operation and sends over the reversing switch so that the auxiliary motor is driven in the opposite direction, the connection this time not being made through the switch *H*. The motor winds up the plates again, and near the end of the stroke the primary switch is automatically switched off, and the switch *H* is switched on again, ready for the next operation. The connections are such that the auxiliary motor is disconnected from the circuit as soon as the primary switch comes off, and it therefore stops at the same time as the main motor. In order that the motor should not be started against the full load, a bye-pass valve has been fitted to the pump, and this is also mechanically connected to the liquid starter, and is gradually closed, so that by the time the motor is running at full speed, it has also the full load to deal with.

An electrical department not seen in all engineering works is a galvanising shop, in which the boiler tubes are galvanised. Current is supplied to the galvanising tank by a small motor-generator which can give 2,500 amperes at five volts. The boiler tubes are first treated in a pickling tank, then in a sand tank, in which they are cleaned, and finally in a washing tank before going into the plating tank. After galvanising, they are washed, and are tested by water pressure to 1 ton per sq. in.

Some masts 60 ft. high have recently been erected for arc lamps for the lighting of the shipbuilding berths, the lamps being fixed a sufficient height above the level of the boat's deck to provide illumination at the deck level. For the lighting mains for the arc-lamp masts in the yard a system of suspension is used, indicated in Fig. 6. The cable is passed through split wooden bobbins, which are attached to steel suspension wire by a light copper clip. The advantage of this arrangement is that there is no swinging and chafing of the cable.

The lighting in the general offices is by Crompton inverted arc lamps, taking D.-C. current at 210 volts. A 14-kw. motor-generator has been installed, so that current can be provided for these arc lamps after ordinary working hours without having to run the main motor-generator.

A point of interest is the Synchronome clock system, which has been adopted throughout the premises. There are twenty-two dials and one controlling pendulum, the dials being actuated by the completion of an electric circuit twice per minute by the movement of the controlling pendulum on the Synchronome Co.'s usual system. The May-Oatway system of automatic fire alarms is another of the miscellaneous applications of electricity adopted at the works.

The electrical equipment of the works was carried out by Messrs. Yarrow's own staff under the superintendence of Mr. R. D. Keay; and Mr. P. F. Allan (who has since joined the Clyde Valley Electric Power Co.) was responsible for the detail of the electrical work. Messrs. Yarrow were courteous enough to allow us to inspect their works recently for the purposes of this article.

Exhibition of Scientific and Engineering Models.—A model engineering exhibition will be held at the Royal Horticultural Hall, Westminster, S.W., from October 15th to 23rd. Model aeroplanes, steam and electric railways, electric clocks, light machine tools, model motor-boats, a model engineers' workshop in operation, and a demonstration of Marconi wireless apparatus are some of the attractions. The exhibition will be open from 12 noon till 10 p.m. each day.

Electric Traction for the Mont Cenis Tunnel.—It is reported that the Italian State Railway authorities have decided upon the adoption of electric traction through the Mont Cenis tunnel and on other portions of line where the gradients are considerable, with a view to improving the service from Modane to Turin. For this purpose the Municipality of Turin is being approached regarding placing a 3,500 k.v.a. set in the Chiomonte generating station on the Dora Riparia at the disposal of the railway for a guaranteed payment of £8,000 per annum.

Manchester Municipal School of Technology.—The third issue of the *Journal* of this Institute, which is a record of investigations undertaken by members of the teaching staff and by students of the several departments of the school, contains a series of abstracts of Papers, articles, and communications to scientific societies published between 1905 and 1908, and dealing with investigations carried out in the various departments. The work published in 1908 will be reprinted in full in the next issue, and it is hoped that the collected Papers of the following years will appear in the *Journal* within a short time of their original publication.

Tungsten Lamp Patents in America.—According to the *Electrical World*, the General Electric Co. of America has concluded an agreement with the Bergmann Elektricitäts Werke of Berlin, whereby the latter company has sold to the General Electric Co all the American patent rights covering its tungsten lamps (sold in Germany under the name of the Bergmann "Fulgura" lamps) for a period of ten years. The Bergmann Elektricitäts Werke will not establish a lamp factory in America as proposed, and the "Fulgura" lamps will only be imported under licence of the General Electric Co. within that period. It may also be noted that the General Electric Co. have acquired the Just-Hanaman and Kuzel patent rights in America, so that the company has a strong hold on the American tungsten lamp business.

East London Electrical Exhibition.—At the invitation of Mr. C. Newton Russell, Electrical Engineer to the Borough of Shoreditch, a meeting of exhibitors was held at the electricity offices, Coronet Street, Hoxton, on September 30th, when the following Committee was appointed: Mr. F. Pooley, Chairman; Mr. H. Harrison, Vice-Chairman; Mr. E. P. Barfield, Mr. T. Lambie, Mr. S. Rentell, Mr. H. Dixon, Secretary, 11 Victoria Street, Westminster, S.W. It was announced at the meeting that nearly all the available space had been taken up, and, therefore, any firms in the industry who are desirous of exhibiting, and have not yet secured space, should communicate at once with Mr. Russell. The Secretary of the Exhibitors' Committee will be pleased to receive any suggestions, &c., from exhibitors which they may wish to be brought before the Committee.

ELECTROMETALLURGY AND ELECTROCHEMISTRY

DR. EUGENE HAANEL has issued an interesting report to the Canadian Department of Mines on the working of the electric stack furnace at Domnarfvet, in Sweden. During recent years very great development has taken place in the manufacture of electrodes for electric furnaces. The raw material varies considerably, depending upon the use to which the finished electrodes are to be placed. The simplest and the cheapest electrodes are made of anthracite, retort carbon, and tar. For higher grade electrodes graphite is also added to this mixture. The anthracite employed requires to be of good quality and is usually hand-picked. The anthracite is first ground roughly and then in edge-runners. The whole of the raw material is not ground to the same degree of fineness, the size of the grain varying very much. The mixture of powders of different degrees of fineness is then thoroughly incorporated with tar; it is important for the subsequent burning treatment that the tar should be free from water, and for this reason it receives a preliminary heating, and is added warm, so that it may be thoroughly fluid. After standing for some days the material is pressed into shape in such a way that the excess of tar is forced out. After leaving the press the electrodes are air-dried for some days and placed in the kiln. Modern factories have a special ring series of kilns, which are somewhat similar to those used for firing bricks at high temperatures. The heating is carried out by means of generator gas, and special arrangements permit of the heating of the various chambers independently.

The British Aluminium Co. have recently constructed an electrode factory at Kinlochleven, having a capacity of 6,000 tons a year. Particulars with cost are given of a 3,000-ton plant, approximately corresponding to the conditions to be met with in Canada. For Canada anthracite coal, retort carbon and coal tar would be probably most suitable. The cost of anthracite is about the same as gas carbon, namely, £2 per ton; that is because some parts of the retort carbon always require to be discarded; otherwise it would be rather cheaper. The labour required is variable, depending upon whether much labour-saving machinery is employed. The actual number of skilled men for the furnaces and machinery should not exceed fifteen for a 3,000-ton plant. The total operating expenses, exclusive of general administrative costs, is put down as follows :—Electrode machinery, such as crushing, mixing, moulding, &c., at £8,000; cost of factory, £50,000; labour, £3,060; annual expenses of material, £78,000. It is interesting to note the length of time required to carbonise the electrodes, which is probably longer than most people would imagine. The highest temperature of the kilns should be about 1,410° C., and the electrodes should remain in it for from twenty to twenty-two days.

According to *Electrical and Metallurgical Industry*, the electrochemical industry in the States would appear to be in a flourishing and advancing condition, to judge by the large amount of electrodes which are just now being manufactured. But the increased demand for electrodes of large size such as are used for furnace work has made demands upon the inventive genius of the makers. The baking of large-size electrodes of amorphous carbon, so as to give them the same durability and strength as electrodes of smaller size, is a difficult problem. Graphite electrodes are more expensive, but they are very durable and permit of easy machining. For this reason there is practically no waste at the ends, a new length of electrode being readily screwed into the end of an old one. Another point is that graphite electrodes are not so readily oxidised, and they are better conductors of heat.

From the *Sheffield Daily Telegraph* we note the following report of a new electrolytic process. At a meeting of the Rhodesia Broken Hill Development Co. recently, in London, the question of ore treatment was discussed, and it was reported that preliminary trials, recently made at Sheffield, of an electrolytic process had been considered by the company's consulting engineers sufficiently encouraging to warrant the erection of a plant with a view to treating a considerable quantity of ore on a working scale. Orders have been given for a complete plant, and this would be erected on a site which had been secured in London. About 180 tons of ore have been secured for the purpose of the experiment, and should the results be satisfactory it was proposed to form a process company to acquire the patent rights for the whole of Rhodesia.

In a report on the iron and steel industry of the Transvaal, by the Government Mining Engineer, abstracted in the *Iron and Coal Trades Review*, it is stated that a recommendation has been made that the Central South African Railways should establish an experimental electric furnace for working up scrap if the Government will pay half the cost of the experiment, which is estimated at £30,000.

RECONSTRUCTION OF THE ALDGATE-BOW TRAMWAYS

Improved Method of Changing Ploughs.

TRAFFIC has now been running for some time on the Aldgate-Bow line of the London County Council Tramways since its reconstruction, partly on the conduit system and partly on the overhead trolley system. The actual construction of the conduit work is in accordance with the standard practice of the L.C.C. Tramways, such as has been often described before (*see* ELECTRICAL ENGINEERING, Vol. I., page 9); nor is there any special feature of the overhead section to call for remark. Some interest, however, attaches to the arrangement adopted at the junction of the two systems for extracting and re-inserting the ploughs of

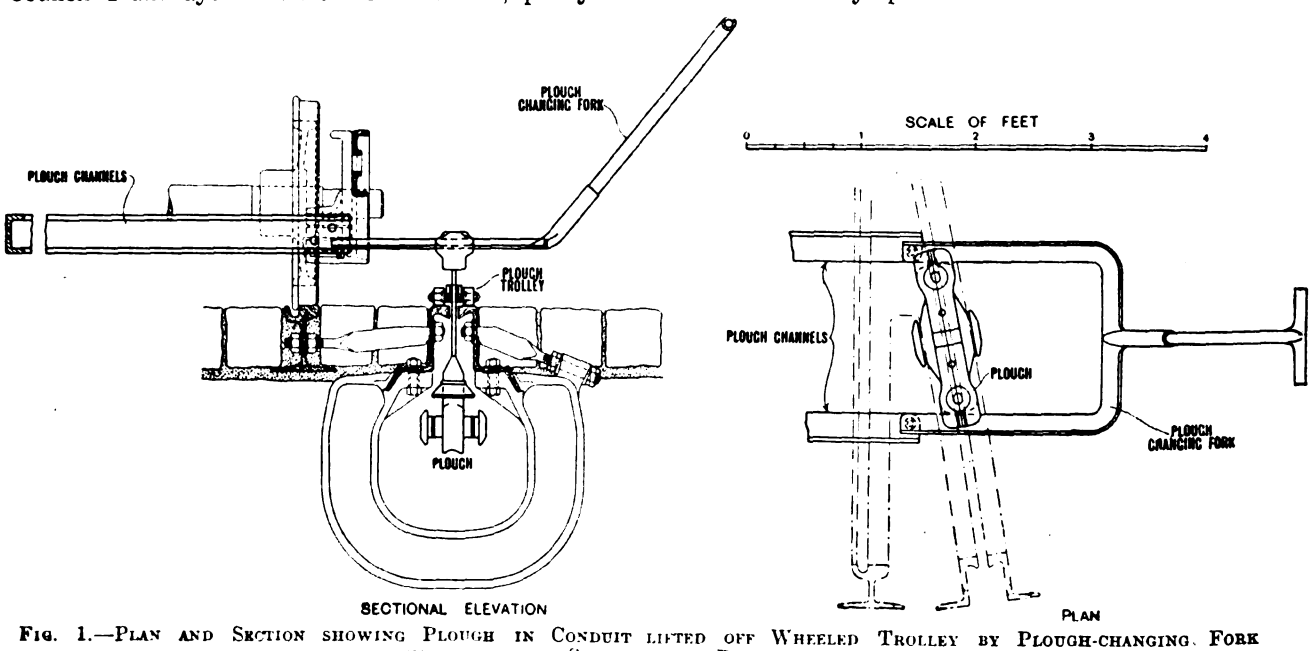

FIG. 1.—PLAN AND SECTION SHOWING PLOUGH IN CONDUIT LIFTED OFF WHEELED TROLLEY BY PLOUGH-CHANGING FORK AND READY FOR SLIDING INTO POSITION.

Digitized by Google

the cars as they leave or enter the conduit section, as this embodies several improvements upon the method described in our columns in connection with the Denmark Hill-Brixton line (*see* ELECTRICAL ENGINEERING, February 4th, 1909, page 107). Before, however, describing the arrangement employed, a few notes on the circumstances which led up to the employment of these systems on this piece of line will not be out of place.

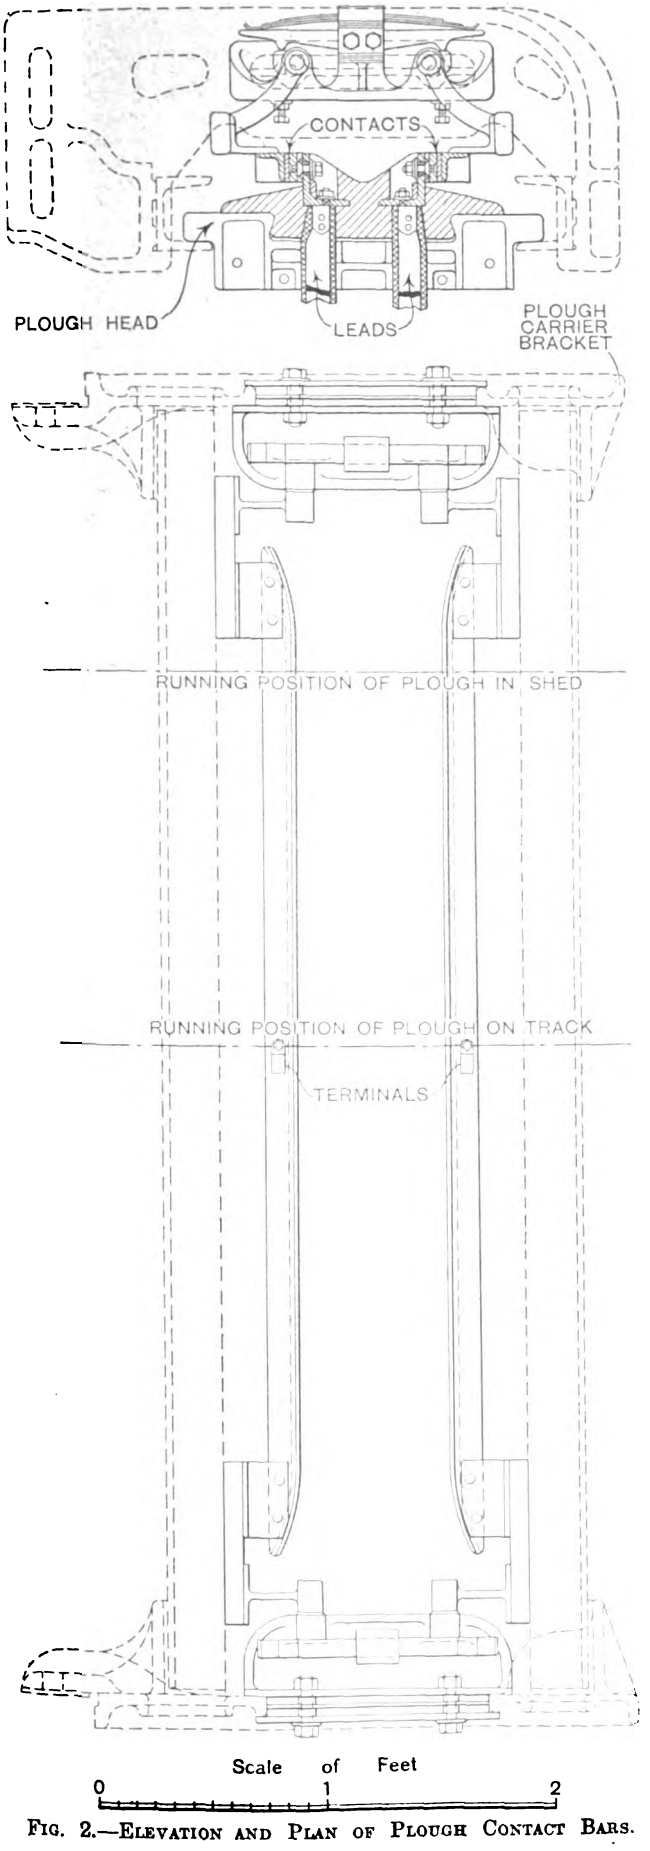

FIG. 2.—ELEVATION AND PLAN OF PLOUGH CONTACT BARS.

By the London County Council Tramways (Electrical Power) Act, 1900, the Council is precluded from using the overhead trolley system of electric traction except with the consent of the road authorities concerned, *i.e.*, the Metropolitan Borough Councils. Every effort has been made with regard to certain of the tramway routes, which, it appeared, would be suitable for this system of traction, to secure the consent of the road authorities, but without success, and the most conspicuous instance of non-success is in connection with the Aldgate-Bow line, the road authority for the greater part of which route is the Stepney Borough Council. This authority has constantly, since the County Council acquired the horse tramway system of the North Metropolitan Tramways Co., refused to entertain the overhead system, an attitude which has been instrumental in delaying the reconstruction of this route for electric traction. The available depth, however, between the roadway and the roof of the tunnel of the Whitechapel and Bow Railway was insufficient at one or two points for the installation of the standard conduit system without raising the level of the road, and the County Council at that time did not consider the expense of this justifiable, and it was for this reason that any serious attempt to deal with the question was delayed until 1907, when, it will be remembered, the Highways Committee of the County Council recommended the adoption, experimentally, of the G.B. surface-contact system. It is not necessary to recapitulate here the circumstances which led the County Council to condemn the G.B. system, and finally to decide upon its removal. Owing to the continued opposition of the Stepney Borough Council, the overhead system could not be installed, so on the section from Gardiner's Corner to Burdett Road the conduit system has been put in, and the road level has been raised at one or two points by as much as a foot where the tunnel of the Whitechapel and Bow Railway is near the surface. The overhead system has, however, been installed from Burdett Road to Bow Bridge, as the latter section is within the area of the Poplar Borough Council, who raised no objection to its employment.

The most important feature of the new method of detaching the plough is that the necessity for a man to reach under the car to uncouple the flexible plough leads is avoided.

A pair of transverse contact rails hung on springs are provided under the car, so that the sliding off of the plough in a sideways direction automatically disconnects it, and, *vice versa*, the insertion of the plough carrier into its slide automatically connects it up. So far as the removal of the plough is concerned, therefore, it is unnecessary to stop the car, as the plough slides out sideways where the slot rail crosses the running rail, and is left in the road clear of the car. In practice, however, a short stop is made to place the trolley on the wire. The same arrangements for leading the abandoned plough off on a little wheeled truck to a refuge, and to a car coming in from the overhead section are made as in the case of the Denmark Hill plough change points described in the article referred to. On the approach of a car a plough on its little truck is pushed to the part of the slot parallel to but just outside the running rail, where the car is stopped. The attendant then hooks the plough-changing fork with which he is provided into the plough channels, so that it virtually forms an extension to them, and levers up the plough off its trolley to the position shown in Fig. 1. The car then proceeds slowly while the attendant still holds up the handle of the fork, and the obliquity of the slot slides the plough on to its carrier. The car is then stopped, momentarily, the fork is removed, and the car is free to proceed. As soon as it reaches the slot conductors, the trolley-boom is hauled down.

The contact arrangement is shown in detail in Fig. 2, and consists essentially of a pair of contact rails attached at each end to radial spring controlled swinging brackets, from which they are, of course, insulated. They thus not only bear firmly upon the contacts on the head of the plough, but accommodate themselves to its position.

In conclusion, we should express our thanks to Mr. A. L. C. Fell, Chief Officer of Tramways to the London County Council, for placing at our disposal information and drawings for the preparation of this description.

National Electrical Manufacturers' Association.—The next committee meeting will be held on Tuesday, October 12th, at Balfour House, Finsbury Pavement, London, at 2.30.

International Electrical Exhibition.—The *Elektrotechnischer Anzeiger* states that endeavours are being made to arrange for an international electrical exhibition in Dresden in 1913.

Tax on Electricity in Italy.—The Italian excise returns for the financial year 1907-8 show that the tax on electricity and gas yielded a revenue of £426,670.

Digitized by Google

WATER POWER STATIONS

THE reckless waste of coal in this country, both by extravagant use and by unrestricted export, will continue for many years before attention is seriously directed to the use of water power. It may be pleasant to point out that the Newcastle and Durham district enjoys a cheaper and better supply of electric power than the district round Niagara, but this cannot last for long. Depletion of our mines is inevitable, and other causes which need not be mentioned may drive coal up to £3 per ton before the machinery that is being made to-day is worn out. The Governments of the United States and of certain Continental countries have taken steps to develop water power resources by protecting water-sheds and by rigid enforcement of forest preservation laws. It is difficult to imagine our Government doing anything so useful, and the excuse for them is ready to hand, namely, that the water-power of this country is not worth worrying about. The capital cost per horse-power of what is sometimes called hydro-electric plant far exceeds that of steam plant, and while the working expenses of the former consist mainly of labour or rather superintendence, the interest on the capital is the main factor of the cost. With the ancient solitary and unfortunate exception of Worcester, no municipality has attempted to generate electric supply from water-power, nor is it likely that such bodies will have the chance in the future. It has been said that Nature beneficently arranged that important rivers should flow through important towns, but she rarely places a good head of water near the place where power is wanted. Hence transmission lines are as important a section of engineering as turbine setting. While a municipal authority will go a long way to get a water supply, it is not likely to draw its power from another district. The development of water-power in this country—what there is of it—will probably be a matter of private enterprise, and in these days those who have the heart to sink capital and venture on such work are likely to do so in some other part of the globe. Snowdon is an exception, and Snowdon has not been a success, though the difficulties have had nothing whatever to do with the generating plant nor the transmission of the power. It is doubtful if another high fall so suitable for the purpose will be found in these islands, and it is probable that attention will have to be given in the future to the less attractive use of low falls.

The Mining Institute of Scotland.—It is announced that the meeting intended to be held on Wednesday next, 13th inst., has been postponed.

Electrification of Victorian Railways.—An action against the Crown by F. E. Bradford, an electrical engineer, was heard recently at Melbourne, in respect of the electrification of the Victorian Railways. The plaintiff claimed that an arrangement had been entered into by them in 1904 with Sir Thomas Bent, late Premier, that he (plaintiff) should inquire into and report to the Victorian Government upon the electrification of the Melbourne suburban railway system for the sum of £1,700. Mr. Bradford claims to have been prevented from carrying out this contract, and it will be remembered that Mr. C. H. Merz subsequently went out to Australia from England and presented a report. After a lengthy hearing the jury disagreed, and were discharged.

North Midland P.O. Engineering District.—We understand that a change of considerable importance has been decided upon by the postal authorities in reference to the future control of electrical engineering arrangements of the North Midland district. For many years Nottingham has formed the headquarters of a widely scattered area, including parts of Yorkshire and Staffordshire, and the whole of the counties of Nottingham, Lincolnshire, Leicestershire, Derbyshire, and Rutlandshire. After December 1st this territory will be absorbed by the Leeds and Birmingham districts, opportunity being afforded to the existing staffs at Nottingham of transferring to other centres of administration. The change is coincident with the approaching retirement under the age limit of Mr. T. J. West, the present electrical superintendent, who has completed forty-five years' service.

WIRELESS TELEGRAPH NOTES

IN the House of Commons on Thursday, the Postmaster-General stated that arrangements have been completed with Marconi's Wireless Telegraph Co. for the transfer to the Post Office of all their coast stations, including all plant, machinery, buildings, land, and leases, &c., and for the surrender of the rights conferred under their agreement with the Post Office of August, 1904, for licences or facilities in respect of coast stations. Further, the Post Office secures the right of using, free of royalty, the existing Marconi patents, and any future patents or improvements, for a term of 14 years, for communication for all purposes between stations in the United Kingdom and ships, and between stations on the mainland of Great Britain and Ireland on the one hand, and outlying islands on the other hand, or between any two outlying islands; and (except for the transmission of public telegrams) between any two stations on the mainland; and on board Post Office cable ships. The inclusive consideration to be paid to the company is £15,000. All the stations will, under the International Radio-telegraphic Convention, be open for inter-communication with all ships, and the Post Office will be free to use or to experiment with any other system of wireless telegraphy. All inland communication will be entirely under the control of the Post Office. The company will retain the licence for their long-distance stations at Poldhu and Clifden. Arrangements have also been made with Lloyd's for the transfer to the Post Office of their coast wireless stations, and for the surrender of all claims to licences for such communication. In return Lloyd's will receive the plant value of their stations, and will have transmitted to them (with due regard to the secrecy of private telegrams) information received at the Post Office stations in regard to the position and movements of ships, and other maritime intelligence. Lloyd's and the Marconi Co. have arranged to cancel an agreement between themselves which was made in 1901. The Postmaster-General added that in his opinion it was to the public interest, from all points of view, that the coast stations should be in the hands of the Government, and should be worked as part of the general telegraphic system of the country. The negotiations and arrangements have been conducted with the concurrence of the Admiralty. In answer to questions the Postmaster-General stated that the claims of the present employees would be taken into consideration by the Government. In the event of an outbreak of war the Government had power to take over the Poldhu and Clifden stations.

It is stated on the authority of Mr. Marconi that the Marconi Co. contemplate the introduction of a special rate of 3d. per word for transatlantic wireless commercial messages not in code.

The Times states that the Zeppelin III. made two ascents at Friedrichshafen on Wednesday last week for the purpose of testing its wireless telegraphy installation. The airship conducted its experiments successfully for four hours and a half altogether, at a height of from 400 to 800 metres.

It is announced that the magnetic storm last week did not in the least affect the Marconi wireless telegraph stations or their working.

A Reuter telegram from Simla states that the Indian Government recently issued an order making the importation of wireless telegraph apparatus contraband. It is now understood that the Government is considering a scheme to provide important centres with a wireless system worked entirely under European control. It is believed that Lord Morley will shortly be addressed on the subject.

It is announced that the Cuban Government has come to an arrangement with the United Fruit Company to erect wireless stations on the coast of Cuba.

It is stated that the United States Government have placed an order with "a company of Pittsburg" for the erection of a wireless telegraph station having a range of 3,000 miles, for £36,000 for the machinery. The tower is to be built under a separate contract. If the requirements of the contract are not met in every particular, £20,000 will be forfeited.

Electrical Exhibition at Hampstead.—An exhibition of domestic electrical appliances was opened at the Public Baths, Finchley Road, by the Mayoress of Hampstead yesterday afternoon, and will remain open till Saturday. The exhibits include heating and cooking apparatus, electrically-driven vacuum cleaning apparatus, fans, motors, electric signs, electric pianos, &c., and the Hampstead Corporation Electricity Department have an inquiry bureau.

The Status of the Engineer.—In the course of a Paper before the Society of Engineers on Monday, entitled "How to Improve the Status of Engineers," Mr. G. Allan Thomas suggested that there should be a central organising body, composed of representatives of the Institutions of Civil, Mechanical, and Electrical Engineers, which should be duly incorporated. It should direct attention to the registration of members, to a scheme of education, the establishment of a scale of fees for consulting engineers, the provision of funds to aid invention and research, an information bureau, and the institution of benefactions for needy members.

THE WELSBACH CO. AND THE METAL FILAMENT LAMP

THE letter from the Managing Director of the Welsbach Incandescent Gas Light Co., Ltd., which we publish in our Correspondence columns, shows that the company do not wish to be drawn to make any statement whatsoever as to the question of patents in reply to the criticisms that appeared in our issue of Sept. 23rd. Our readers must for the present be content with the information that the lamps sold by the Welsbach Co. are certainly not "Osrams," but are a different make of tungsten lamp, manufactured in Germany, and generally similar in appearance, candle-power, and wattage to other tungsten lamps on the market. On the other hand, with regard to the arrangements which the Welsbach Co. is making with wholesale and retail lamp firms, and also with wiring contractors and consumers, we are able to give full information. So far as the sale of the lamps is concerned, no attempt is being made to cut the retail price of the lamps, which is the same as that of those with which it is competing. The Welsbach Co., we understand, does not limit its business to its existing agents, but will be prepared to supply lamps to any firm of lamp dealers or wiring contractors on a trade basis. The offer to replace consumers' carbon lamps with metal filament lamps, and to accept in payment a sum equivalent to the reduction in the consumer's electric lighting bill, is also made to any lamp dealer or contractor. Consumers who write to the company to say that they are desirous of profiting by the offer advertised are asked to give the name of their lamp supplier, and, if the company is satisfied that the firm is a respectable one, the order is passed on to him, and he carries out the work and makes the necessary arrangements for the collection of payment on the basis advertised. At any rate, up to the present, we understand, no particular form of agreement with the consumer has been drawn up by the company, and the agent who supplies the lamps is left a free hand in this respect. Moreover, the company is prepared to indemnify the consumer and agent against patent proceedings. The Welsbach Co.'s offer only extends to the replacing of carbon lamps by metal filament lamps, and does not include making any change in the consumer's wiring, or any other alterations or additions to the consumer's installation.

A NEW TELEPHONE TRANSMITTER

LAST June the announcement was made that successful experiments had been carried out with a new telephone transmitter which had enabled conversation to be carried on between Stockholm and Paris over a 4·5 mm. line about 2,500 miles in length. The new transmitter was the invention of Mr. C. E. Egner, Chief Engineer of the Stockholm telephone administration, and Mr. J. G. Holmström. A patent (No. 12,918 of 1909) by these two gentlemen for a telephone transmitter, which is in all probability the instrument in question, has just been published, and we are thus able to describe its chief features.

The principle upon which the instrument is based is that the diaphragm is so clamped that there can be no doubt that the point of greatest vibration is exactly at the centre, and the front disc of the microphone (which is not in this instrument formed by the diaphragm itself) is so fixed to the diaphragm that its entire surface moves with this maximum amplitude. This arrangement is indicated in Fig. 1. The method of clamping the diaphragm *D* with an additional clamping ring is clearly shown, as is also the attachment of the front disc *E* of the microphone, which, it is seen, is devised in such a manner that the movement of the ends of the disc is the same as that of the centre.

As an alternative form, a multiple transmitter is described, in which a number of microphone cells are employed fixed at several points round a disc *F*, as shown in Fig. 2 (in which, however, one only of the microphone cells is shown so as not to confuse the sketch). There will thus be absolute synchronism between all the cells. The thin cylinder connecting the disc *F* to the

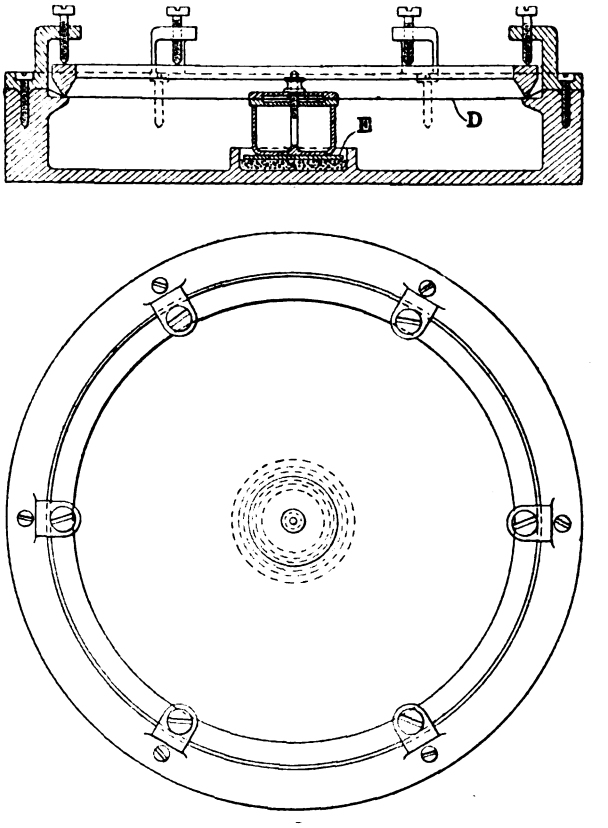

FIG. 1.

diaphragm is of steel, and is perforated to save weight and also to assist cooling. The cups containing the carbon granules are supported in such a way that by rotating the ring *G* their height can all be adjusted simultaneously, while the screw *H* affords a means of adjusting each cell separately.

It may be mentioned that in a previous patent (No. 6,587 of

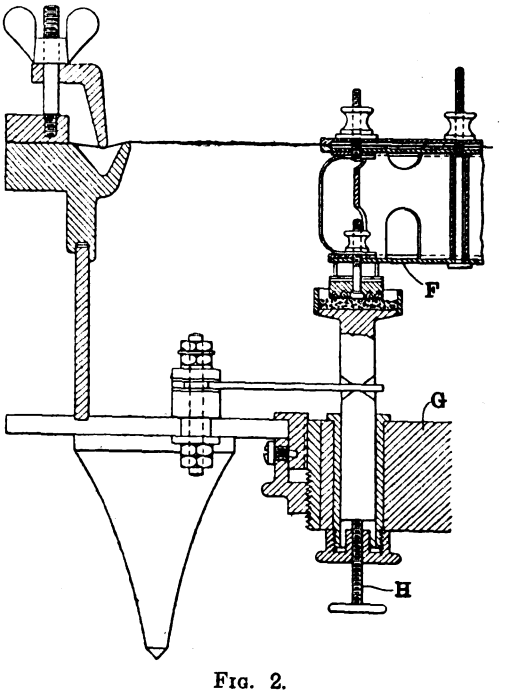

FIG. 2.

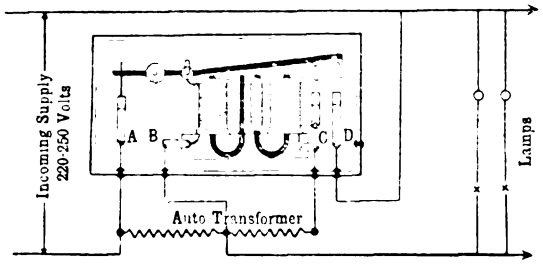

1908), the only other patent taken out by these inventors during the past few years, a microphone is described in which the chamber containing the granules is hermetically sealed, and contains hydrogen or a hydrocarbon gas instead of air.

NEW AUTOMATIC TRANSFORMER SWITCH

A NEW design of automatic switch, for use in connection with lighting installations supplied through auto-transformers for saving the no-load losses of the transformer during the periods when no artificial light is required, has been placed on the market by Messrs. D. Burr & Son (85 Gracechurch Street, London, E.C.). This switch has been brought out especially for use on small installations where a large outlay is not warranted. The price for the 250-watt size is only 32s. 6d., subject to a substantial discount to the trade, and the apparatus is said to save its cost in less than one year. The general design of the switch and the necessary connections are shown in the accompanying figure, which indicates the conditions with no lamps on.

It will be seen that no part of the auto-transformer is connected to the supply, but that directly any lamp is switched on a circuit is completed through that lamp and the high-resistance coil on the left-hand electromagnet through the connections *A* and *B*. The completion of this circuit causes the magnet to be energised and the horizontal arm to tilt over, so that the circuit is broken at the mercury cup *A*. The momentum of the arm carries it completely over, however, and the main transformer circuit is completed through the mercury cups at *C* and *D*; this energises the series coil on the right-hand electromagnet, and the switch-arm is held over in the closed position. The turns on the two magnet coils are so adjusted that the switch operates when a single 16-watt metal filament lamp is switched on or off. Although the two iron magnets and the arm are not laminated, the flux densities are so low that the hysteresis loss is negligible. Sticking is avoided by inserting a stop of a non-magnet metal in the face of the series-coil magnet pole to prevent contact of the iron surfaces, and the

Automatic Transformer Switch for Small Lighting Installations.

use of a copper wire damping coil closed on itself and placed on the second limb of the right-hand magnet effectualy prevents rapid variations in the magnetic flux, and therefore obviates humming due to vibrations of the arm. It will be noticed that when the last lamp is switched off, the magnetising current of the transformer still passes through the series coil. This is not sufficient to hold the arm over against the action of the counterweight, however, and this arrangement is said to have the advantage of preventing the series coil being left magnetised as the small current flowing after the last lamp is switched off demagnetises it immediately.

The switch is built up on an oiled slate slab and mounted in a cast-iron case with a glazed front, to enable one to see that it does not stick. Porcelain bushes are provided for the incoming leads. The case is provided with lugs so that it may be easily attached to the wall in any convenient position between the main switch and the main distribution board. The connection from terminal *D* can be taken back to the main switch is desired, but if this is inconvenient, an extra porcelain leading-in bush has been provided so that the main may be looped into this terminal without the necessity of making a joint. The apparatus can be supplied to work on circuits of all usual voltages and frequencies, and in the 10-amp. size, which is the only size manufactured at present, the drop in the series coil is negligible. A design for larger sizes up to 2-kw. is now being developed, and it has been found necessary in these to provide a relay, as if the series coil is to pull on with one lamp the voltage drop at full load becomes very serious.

Parliamentary.—The Edgware and Hampstead Railway Bill was read a third time and passed in the House of Lords on Tuesday

Association of Engineers-in-Charge.—The opening meeting of the session will be held at St. Bride's Institute, Fleet Street, London, on Wednesday next, at 7.30 p.m., when Mr. Henry Adams will deliver his Presidential Address on "Standardisation." Among the Papers which have been arranged for are the following:—"Recent Developments in Impulse Steam Turbines," by R. Andersson and E. Meden; "Modern Arc Lamps and their Application," by A. Angold; "The Application of Recording Instruments to Steam Generation," by Jacques Abady; "Welding and its Application," by R. J. Wallis Jones.

THE TRAINING OF ELECTRICAL ENGINEERS

PROFESSOR J. A. FLEMING, F.R.S., delivered an introductory lecture at University College, Gower Street, yesterday afternoon, on the occasion of the opening of the Engineering Department of the College for the new session. The Chair was taken by Mr. W. M. Mordey, President of the Institution of Electrical Engineers. In the course of an eloquent address, Dr. Fleming sounded a warning note against premature specialisation on the part of the student, and said that it was of the utmost importance to lay the foundation broadly, not merely in technical but also in business knowledge. For this reason he was opposed to any attempt to introduce engineering into school curricula; but, on the other hand, he expressed the view that the time and thought given to games at our public schools was excessive. Far greater things should be accomplished in the way of knowledge of foreign languages, mathematics, and acquaintance with science generally, and more power also ought to be obtained of expressing ideas in good lucid English. Before assuming that the engineering profession was the most suitable for any particular boy, it was necessary to consider among other things what prospect there would be of his being able to obtain subsequent remunerative employment. Parents should also realise that a mechanical turn of mind, or a fondness for carrying on domestic electrical experiments, does not necessarily show a natural aptitude for engineering. With regard to the training, examinations were not to be regarded as the ultimate object. A certain amount of stored or remembered information was necessary, but to store it merely to prove that you have stored it tended, he said, to paralyse the powers of initiation. The foundation of special technical training should consist of a thorough preliminary education in pure and applied science, after which the student enters on the study of the application of scientific knowledge to technical work. In the laboratory, the student is trained to record results of observations, to gain accuracy in measurements and to draw correct conclusions from the results; but lecture and laboratory teaching were shockingly wasted unless the student gave an equal amount of time to preparation for it, and to subsequent elaboration of his notes. He was not one who considered that degrees in engineering were of supreme importance. On the other hand, the preparation for a degree sometimes afforded a useful spur and gave a definiteness to a student's work. He suggested that there was a serious need for reform in the syllabus of the London engineering degree. The present syllabus was not so constructed as to compel every candidate to lay a sufficiently broad foundation of elementary knowledge in all branches of engineering science, and left the student to pick out any five of eleven subjects without regard to each other or to engineering as a whole. Again, there was no practical examination, but merely answers on paper; and, in the third place, the degree could be obtained, he said, without the very slightest knowledge on the part of the candidate of electrical technology, and he mentioned many examples showing how necessary some electrical training was to engineers of practically every class.

The young engineer should not at first pin himself down too closely to any one branch of the profession, although a selection had to be exercised at a certain stage. With regard to electrical engineering, there were three or four well-marked divisions, each of which required a special preparation. The Post Office had lately thrown open certain appointments to college-trained graduates, and wireless telegraphy now afforded openings to men of good physique and education. In the case of electric supply for traction and lighting, it was also absolutely requisite to have received some practical training in an engineer's shop, but success in this work was not merely a matter of engineering knowledge, but, as far as the higher positions were concerned, required considerable organising business abilities. With regard to electrical manufacturing work, the custom of taking technically untrained young men at a large premium into works had been to a large extent discontinued. The leading electrical engineering firms now preferred to secure men with a thoroughly good scientific and technical training, who would be more immediately useful. Hence the necessary adjunct of the college or university training was workshop experience.

Professor Fleming then proceeded to mention some of the special features of the arrangements at University College, and spoke of the necessity for organisations for putting those who had finished their college course in touch with their employers. In conclusion, he considered briefly some of the features of the present position of electrical engineering and some of its future prospects. He took as examples of the influence of electrical engineering upon world problems, the growing industry of the extraction of nitrogen from the air electrically for the production of fertilisers. Looking into the future, there would perhaps be developments in the direction of wireless transmission of power enabling sources of energy at present untouched to be utilised. He also indicated a number of more prosaic directions in which the work of future electrical engineers might be directed, and said that these examples showed that in the engineering profession a young man with ideas and originality had great opportunities of doing work which would obtain speedy recognition and reward.

E.S.C. SPECIFICATION FOR AMMETERS AND VOLTMETERS

A STANDARD Specification for Ammeters and Voltmeters (No. 49) has just been issued by the Engineering Standards Committee, which seeks to define the degree of accuracy which can reasonably be demanded for various classes of instruments, and to standardise ranges, &c., in a way which should save considerable trouble in tendering, and by increasing uniformity in detail work should tend to cheapen production.

In the specification, instruments are classified as sub-standards, first-grade and second-grade instruments, according to their accuracy. For example:—a sub-standard voltmeter is required to have an accuracy within ±0·2 per cent., and a sub-standard ammeter an accuracy of ±0·5 per cent., of the maximum scale reading. A second-grade instrument is only required to have an accuracy of ±2 per cent. for a voltmeter, or ±4 per cent. for an ammeter (at and above the middle point), and should be useful in workshops, &c., where accuracy is not of vital importance. The Committee make certain definite recommendations for the construction of instruments which comply with the British standard. Recommendations are also made with reference to scales, although no particular sizes for the figures are mentioned. An important part of the specification is the schedule of standard scale readings for ammeters and voltmeters, which have been selected with a view to cheapening production by reduction of the numbers of patterns which have to be kept in stock, while at the same time keeping the requirements of purchasers in view.

The drop in pressure on the shunt has been standardised at 0·075 volt in order to obtain interchangeability, but it should be noted that the value chosen is different from the German standard. The secondary pressure of a potential transformer has been fixed at 100 volts, and the current in the secondary circuit of a series transformer at 5 amperes at maximum scale reading. The committee explain in the preface that they have not gone further into the questions affecting instrument transformers, as they intend dealing in a separate report with standards for instrument transformers, resistances, and separate shunts. The clause relating to insulation is as follows:—"The insulation resistance between the electrical circuits in an instrument and the containing case when tested by the application of a continuous-current pressure of not less than 1,000 volts, nor more than 1,500 volts, shall be maintained without rapid fluctuations for a period of one minute, and shall be not less than 5 megohms."

Some definitions precede the specification, with the object of avoiding misunderstanding due to the user and seller not attaching the same meaning to the term employed. No definition is given for "dead-beat," but the preface explains the reason, which is due to the possibility of an instrument being made dead-beat by weakening the control and so involving inaccuracy due to friction.

The price of the specification is 2s. 8d., post free, and it may be procured from any bookseller or direct from the offices of the Committee, 28 Victoria Street, Westminster. It is published for the Committee by Messrs. Crosby Lockwood & Son, 7 Stationers' Hall Court, Ludgate Hill, E.C., and 121A Victoria Street, S.W.

LOCAL NOTES

BARROW-IN-FURNESS: *Electricity Accounts.*—The accounts of the electricity undertaking for the year to March 31st show a revenue of £12,902 compared with £12,428 in the previous year. The total expenditure amounted to £6,286 against £6,440, and after providing for capital charges, there is a deficit of £383 against a deficit of £791 in the previous twelve months. The total number of units sold was 1,057,330, compared with 1,047,776. The number of 8 c.p. lamps or their equivalent connected to the mains is now 78,119, the increase during the year having been 12 per cent. The total costs, exclusive of capital charges, amounted to 1·426d. per unit, the figure for the previous year being 1·474d.

BECKENHAM: *New System of Charging.*—Alderman Dykes' proposed system of free wiring and supplying current for a fixed sum per lamp per annum has been referred to a sub-committee.

BOURNEMOUTH: *Tramway Losses.*—There was a deficiency of £5,416 on the working of the tramways for the year to March 31st, 1909. The Corporation have, in addition, had to pay a sum of £11,800 to meet claims in respect of the tramway accident last year. The unappropriated balance of £25,445, which they had at the beginning of the year, is consequently reduced to £10,390.

Sunday Trams.—A lengthy discussion took place at the Council meeting on Tuesday with regard to the running of Sunday trams, which Mr. J. B. Hamilton, the Leeds Corporation tramway manager, in his report last year, stated would practically turn the present loss into a profit. The motion to run the cars on Sunday, however, was rejected, as was also a proposal to take a poll of the ratepayers.

BRADFORD: *Central Tramcar Depôt.*—Consideration of the scheme outlined in our last issue for the construction of a central tramcar depôt has been postponed for the present.

BRIGHTON: *Railway Workshop Driving.*—The L.B. & S.C. Railway are increasing the number and horse-power of the motors for driving their workshops considerably beyond what was originally contemplated, and instead of the Corporation selling energy to the value of £2,500 per annum, there is every possibility of the sales now reaching £3,500 to £4,000. The General Manager of the company has agreed to recommend his directors to increase the standing charge, payable under the existing agreement, from £750 to £1,000 per annum, subject to the Corporation providing plant and cables of ample capacity to deal with a continuous demand of 600 kilowatts, instead of 500 kilowatts as stipulated for in the original agreement.

DOVER: *Surface-contact Traction.*—The Council have accepted an invitation to inspect the experimental surface-contact tramway of the S.P. Syndicate at Southall, and have instructed the tramways manager and the borough electrical engineer to visit London for this purpose.

Supply to Wireless Telegraph Station.—Negotiations are being carried on with regard to a supply of electricity to the wireless telegraph station on the Western Heights for a period of five years.

EAST HAM: *Tramway Accounts.*—The accounts of the tramways department for the year to March 31st show a deficit of £950.

Electricity Accounts.—The electric lighting accounts for the year to March 31st show a net profit of £1,304. It has been decided to reduce the charge for tramway energy from 1·5d. per unit to 1·3d. per unit.

FINCHLEY: *Street Lighting.*—The Local Government Board have withheld their consent to the Council's application for a loan of £2,200 for street lighting until they are furnished with an estimate of carrying out the proposed lighting by gas. This the Council refuse to do, as they contend it is not the function of the Local Government Board to advise the Council whether gas or electricity should be adopted.

FOLKESTONE: *Surface-contact Traction.*—The Corporation have inspected the S.P. surface-contact system, and have expressed themselves satisfied with it. No arrangements, however, have yet been come to between the Corporation and the National Electric Construction Co., between whom there is an agreement to instal surface-contact tramways. It will be remembered that the company wished to be relieved of this obligation, and offered to instal a combination of the conduit and trolley systems. The proposal was opposed in Parliament, and the company were only granted an extension of time in which to carry out their original agreement.

HOUNSLOW: *Electricity Accounts.*—For the year ending March 31st there was a profit on the electricity undertaking of £293.

LEICESTER: *Electricity Accounts.*—The receipts of the electricity accounts for the half-year amounted to £13,966, while the total expenditure was £5,924. After paying interest on capital £3,791, and sinking fund £3,344, there is a net profit for the half-year of £907. There has been a decrease in receipts of about £1,800.

Technical College Extension.—Professor Silvanus P. Thompson, F.R.S., opened a new wing of the Leicester Technical and Art Schools on Thursday. The extension has cost £14,000.

LONDON: *Bethnal Green: Electric Supply.*—The Council on September 30th debated for two hours in private, proposals with regard to the supply of electricity in the borough. It was finally decided that the question should stand adjourned until after November 9th, when the new Council will come into office.

Hampstead: Electrical Exhibition.—Another exhibition of domestic electrical apparatus has been organised, and will close on Saturday. The exhibition is being held at the Finchley Road Baths.

Islington: Tramways.—The Borough Council, as the road authority, have refused their consent to the proposed tramways through Tollington Park.

Marylebone: Street Lighting.—Up to September 25th, 1,760 of the 1,964 street lamps which the Council resolved to convert to electricity in place of gas had been converted, and the results had been quite satisfactory. As a considerable saving in street light expenditure will be effected in the extension of the system, 165 more street gas lamps are to be converted on the same terms, and authority has been given for further lamps to be taken over as mains are extended.

Apparatus on Hire.—The sum of £500 has been ear-marked from revenue surplus to be gradually applied for the purchase of electrical apparatus to be hired out.

Paddington: Tramways.—The Borough Council has refused its consent to the construction by the London County Council of the proposed tramways from the Marble Arch via Edgware

Digitized by Google

Road to Harrow Road, and from Harrow Road via Edgware Road, Maida Vale, Kilburn High Street, and Shoot-up Hill to Cricklewood. The Borough Council is of the opinion that the North-West London Railway, when constructed, will meet the needs of the locality, in conjunction with various motor omnibus services.

Poplar: Tramways.—Resolutions have been passed by the Council regretting that the London County Council has not arrived at an agreement with the West Ham Corporation for intercommunication on the respective tramway systems. It is stated that one of the conditions upon which the Borough Council agreed to the overhead system from Burdett Road to Bow Road was that there should be inter-running arrangements with West Ham. For three years the West Ham Corporation have been endeavouring to make arrangements with the L.C.C. for a through service, but the last reply received by the West Ham Tramways Manager was to the effect that the L.C.C. Highways Committee had placed the subject in abeyance.

Electrolytic Disinfectant.—In view of the low cost of production of electrolytic disinfectant fluid and its efficiency, it has been decided to duplicate the plant at an estimated cost of £430.

Shoreditch: Electricity Profits.—At the meeting of the Council last week it was stated that the gross profit on the working of the electricity undertaking for the year to March 31st last amounted to £21,335, the net profit, after meeting capital charges being £4,117.

MIDDLESEX: *New Tramways.*—The lines between Acton and Willesden have been opened for traffic, thus linking up the systems of the Middlesex County Council and the London United Tramways Co.

NEWCASTLE-ON-TYNE: *Tramway Finances.*—Owing to the serious dimunition in the number of passengers carried upon the tramways recently, the Tramways Manager has been instructed to take steps for cutting down car-mileage, and for curtailing running expenses. Sir Joseph Baxter Ellis has intimated his unwillingness, owing to advancing years, to allow himself to be re-nominated for the position of chairman of the Tramways Committee for next year.

NEWPORT (MON.): *Electricity Undertaking.*—The Electricity Committee recommend that an expert should be retained to report upon the working of the electricity undertaking.

Tramways.—Inquiries are to be made of the Board of Trade with regard to the use of trailer cars.

PONTYPRIDD: *Electricity Accounts.*—The accounts of the municipal electricity department for the year to March 31st last show a deficit of £1,751 after meeting capital charges. The accumulated loss on the undertaking amounts to £11,186, towards which £7,750 has been contributed by the rates. The total revenue amounted to £9,196, and the expenditure to £5,826.

RAWTENSTALL: *Fall of Tramway Wire.*—A wall bracket to which was suspended one of the span wires of the Corporation tramway system fell last week from the side of the building to which it was attached. Fortunately no one was injured by the fall of the stone block in which the bracket was fastened, but the tramway service was interrupted for a short while.

TORQUAY: *Nuisance from Generating Station.*—Inhabitants in the vicinity of the Corporation generating station have lodged a petition with the Local Government Board complaining of nuisance from smoke and vibration from the works. The Board sent this on to the Corporation for their comments. The Town Clerk states that it was referred to the Electric Light Committee. So far as the smoke was concerned, the Committee had endeavoured to place their contracts for coal with firms supplying smokeless coal, or smokeless so far as it was obtainable, whilst the stokers had strict injunctions to do their best, in firing up, to prevent any possible extra emission of smoke. The Committee had also provided £150 for the installation of a smoke preventive apparatus. The particular installation was not yet decided, but an interview was about to be held with the patentee with a view to early action. As to the vibration, the Council and their officers were quite unaware of the cause for this complaint. It is admitted that the site of the electricity works is not an ideal one, but it is hoped that a scheme for their removal will receive sanction in the course of a few years.

TOTTENHAM: *Lighting of Public Buildings.*—The Council's offices at the Municipal Buildings are to be electrically lighted in place of gas as at present. The North Metropolitan Electric Power Supply Co. have agreed to a flat rate of 4d. per unit, with a discount of 10 per cent., instead of the previously agreed rate of 6d. per unit for the first 100 hours of maximum demand per quarter, and 2d. per unit, less 10 per cent. for all units consumed above this.

WALTHAMSTOW: *Tramway Intercommunication.*—Through running has been arranged between the Walthamstow and Leyton tramway systems, and passengers are now carried direct from Stratford to Epping Forest, the Leyton Council also having an arrangement with the West Ham Corporation for running their cars into Stratford.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BRAY.—The Council require a 50 b.h.p. Diesel engine, and high- and low-tension disconnection boxes. Particulars from the Electrical Engineer, and tenders by October 19th.

BRIDLINGTON.—A loan of £3,000 for a new generating set is to be applied for.

HANDSWORTH.—The Council require a supply of low-tension feeder and distributor cables. Particulars from the electrical engineer, and tenders by October 13th.

KEIGHLEY.—The Corporation invite tenders for two boiler feed pumps; high-tension switchboard and transformers; one 300 kw. motor-generator; mains. Specifications from the Borough Electrical Engineer, Coney Lane, Keighley, and tenders by October 16th.

KENDAL.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £10,000 for the purposes of the electric lighting undertaking.

LONGTON.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £1,740 for electrical extensions.

MANSFIELD.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £3,500, for the purposes of the electrical undertaking. The sum of £2,500 is required for additional mains, £200 for meters. The economiser is also to be enlarged, and a water softening plant installed.

SOUTH AFRICA.—According to the *South African Export Gazette*, three generators of 2,000-kw. capacity are about to be ordered for the new Farrar-Anglo-French power station. Orders will shortly be placed for a number of electric motors for the Rand Water Board. The Monomotapa Concessions, Ltd., will be in the market in the near future for a large hydro-electrical plant.

SPALDING.—The installation of an electricity works is under consideration by the Council, a special committee having been appointed to deal with the matter.

WORTHING.—Tenders are invited for vulcanised bitumen sheathed concentric and triple-concentric cables, for drawing into stoneware conduits. Specifications and particulars from the Resident Electrical Engineer, Electricity Works, High Street, Worthing, and tenders to the Town Clerk by October 11th.

Miscellaneous

BOLTON.—The Corporation's Tramway Bill having received Royal Assent, it has been resolved that the construction of the tramways to Darcy Lever be proceeded with at once.

BRUMBY AND FRODINGHAM.—The Council invite tenders for the electric lighting of their streets. Direct current at 220 volts is available, and it is proposed to instal 55 lamps of 50 c.p. each. Particulars from the Surveyor, and tenders by October 16th.

OLDHAM.—The Tramways Manager has informed the Tramways Committee that it will shortly be necessary to spend a considerable sum of money on the permanent way.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—St. Giles's Church, Cripplegate, is to be wired for electric lighting.

E.—School, cookery centre, and caretaker's apartments, Vicarage Lane, East Ham. Architect, R. L. Curtis, 5 West Hill, Hornsey, N.

N.—School, Crowland Road, Tottenham, N. (£20,553). Builder, J. Stewart, 174 West Green Road, Tottenham, N.

S.E.—Shirt factory, Wood Street, Woolwich, S.E. J. Randall, 89 Chancery Lane, W.C.

PROVINCES.

ABERDEEN.—Church, Great Western Road. Architect, J. Milne, Aberdeen.

ABERTYSSWG.—Cottage hospital (£2,000). Architect, T. Mathew, Abertysswg.

BIRMINGHAM.—Fire station. Architect, F. Harrison, 109 Colmore Row, Birmingham.

Police station. Architect, T. Smith, Mosley Road, Birmingham.

BRISTOL.—Club premises. Architect, H. Smith, 23 Clare Street, Bristol.

Digitized by Google

Extensions, Clifton College (£14,000). Builders, Cowlin & Son, Stratton Street, Bristol.

DUDLEY.—Additions to schools, Cinder Bank and Nelson Road for the Corporation.

EASTBOURNE.—Alterations to railway station and erection of new offices. Surveyor of the L.B. & S.C.R. Co.

Alterations and additions, London & Provincial Bank, Ltd. (£2,200). Architect, Bertram Earp, Eastbourne.

HARTLEPOOL.—Extensions, Henry Smith School (£10,500). Architect, J. Garry, West Hartlepool. Builder, R. Marshall, Hartlepool.

LEYTON.—Tenders are to be invited for the electric lighting of Canterbury Road school.

LIVERPOOL.—Estimates of the cost of wiring the Lady Chapel at the Cathedral for electric lighting are to be prepared.

MANCHESTER.—The Baths and Washhouses Committee invite tenders for the wiring and complete installation of electric lighting at the Cheetham Baths and Public Hall. Particulars from the City Architect, and tenders by October 12th.

NOTTINGHAM.—Swimming baths, Meadows Cricket Ground (£9,000). F. B. Lewis, City Architect, Nottingham City Council.

Church. The Vicar of Carrington Church, Nottingham.

Extensions to Carrington School (£6,450). W. J. Abel, Secretary Education Committee, Nottingham.

ROMFORD.—School, Heath Park. Architect, F. Whitmore, Duke Street, Chelmsford.

SALFORD.—Operating theatre at Royal Hospital, Chapel Street.

SOUTHEND.—Rink, Warrior Square. Rinkeries, Ltd., Southend-on-Sea.

WHITBY.—Secondary school. Architect, Thompson & Bristow, Westminster Chambers, S.W.

WILTSHIRE.—Stratton Workhouse is to be fitted for electric lighting.

WOLVERHAMPTON.—Salvation Army Halls. Officer, 32 Dartmouth Street, Wolverhampton.

Additions, school of art. Builder, Lindsey Jones, Darlington Street, Wolverhampton.

URBAN DISTRICT OF BRAY.

ELECTRICITY WORKS.

NOTICE is hereby given that the Bray Urban District Council will at their meeting to be held in the Town Hall, Bray, on Tuesday, 19th October, 1909, at 10 a.m., be prepared to receive and consider tenders for the following :—

Section I. 50 B.H.P. Diesel Oil Engines.
Section II. High- and Low-Tension Disconnecting Boxes, etc.

Plans and specifications may be obtained from Mr. W. J. U. Sowter, M.I.E.E., Electrical Engineer to the Council, Electricity Works, Bray, on payment of a deposit of £1 1s. for each section, and such deposit shall be returned on receipt of *bona fide* tenders.

The Council do not bind themselves to accept the lowest or any tender.

Sealed tenders marked "Tender for Diesel Engine" or "Tender for Disconnecting Boxes," as case may be, to reach undersigned not later than 10 a.m., on date mentioned above.

By Order,

Town Hall, Bray, 5th October, 1909.

P. MacDONNELL, *Clerk to the Counc*

TENDERS RECEIVED AND ACCEPTED

ABERDEEN.—The tender of J. Jackson has been accepted for the wiring of St. Clement's Church at £60.

BELFAST.—The tender of Messrs. Imeson, Finch & Co. has been accepted for the supply of trolley wire.

The tender of Messrs. J. Dowling & Sons, at £460, has been accepted for electric wiring, &c., of the asylum.

BEXHILL.—The tender of Messrs. Siemens Bros. & Co., Ltd., has been accepted for the supply of 1,000 yards of cable at £121.

BLACKPOOL.—The tender of G. Morrison, of Blackpool, has been accepted for the electric wiring of the Lancashire & Yorkshire Railway Company's employees' home at the Central Drive, Blackpool.

BRIGHTON.—The Electric Lighting Committee recommend the acceptance of the tender of Messrs. Siemens Bros. & Co., Ltd., for cable in connection with the supply to the L.B. & S.C. Railway workshops at £2,380.

BRISTOL.—The Corporation have accepted the following tenders :—Electrical Co., Ltd., A.C. meters, £762 8s.; General Electric Co., Ltd., carbons—twelve months ending April 30th, 1910, £366 12s. 4d.; Siemens Bros.' Dynamo Works, Ltd., arc lamp globes, £31 2s. 6d.

CANADA.—We recently mentioned some tenders that were given out by the Winnipeg Municipality in connection with the new power station at Point du Bois. The *Electrical World* (New York) gives the following further list of tenders which have been accepted :—Turbines, Jens Orten, Böving & Co., London, $97,150, including erection; generators and exciters, Vickers, Sons & Maxim, Ltd., Sheffield, $93,000, including erection; transformers, switching and protective apparatus, Canadian Westinghouse Co., Ltd., Hamilton, Ont., $150,800, including spare parts; light, heat and power system, generating system, Canadian General Electric Co., Toronto, $11,600; travelling cranes, Canadian Fairbanks Co., Ltd., Winnipeg (Niles-Bement-Pond Co.), $14,900, including estimated cost of erection; auxiliary apparatus, Canada Foundry Co., Ltd., Toronto, $27,520; Canadian Fairbanks Co., Ltd., Winnipeg, $6,901, and allowance for contingencies and spare parts, $25,049.

CHESTER.—The tender of the Sloan Electrical Co., at £116, has been accepted for the supply of carbons during the ensuing twelve months.

DUNDEE.—The British Electric Plant Co., Ltd., of Alloa, N.B., is supplying a motor-generator set to the new Dundee Technical College, and is also supplying two motor-generators for the West Graving Dock.

GRIMSBY.—The Council have accepted the tender of Cragg & Nephew, Doncaster, for twelve months' supply of steam coal for the electricity undertaking at 5s. 11d. per ton, delivered at the works. They have further accepted the tender of Johnson & Phillips, Ltd., for two years' supply of cables at £757.

INGLETON.—The tender of the Ingleton Electric Light Co., at £40, has been accepted for public lighting during the ensuing twelve months.

JAPAN.—The Japanese Government have awarded the contract for twelve 50-ton electric locomotives to Messrs. Siemens & Halske. Both the Westinghouse and the General Electric Companies of America submitted tenders.

LONDON: *Fulham.*—The Council have accepted the tender of the Electrical Co., Ltd., for 150 meters in various sizes for a total of £202 5s.

Hackney.—A 5-kw. C.M.B. auto-converter, designed for a primary pressure of 480 volts, and a secondary pressure of 100 volts, is to be obtained at an estimated cost of £57, in connection with an electric standby at the Baths.

Marylebone.—The Council have accepted the tender of Messrs. C. A. Parsons & Co., at £162 10s., for putting carbon brushes on three turbo-generators. As a check on the coal consumption, two additional flue-gas recorders are to be obtained from the Auto-Recorder Co. at £60 less 5 per cent.

St. Pancras.—The Council received the following tenders for the rewinding of the 500-kw. armature at the Regent's Park station :—White, Jacoby & Co., Ltd. (accepted), £130; Siemens Bros. Dynamo Works, Ltd., £214; the Westminster Engineering Co., Ltd., £214.

Woolwich.—The Town Council received the following tenders for 580 yards of 4-core 0·05 cable :—W. T. Henley's Telegraph Works Co., Ltd. (accepted), £152; Siemens Bros., Ltd., £154; Callender's Cable & Construction Co., Ltd., £158. For 310 yards of 0·2 and 250 yards of 0·05 cable, the following tenders were received :—Siemens Bros., Ltd., £192; alternative (accepted), £46 14s.; W. T. Henley's Telegraph Works Co., Ltd., £194; alternative, £47; Callender's Cable & Construction Co., Ltd., £196; alternative, £48.

LUTON.—The tender of Messrs. P. T. King, at £57 10s., has been accepted for the electric wiring, &c., of the new buildings of the Guardians.

SALFORD.—The Council have accepted the tender of the Tudor Accumulator Co., Ltd., for the maintenance of the battery supplied by them (in accordance with their tender accepted in July last) for a period of ten years, with the option of extension, at £530 per annum.

SOUTH AFRICA.—Messrs. Gent & Co. have shipped a number of electric clocks to the order of the Cape Government.

STOKE.—The Guardians have accepted the tender of Electromotors, Ltd., for an 11-h.p. motor and starter to drive the laundry machinery at the cottage homes, at £57.

YORK.—The Corporation have accepted the tender of Messrs. Dick, Kerr & Co., Ltd., for the extension of the electricity mains along the routes of the light railways now under construction. The tender of Messrs. Cox-Walkers, Ltd., has been accepted for a traction switchboard at £383.

COMPANIES' MEETINGS AND REPORTS

PUEBLA TRAMWAY LIGHT & POWER CO.—The report states that the Board have secured the control of the San Agustin Company as from July 1st, 1909, on satisfactory terms, and that they expect a material increase of revenue in consequence. The results for the six months to June 30th, 1909, show a marked improvement over those of the previous period, the net profits for that period amounting to approximately £21,500 (nearly equal to the profits earned in the year 1908), and thus the bond interest for the same period, £21,891, is practically covered. The directors have decided to proceed immediately with the partial development of the Tuxpango Falls (30,000 h.p.).

MASCHINENFABRIK OERLIKON.—The net profit for the year 1908-9 amounts to 446,692 frs., which, after deducting 120,000 frs. for reserve fund, enables a dividend of 4 per cent.

Digitized by Google

to be paid, as in the previous year. The turnover was not quite so great as that of the previous year, but the works are now busier than they were in the corresponding period last year.

WILLANS & ROBINSON.—The half-yearly meeting was held on Tuesday in London, when the report and accounts given in our last issue were adopted. Mr. J. C. Peache, the managing director, presided, and stated that there was no doubt for the present, and for the immediate future, they had to face a continued scarcity of work. However, notwithstanding the poor result of the past half-year, the company's position was a sound one. They had hopes that the sale of the Queen's Ferry Works would result from negotiations now in progress.

MISCELLANEOUS CITY NOTES

EDGAR ALLEN & CO.—An interim dividend has been declared on the 5 per cent. cumulative preference shares for the half-year to September 30th.

PARA ELECTRIC RAILWAYS & LIGHTING CO.—The dividend on the 6 per cent. cumulative preference shares for the half-year to May 31st is announced.

BRISBANE ELECTRIC TRAMWAYS INVESTMENT CO.—An interim dividend of 3s. 6d. per share on the ordinary shares is announced.

ANGLO-AMERICAN TELEGRAPH CO.—The directors, after placing £5,000 to credit of renewal fund, declare an interim dividend for the quarter ended September 30th of 15s. per cent. on the ordinary stock, and of £1 10s. per cent. on the preferred stock, less income-tax, payable on November 1st.

EASTERN TELEGRAPH CO.—A quarterly dividend of 1¼ per cent. is announced on the ordinary shares, free of tax.

NEW YORK TELEPHONE CO.—Applications have been invited this week in London for subscriptions to an issue of £5,000,000 4½ **per cent. bonds,** the list closing to-day (Thursday). The New York Telephone Co. is a consolidation of all the "Bell" telephone companies in the State of New York.

EBRO LIGHT & POWER CO.—A prospectus will shortly be issued by this company, which has for its objects the supply of electric light and power to a number of towns in North-East Spain, including Barcelona and Tarragona. The share capital is £3,500,000, of which £1,500,000 is 6 per cent. cumulative preference shares, and £2,000,000 ordinary shares. The impending issue consists of £1,250,000 preference shares. A report by Mr. H. F. Parshall accompanies the prospectus.

CALCUTTA TRAMWAYS CO.—An interim dividend of 2s. per share on the ordinary shares, free of tax, is announced in respect of the June half-year.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 to £60 10s. per ton (last week, £60 7s. 6d. to £60 17s. 6d.).

THE ELECTROMOTOR & DYNAMO CO.—We are informed that the business of this company (15 Gray's Inn Road) has been taken over by Messrs. J. & H. Grevener, who are now in a position to supply motor generators, transformers, and controllers of the highest quality, as well as their well-known Arcoflame lamps. The new branch of their business is still being conducted under the supervision of the late manager of the Electromotor & Dynamo Co., which company is, of course, in no way connected with the well-known Lancashire firm of Electromotors, Ltd.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A first and final dividend of 4s. 3½d. in the £ is announced in the bankruptcy of L. W. de Grave, electrical engineer, 92 Kedleston Road, Derby.

RECENT D.P. BATTERY ORDERS.—Amongst the orders which, we are informed, the D.P. Battery Co., Ltd., received last week, they have been commissioned by H.I.H. Empress Eugenie to instal a storage battery of their LS 13 type at Farnborough Hill, and by the Crown Agents for the Colonies to supply a battery of 118 L 15 type cells for the Bahamas. They have also been favoured with orders for sixteen of their specially designed 25 volt batteries for private residences.

CHANGE OF ADDRESS.—The Holophane Glass Co. have removed from 146A Queen Victoria Street, London, E.C., to 12 Carteret Street, Westminster, London, S.W.

"METFIL" LAMPS.—The following unsolicited testimonial has been received by the Edison & Swan United Electric Light Co., Ltd., of 36 Queen Street, E.C., from one of their customers:- September 24th, 1909: We have to-day despatched to you for your inspection one of your 32-c.p. 100-volt Metfil lamps. This has been in use for 5,860 hours, and has only just burned out.

ELECTRIC ORGAN-BLOWING.—The Adnil Electric Co., Ltd. (Marples, Leach & Co., Ltd.), who specialise in electric blowing installations for church and public hall organs, have recently been favoured with a number of important orders, amongst which we mention the following:—St. Anthony's Catholic Church, Forest Gate; Brunswick United Methodist Church, Burnley; St. Chad's Church, Stafford; Parish Church, Colne, Lancs; St. Edmund's Church, Roundhay, Leeds; St. George's Schools, Ascot; St. Mark's, Surbiton; The Chapel, Welbeck Abbey, for his Grace the Duke of Portland; Earl of Cadogan's Church, Culford; the residence of R. W. Hawkey, Esq., Chiswick; Christ Church, Chester; Tonbridge Schools, Tonbridge, Kent; chamber organ at Messrs. Chappell's warehouse, New Bond Street; St. Matthew's Church, Southsea. In the majority of these cases the wiring installations are being carried out by the local contractors. Marples patent system of regulation is employed in all the direct-current installations, and the "Adnil" single-phase self-starting alternating-current motor in the alternating-current installations. An interesting pamphlet has been prepared by the firm, copies of which will be sent on application.

CATALOGUES WANTED.—Owing to a fire, Messrs. Sanford & Co., Monterey, N.E. Mexico, have had their stock of catalogues completely destroyed. Manufacturers of electrical equipment of all kinds are requested to send catalogues and price lists.

APPOINTMENTS AND PERSONAL NOTES

The Bristol Corporation have confirmed the appointment of Mr. A. E. Wilson, at present distribution superintendent, as chief assistant engineer in the place of Mr. H. H. Couzens, now chief electrical engineer and manager to the West Ham Corporation.

The late Mr. Hugh Erat Harrison, Principal of Faraday House, left estate of the value of £17,012.

York Tramways Committee recommend the appointment of Mr. J. W. Hame, City Electrical Engineer, as General Manager of the electric tramways now under construction. The remuneration for the position is to be fixed later.

Mr. A. Whalley, M.I.E.E., is retiring from the British Insulated & Helsby Cables, Ltd., to commence a consulting practice, from November 1st, at 27 Chancery Lane, London, E.C. (c/o Knox, Hassal, Dodd & Co.), and at 19 Croxteth Grove, Liverpool. During twenty-three years with the Telegraph Manufacturing Co., Helsby, and with the British Insulated & Helsby Cables, Ltd., he has been chief engineer at Helsby and manager and engineer at Liverpool respectively, and been responsible for the design and manufacture of every description of insulated wire and cable for lighting, power, traction, telephony, &c. He has carried out the equipment of the London and other large telephone trunk exchanges for the Post Office during the last six years, besides common battery exchanges. For twenty years, switchboards, &c., have been supplied under his control to the National Telephone Co.

Birmingham and District Electric Club.—The opening meeting of the session will be held at the Colonnade Hotel, New Street, Birmingham, on Saturday next, at 7 p.m., when a smoking concert will take place.

Institution of Mining Electrical Engineers.—Mr. W. Maurice presided over a meeting of the Institution of Mining Electrical Engineers at the Royal Victoria Hotel, Sheffield, on Saturday last, when representatives were present from all the localities for which sectional committees have been formed. In an address Mr. Maurice stated that such progress had been made since they last met that the Council had decided to have the Institution incorporated under the Companies Act. Articles of association had been drawn up, and provision had been made for the formation of a benevolent branch at a later stage, if this was deemed advisable. As in other institutions of a similar character, there would be several classes of members, and honorary membership would be granted to gentlemen who had distinguished themselves by literary or scientific achievements, or had given such assistance to the Institution that the members desired to do honour to them. Arrangements would also be made for receiving reports from abroad on mining matters, and reports from Germany and Austria had already been provided for. Diplomas would be granted to those members deserving them as evidence of competency. After the articles of association had been accepted by the Board of Trade, probably by the end of October, arrangements would be made for the inaugural meeting of the Institution. The Home Secretary had stated that the constitution of the committee, which was shortly to be appointed by the Home Office to consider the existing regulations regarding the use of electricity in mines, would not allow of representatives of the Institution upon it. He would, however, be glad to receive information and suggestions, and it would be the business of the Institution to proceed in this way. A week or two ago some considerable stir was created in one of the principal mining centres of this country by a section of the mining community who did not regard electricity as a safe medium for use in coal mines. The Council felt that that action had had a prejudicial effect in regard to electricity, and they had decided to inquire into and report upon the causes of mining accidents, and the means to be adopted to prevent them. A discussion took place with regard to the place where the inaugural meeting of the Association should be held, London and Manchester receiving the greatest support. A vote is to be taken as to which of these two places shall be decided upon.

CORRESPONDENCE

Correspondence is invited on all subjects of interest to our readers. The Editor is willing to insert letters over a nom de plume, *but Correspondents should send their names and addresses in all cases. Letters should be addressed,* "The Editor, Electrical Egineering," 203-206 Temple Chambers, Temple Avenue, London, E.C., *and should reach this office by first post on Tuesday morning. Correspondents are requested to write on one side of the paper only.*

THE WELSBACH COMPANY AND THE METAL FILAMENT LAMP.

To the Editor of Electrical Engineering.

Sir,—My attention has been drawn to the article in your issue of the 23rd inst. under this heading, in which you invite a further announcement from the Welsbach Company, and my reply is that the metallic filament lamps of the Welsbach Incandescent Gas Light Co., Ltd., are what they purport to be, neither more nor less.

If anyone feels himself aggrieved by the company's action, he has his remedy, and the company's solicitors, who are Messrs. Michael Abrahams, Sons & Co., of 5 Tokenhouse Yard, E.C., have full instructions to deal with such an eventuality.

Yours faithfully,
For the Welsbach Incandescent Gas Light Co., Ltd.,
344-354 Grays Inn Road, Lee Fletcher,
London, W.C., Managing Director.
Sept. 29th, 1909.

BONDING AND EARTHING.

To the Editor of Electrical Engineering.

Sir,—The recent correspondence on the earthing of mains' systems suggests to me that some of your readers might perhaps be interested in pursuing a side issue of this matter, viz., the effect on a supply system of internal wiring with continuously earthed return. I am referring more particularly to the "Metacase" systems which have recently been advertised, and one form of which, at least—the "Stannos" system—appears to be achieving some popularity.

By using the metal case "Stannos" wiring with the casing as a return, a very neat and inexpensive method of wiring becomes available on alternating-current systems, provided that a double-wound transformer is employed; the only drawback in the writer's opinion to this being that the installation is committed for all time to the use of a transformer, which, in the progress of the metallic lamp, may, in the near future, become unnecessary or undesirable. Further, such an installation calls for rather close inspection by the supply authority, in order to ensure that the "Stannos" material is not used in extensions, without the double-wound transformer to isolate its outer sheathing from the mains system.

In the writer's opinion, it is desirable that the consumers should be made aware of the necessity of always having a transformer, to isolate them from the supply system when the metal-cased installation is put in, as otherwise some difficulty and annoyance may be experienced in the future when it is discovered that the system of wiring used, although cheap in the first instance, has soon fallen out of date. Similar remarks would appear to apply to the electric geyser recently described in your columns, which, although only in use for short intervals at a time, apparently earths the supply mains within the building during the time that water is flowing through it.

Possibly those responsible for pushing these inventions may have some experience in this connection which would be of interest to many engineers.

Yours truly,
September 28th, 1909. J. W. B.

NATIONAL INSTITUTION OF APPRENTICESHIP.

To the Editor of Electrical Engineering.

Sir,—Will you allow me through your columns to call attention to the valuable work which is being done by the National Institution of Apprenticeship, 39 York Place, Baker Street, in apprenticing boys and girls to trades in which skill is required, and to appeal to the public for contributions to enable the Council to continue to carry on and extend that important national work. Its value cannot be easily over-estimated, especially as it tends to diminish the number of the unemployed who are nearly all unskilled. The Institution is philanthropic and unsectarian, and is under the patronage of her Royal Highness the Princess Christian and his Grace the Duke of Devonshire, and is administered by a council and several committees.

The Council's report for 1908 shows that the Institution has great experience, and exercises a careful discrimination in the selection of trades and in the general management. The effective manner in which the arrangements for apprenticeships are conducted and the excellent results achieved were demonstrated at the largely attended meeting recently held at the Mansion House, at which I presided, when about 500 apprentices under the charge of the Institution were present, and 172 of them received prizes and certificates, which were distributed by Lord Avebury. The Institution has indentured over 630 apprentices to good masters carrying on skilled trades, and those apprenticeships are supervised by the Council.

The number of boys and girls applying to be apprenticed is continually increasing, and now exceeds 60 per week, and at the present time a large number of boys who have served satisfactorily their probation are compelled to wait until the money is forthcoming to pay the premiums. For such purpose it is estimated that a sum of £13,000 will be required during the next twelve months, and the audited accounts show that the funds are now practically exhausted.

I shall be pleased to receive contributions on behalf of this excellent Institution, or they may be sent to the treasurer, the Right Hon. Lord Avebury, at 17 Lombard Street, London, E.C., or to the hon. sec., Mr. J. S. Ballin, 5 Clarence Terrace, Regent's Park, N.W.

I am, Sir,
Yours faithfully,
Mansion House, G. Wyatt Truscott,
September 30th, 1909. *Lord Mayor.*

*** Will "Pitman," of Gateshead, kindly send his name and address.

REVIEWS OF BOOKS

The Theory of Electric Cables and Networks. By Alexander Russell. 269 pp., 8½ in. by 5½ in., 71 illustrations. (London: Archibald Constable & Co.) Price 8s.

The reviewer of this book has been asked on more than one occasion if any of the various technical books dealing with electric cables will give sufficient information that will enable an engineer so to design his high-tension feeders that in ordinary circumstances there should be no risk of undue potentials arising through resonance effects. The practical application of the theory of resonance phenomena is a subject that has been much neglected. Although it is impossible to predetermine and to guard against every one of the conditions that might cause an inductive rise in pressure sufficient to damage the cables, generators, or transformers of a high-tension system, yet an engineer may not be satisfied to leave the matter entirely to chance, and to trust entirely to his spark gaps and his good luck. In spite of the title of this work, however, Dr .Alexander Russell has not thought fit to deal with this branch of the subject; he has merely referred the reader in the preface to his previous book on the theory of alternating currents for the consideration of questions in connection with the electrostatic capacity and the inductance of cables. In the present work, it is true, there is a chapter on "Electrical Safety Valves," but in this only the merest hint is given how the circuits should be designed so that the spark gaps should be called into requisition as infrequently as possible.

In other respects the distributing engineer will find

Digitized by Google

much that is useful to him in Dr. Russell's book; in fact, it may be recommended even more to the practical man than to the student. The engineer with experience to guide him will better be able to read the various chapters with discrimination. For instance, in the chapter on "Insulativity," he will forget this ugly substitute for "specific insulation," but will accept without hesitation, the formula showing the variation of insulation resistance with thickness of dielectric. He will realise the utility of the "guard wire" as a useful addition to the older connections for insulation testing; but he will know that for practical test-room purposes he must also add to the author's otherwise correct diagram of connections a short-circuiting key across the galvanometer to prevent the charging current from damaging the galvanometer when the battery key is first depressed. On a later page in the same chapter he will welcome the information that Para rubber is obtained from a euphorbiaceous tree as a pleasant addition to his general knowledge; but he will remain unaffected by the statement that "the best material for insulating cables is rubber," and by the omission of the items "lead-covered" or "paper" from the index at the end of the book.

Dr. Russell shows throughout his work that he possesses an intimate acquaintance with the literature of the subject; he has the happy knack of picking out, borrowing, and often improving on what is best in the various books and papers that have been published, and his complete bibliography is in itself one of the most valuable parts of the book.

Practical Alternating Currents and Alternating-Current Testing. By Charles F. Smith. (Third edition.) 455 pp. 8½ ins. by 5½ ins. 236 illustrations. (Manchester: The Scientific Publishing Co.) 6s. net.

We cordially recommend this, the third edition of an excellent text-book, which has been thoroughly revised and brought up to date. Students will find the work of great value, as it contains all the necessary information to give the reader a clear practical insight into the principles of alternating-current working. The explanations are technically sound and of strict scientific accuracy, without being too academic in nature. Only an elementary knowledge of continuous-current working is assumed, and the use of the higher mathematics is avoided, except in one or two cases.

The author supplements his explanation of each phenomenon or apparatus with a numerical example, and the reader is thus constantly confronted with the practical utility of his studies. Most of these examples are put in the form of actual experiments, which are described in detail, and which help to convey exact and concrete ideas, even if the reader is unable actually to carry out the measurements described. No one will deny, however, that the actual handling and testing of apparatus and machinery is essential to a true appreciation of the phenomena involved, and, indeed, it is in the laboratory and the test room that this volume should prove of particular value.

After dealing with the general principles of alternating currents, the effects of capacity and induction, and the measurement of power, the author devotes a long chapter to the transformer. This includes descriptions, actual figures, and curves of typical tests on transformers, including the Hopkinson and other important tests, and concludes with a few pages on the auto-transformer. The principle of the latter is clearly explained, and its economy as compared with a double winding transformer illustrated by an example of a one-kw. transformer for supplying low-voltage metal filament lamps off 200-volt mains. The following chapter deals with the characteristics of alternators, the various tests being fully described, with numerical results and curves of actual experiments in each case. Chapters on the synchronous motor, the polyphase circuit, the rotary converter, and the motor converter, are followed by a clear description of the working of the induction motor and of the methods of testing this machine. This last chapter has been largely re-written since the last edition, and, as in the case of the preceding chapters, includes the results and curves of actual tests.

An introduction to the complex problems connected with the operation of A.-C. commutator motors is given in the chapter on single-phase motors, which appears for the first time in this edition. The concluding chapter includes a description of the operation of the oscillograph, and a method of analysing wave forms into their component harmonics. This last item could, we think, have been well replaced by brief references to the various effects of harmonics in alternating-current circuits, and particularly the effects of third harmonics in the delta-connected windings of three-phase machines, or in circuits with the neutrals of the star-connected generators earthed. The treatment throughout the book is necessarily based on the assumption of sinusoidal wave-forms of E.M.F. and current, but some reference to the practical effects of a departure from a sine wave would be a useful addition.

No attempt is made, of course, to give any details of the construction of the apparatus and machines concerned, and the 236 figures are all either diagrams of connections, curves, or vector diagrams, of which last considerable use is made.

Metric Tables. By Sir Guilford L. Molesworth. Fourth Edition. 95 pp. 3 in. by 4¾ in. (London: E. & F. N. Spon, Ltd.) 2s.

Most engineers are adepts in the use of the slide rule, and by remembering a few of the most important relations between the different systems of weights and measures, any equivalent can be obtained as readily as by referring to such tables as this little pocket-book contains. On the other hand, for those who do not use a slide-rule, or who desire to work to a higher degree of accuracy, tables of this nature are of great value, and the present little volume, which contains nearly one hundred three-figure tables of equivalent English and metrical values for measurements, weights, &c., is an excellent example of this class of work. The tables include equivalent values in temperature, energy, pressure, speed, and money units of the two systems, and a useful summary of the relations between the various units is given, as well as a complete index to the tables. In the preface, Sir Guilford Molesworth puts in a plea for the general adoption of the Metric system in this country, pointing out how fast it is gaining in favour in all other parts of the world, including the United States of America and Japan.

English Prices and German Equivalents. By St. Koczorowski. 95 pp. 3¼ in. by 4 in. (London: E. & F. N. Spon.) Price 1s.

The little pocket-book before us should be found useful to firms doing export trade with Germany. It is on the same lines as the previous compilations dealing with French and Russian prices, issued by the same publishers. It consists of conveniently arranged tables calculated at seven rates of exchange in marks per kilogramme, giving equivalent prices in English currency per lb. and per ton.

Electrical Circuits and Diagrams. Part II. By N. H. Schneider. 73 pp. 5 in. by 7¼ in. 69 illustrations. (London: E. and F. N. Spon.) 1s. 6d. net.

This book comprises a collection of sixty-nine diagrams of connections for typical electrical machines and apparatus, including synchronisers, single-phase motors, mercury-arc rectifiers, and booster transformers, besides the more usual apparatus. Opposite each diagram are a few words of explanation.

CONDUIT EXPLOSION IN DERBY

A SERIOUS explosion of gas in the cable conduits in the neighbourhood of St. Peter's Street, Derby, took place last Wednesday night. It appears that there was an extensive leakage of gas which the gas company had been unable to locate, and the gas, which had accumulated in an underground transformer chamber about 10 ft. square near the Queen's Monument, became ignited by a spark from a switch controlling some arc lamps. The attendant who had pulled out the switch was knocked down by the explosion and somewhat injured. He states that he did not notice a smell of gas, and that the manhole above him, 3 ft. square, was open. Manhole covers were blown off at a number of points even at a considerable distance, and paving stones were upheaved; a few persons were injured, and many had narrow escapes. We understand that the primary cause was a broken gas-pipe some 200 yards from the explosion, and Mr. T. P. Wilmshurst, Borough Electrical Engineer, remarks that the gas company did not inform the Electricity Department of the leak. Such notice is usually given in serious cases, and the manhole covers are then lifted and assistance given. All these pipes lead into sub-stations which are ventilated. It should be added that no damage was done to the cables, nor was the supply in any way interrupted.

Electric Traction in Venezuela.—A British consular report, referring to the recent introduction of electric traction on six miles of the Central Railway Co.'s system, states that the line is being extended to Santa Lucia, which place may become the transport centre of the Tuy River district.

THE IRON AND STEEL INSTITUTE

DURING the proceedings of the first day of the meeting of the Iron and Steel Institute, which was held during last week in London, a Paper by E. J. Ljungberg (Falun, Sweden), was read on:—

Production of Iron and Steel by the Electric Smelting Process.

At the beginning of his Paper, the author referred to a 2-ton Kjellin induction furnace at Gysinge, one of the works belonging to the Stora Kopparbergs Bergslag. At present not more than about one ton at a time is tapped, and the continuous current used in this furnace represents about 200 kw., and the output in 300 days amounts to about 1,200 tons of ingots using 50 per cent. pig and 50 per cent. scrap. No other pig iron is used except the famous Dannemore brand, extremely low in phosphorus and sulphur, and the product is a high carbon tool steel, possessing some superiority over steel made by the ordinary melting processes.

For a country like Sweden, possessing practically no coal-mines but numerous waterfalls, the manufacture of iron and steel direct from ore by the agency of the electric current is of much more interest than the melting of pig and scrap to make steel. At the works at Domnarfvet extensive and costly trials have, therefore, been made in the direct reduction of ore during this and the past few years.

The latest furnace used, constructed by Messrs. Grönvall & Lindblad (the Electro Metal Co.), Ludvika, is similar to a common blast-furnace, but with three electrodes fed by three-phase alternating current at about 40 volts, 60 cycles, and 9,500 amperes, averaging 674 h.p., instead of tuyeres; 28 tons of iron have been produced in 1,903 hours with a consumption of 422 tons of ore, 24 tons of lime, 41 tons of coke, and 58 tons of charcoal; 891,623 kw. hours was the total energy absorbed, and 6·5 tons of electrodes were used.

No air whatever is used in the process, and the gases are produced from the carbon in the charcoal and coke and the oxygen in the ores ($FeO+C=Fe+CO$). Either charcoal or coke may be used, but the consumption of fuel will be practically the same in either case.

The furnace consists of a lower portion or smelting chamber, corresponding to the hearth of a blast-furnace, and a top section or shaft. The latter is supported on columns, which prevent any weight from bearing on the arch of the smelting chamber. The latter is so proportioned as to provide a considerable amount of free space between the charge and the arched roof through which the carbon electrodes project into the charge. The brickwork is thus protected against any very high temperature, and remains a non-conductor of electricity. This is an important feature of this furnace, since experiment has shown that if the electrodes enter the chamber at the point where the charge touches the walls, a very high temperature is generated at this point; the brickwork is destroyed and becomes a conductor of electricity, giving rise to a more or less complete short-circuit. The brickwork may be further cooled by means of a blast of cool gas taken from the top of the furnace and blown in round the electrodes with a fan, no heat being lost by this proceeding.

The ore and fuel are crushed to a suitable size, and are fed into the top of the furnace through the bell hopper in the usual way, the ore being partially reduced by the carbon monoxide rising through the charge. The latter spreads out in the smelting chamber as shown, and the reduction is there completed. Since the electrodes project well into the charge, the highest temperature occurs in the centre of the latter, and the brickwork is thus kept cool compared with the walls of an ordinary blast-furnace.

The only speaker in the discussion was Mr. P. R. Cobb, who said that furnaces of this type had been tried with satisfactory results at Sault-Ste. Marie, in Canada, where three would be running regularly about the middle of next year.

A Paper was also read at the same meeting by Mr. C. A. Ablett on:—

The Determination of the Economy of Reversing Rolling-Mills.

In his preliminary remarks, the author stated that since the last autumn meeting of the Iron and Steel Institute, five steel-works have decided to adopt electrically driven reversing rolling-mills, making in all over 20 firms who have come to this decision, and 12 such plants are at work in different parts of the world, one at least being installed to replace an engine less than 10 years old which was in good condition. The reasons influencing this decision may be briefly summarised as follows: Greater economy in fuel consumption; larger output from plant; reduced running costs, *i.e.*, reduction in cost of repairs, attendance, oil, &c.; greater convenience and reduction of management expenses due to centralisation of power supply; and the fact that the great economy of the electrical plant is maintained throughout the life of the plant, and does not diminish as the parts wear.

The capital cost of an electrically driven reversing-mill is greater than that of a steam-driven mill driven by a plain two-cylinder engine, but in the last two years the experience gained in setting a number of such plants to work has enabled the capital cost to be very materially reduced. Further reductions in the capital cost are scarcely possible unless some entirely new method of reversing-mill driving is evolved in place of the Ilgner system, which has been employed exclusively up to the present, and the present state of electrical knowledge does not offer much prospect of this. In a very large number of cases the economies which could be effected by the adoption of electric driving are found to amply justify the increased capital expenditure. At the present time, the question of saving in fuel consumption appeals to most steelmakers as the chief inducement offered by electrical driving, as the possibilities in the direction of greater output are not fully recognised, there being as yet no published figures relating to this.

Tests are frequently made to determine the economy of a reversing-mill engine, either by indicating the engine and estimating the steam consumption per indicated horse-power from some of the larger diagrams, or, where boilers can be isolated, by measuring either the feed water or the coal burnt for a considerable period, and keeping a record of the tonnage of steel rolled over that period, so that the result is expressed in lbs. of coal or lbs. of steam per ton rolled.

The author, however, gave several reasons whereby in his opinion the results of such tests have little value.

The energy consumption of an electrically driven reversing rolling-mill as expressed in kilowatt hours (Board of Trade units) per ton rolled can be determined in the simplest possible manner by inserting an ordinary integrating wattmeter in the supply system, which is an instrument that can always be left in circuit and requires no attention. If a reading of this instrument before the commencement of a shift and a second reading at the end of the shift are taken, the difference gives the total kilowatt hours used during the shift, and dividing this by the tonnage rolled the total kilowatt hours per ton is obtained. Such readings can quite easily be taken for every shift, and a continuous check on the energy consumption can be kept. Results expressed in kilowatt hours per ton are generally found most useful, as the cost of the kilowatt hour varies according to local conditions, and, knowing this cost, the total cost of power can be arrived at directly. The efficiency of the electrical plant can also be checked in the simplest possible manner by placing a second integrating wattmeter in the armature circuit of the mill motor. The records of this wattmeter will be less than those of the one placed in the supply circuit, the difference being the losses in the electrical plant. This does not take account of the efficiency of the mill-motor armature, but as this is of the order of 97 to 98 per cent. it can well be neglected. The following figures show some characteristic values for the kilowatt hours per ton rolled obtained from tests on reversing mills:—

	Kilowatt Hours per Ton.
$4\frac{1}{2}''\times4\frac{1}{2}''$ billets from 2·5-ton ingots. Output, 53 tons per hour	22·5
$6''\times6''$ blooms from 2·5-ton ingots. Output, 63 tons per hour	17·5
$8''\times8''$ blooms from 2·5-ton ingots. Output, 80 tons per hour	13·0
$12''\times9\frac{1}{2}''$ blooms from 7-ton ingots, measuring $34\frac{1}{2}''\times25''$. Output, 65 tons per hour	11·2
$32''\times9''$ slabs from 6-ton ingots measuring $36''\times19\frac{1}{2}''$. Output, 40 tons per hour	4·3
$32''\times5''$ slabs from 6-ton ingots measuring $36''\times19\frac{1}{2}''$. Output, 40 tons per hour	5·8
Flange rails, 100 lb. per yard, from 2-ton ingots. Output, 30 tons per hour	48·0
Beams, 120 lb. per yard, from 1·5-ton ingots	36·0
Channels, 92 lb. per yard, from 1·5-ton ingots	37·0

In opening the discussion, Mr. A. Lamberton, who apparently somewhat misunderstood the title of the Paper, complained

Digitized by Google

that no figures were given to substantiate the author's claim that electrically-driven reversing rolling mills were more economical than steam-driven mills. He would have preferred to see figures of actual costs rather than kw.-hours consumed, as a good deal more than the cost of power had to be considered. He thought that the cost of repairs of electrical mills was higher than with steam, basing his opinion upon insurance reports. With regard to depreciation, he thought that depreciation of electrical plant should be put at 15 per cent., as against 10 per cent. for steam plant. The comparative figures which he would give were 6d. per ton for an output of 300 tons of steel rails in 10 hours for steam driving, and 8·8d. for electrical driving in conjunction with blast furnace gas engines. He suggested that the expense of the Ilgner set might be avoided by a mechanical reversing gear, and showed a drawing of a suggested arrangement with a flywheel on the shaft of a constantly running motor and a clutch reversing gear, using coil clutches for starting the rolls, and an automatic device putting positive clutches into engagement when speed has been attained but before the load has come on. He only suggested this system for mills up to about 30 in. diameter.

The Chairman (Lord Airedale) remarked that the figures which had been given referred to continuous rolling, but probably in cases of intermittent work electrical driving would result in better economy, especially when current was taken from a large power-station.

Mr. Alexander Siemens thought that the cost of power could be much reduced in the figures given, and stated that at his firm's Woolwich works they generated about 1600 kw. at about ¼d. per unit, including depreciation, &c. He emphasised the desirability of employing electrical machinery of ample size for its work. The secret of low upkeep charges was to work the plant within its power. A figure of 15 per cent. for depreciation was not justified where the plant was properly chosen. The great superiority of the Ilgner plant over the mechanical clutchgear described by Mr. Lambert was that the shocks were taken magnetically and not mechanically.

Mr. Ablett, in reply, pointed out that the object of the Paper was not to prove the superior economy of electrical rolling mills, but to encourage steel-makers to investigate the subject. He mentioned an electrically-driven mill which the Rheinische Stahlwerk, of Duisberg, had put down to replace a steam mill. This mill had been running continuously since September 4th last year, two days after it was erected, and had resulted in a saving of 1s. per ton on an output of 5,000 tons per week, and reduced the oil consumption to ⅓ of its former value. Three other large steel works in the same neighbourhood had placed orders for electrical equipments.

A number of special visits were paid in connection with the meeting, those of electrical interest including the works of Messrs. Siemens Brothers & Co., Ltd., at Woolwich, the generating station of the London County Council Tramways at Greenwich, and the National Physical Laboratory. An excursion to Portsmouth Dockyard was made last Friday.

Smoke Nuisance Prosecution.—At the Tower Bridge Police Court last week the City of London Electric Lighting Co. appeared in answer to nine summonses by the Southwark Borough Council for allowing the emission of smoke from their chimney at Bankside. When the summonses were called, a dispute arose as to their adequate service, and the magistrate, not being satisfied that the summonses had been properly served, dismissed them. The defendants then made an application for costs against the Council on the ground that nine summonses had been taken out when one would have been sufficient. The magistrate allowed five guineas costs against the Council.

Electric Lighting and Power at Homerton Infirmary, City of London Union.—On Saturday, Sept. 25th, the new workhouse and infirmary at Homerton, which has been built for the Guardians of the City of London Union, was formally opened by the chairman of the Board, the Rev. Thomas Grear. The new buildings have been designed by Mr. Albert E. Pridmore, architect, and built by Mr. Albert Monk, of Lower Edmonton. The engineering work comprises the heating, hot-water service, electric lighting, laundry, and kitchen, and has all been carried out under the supervision of Mr. E. R. Dolby, M.Inst.C.E. (Dolby & Williamson), Westminster, as consulting engineer. Although there is extensive boiler plant on the premises for heating and laundry purposes, &c., current for the electric lighting of all the new blocks, and parts of the old blocks, is obtained from the mains of the Hackney Borough Council. The lamps are chiefly of the Osram type. The chief rooms are wired upon more than one circuit, so as to prevent total extinction of the light in case of the melting of a fuse. There is also a complete service of telephones and electric bells, and two electric passenger lifts. Electrically driven pumps are used in connection with the heating arrangements, but the laundry machinery is steam-driven. The electric light and power installations were carried out by Messrs. Lund Brothers, of London, and the electric lifts were put in by Messrs. J. G. Childs & Co., of Willesden.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

METAL FILAMENT LAMPS.—A pamphlet from the Electrical Co. (Lamp Department, 121-125 Charing Cross Road) gives particulars of miniature "Aegma" metal filament lamps for use with batteries for voltages from 2 to 14 volts for ¼, ½, and 1 ampere. The company are also sending out an ingenious advertising card, with the inscription, "Our aim is brilliancy and economy," and a device whereby an Aegma lamp can be made to appear in the bull's-eye of a target.

STEEL RODS AND WIRE.—We have received from Messrs. W. N. Brunton & Son (Wire Mills, Musselburgh, Scotland), a well-arranged and concise pocket catalogue of silver-steel drill rods, spring and other steel wires, such as are used for small tools and all descriptions of shafts, straining wires, &c., where a high tensile strain is required, and both tension and compression springs.

MECHANICAL STOKERS.—Illustrations are given in a leaflet now being issued by Messrs. James Hodgkinson, Ltd. (Ford Lane Works, Pendleton, Manchester), of this firm's patent automatic smokeless coking stokers, of which a large number are in use at the Salford Electricity Works and elsewhere.

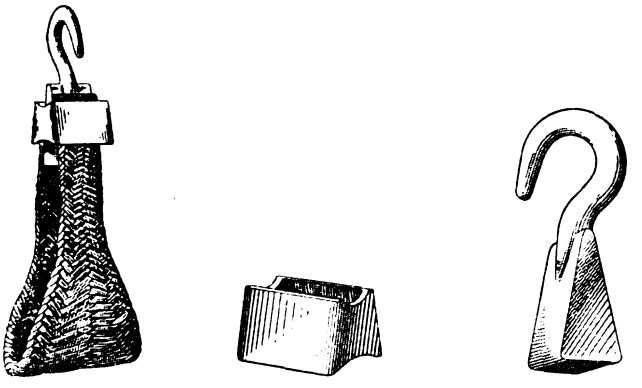
INDUCTION MOTORS.—Messrs. Bruce, Peebles & Co., Ltd. (Edinburgh), give a full description of their latest designs of polyphase induction motors in an attractive new catalogue, and draw attention to the fact that all the standard patterns conform fully with the present Home Office and Insurance Rules, including a special type for use in textile mills. These machines have the apertures fitted with perforated sheet steel, the superficial area of each perforation not exceeding a quarter of an inch square, the holes being at least a quarter of an inch apart. When they are of the slip-ring type, the slip-rings and collector gear are totally enclosed in an iron box, which has inspection holes fitted with plate-glass. Attention should also be called to the automatically short-circuited rotor motors, which are really short-circuited rotor motors having a special rotor winding and an automatic centrifugal attachment, coming into use when the motors have attained a certain predetermined speed. Their advantages, as compared with squirrel-cage motors, are heavier starting torque, with smaller starting current; no auto-transformer starter is required, and the operation of starting is exactly the same as for squirrel-cage motors with a star-mesh starting switch, while the efficiencies and power factors are the same as for motors of the slip-ring type. Complete sets of weights and dimensions are given for all sizes listed, as well as complete lists of outputs, efficiencies, power factors, &c., for 50- and 25-cycle circuits at all the usual speeds.

RADIATORS.—The latest list of radiators from the Dowsing Radiant Heat Co., Ltd. (24 Budge Row, Cannon Street, E.C.), contains illustrations of some new types for this season of special design, such as "Adams," "Flemish," "Georgian," "Sheraton," "Tudor," and others. Convector radiators are also included, as well as a form of combined luminous and non-luminous type, which is made under the Dowsing patents. The latter gives facilities for heating, either by means of hot air, or direct radiation, or both, and a room can be heated in considerably less time by using both systems.

TANTALUM LAMP.—A new folder dealing with tantalum lamps is being issued by Messrs. Siemens Bros. Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department), Tyssen Street, Dalston, London. Any electrical dealer can have a quantity of these, with his name and address printed free of charge, on application.

GAS AND OIL ENGINES.—A booklet from the Empire Engineering Co. (Caxton House, Westminster, S.W.), describes a compact single-cylinder, two-cycle engine, which can be arranged for petrol, paraffin, or gas. These engines are made up to 3 b.h.p., and the whole outfit, which is particularly suitable for country house lighting, is conveniently arranged on one base.

ROLLER BEARINGS.—Messrs. Kynoch, Ltd. (Lion Works, Witton, Birmingham), call attention in a new leaflet to the advantages of their patent roller bearings, for which the co-efficients of friction in repose and motion are claimed to be 0·0115 and 0·0082 respectively, or about one-tenth of the values for an ordinary plain bearing in each case.



Aluminium Combine.—It is stated that an effort is being made to re-establish the Aluminium Producers Syndicate, which was dissolved last autumn.

Brazilian Railway Electrification.—An American Consular report states that a decree has been signed giving the American-Canadian syndicate, which owns or controls the public utilities of Rio de Janeiro, permission to electrify the railway from the city to the top of Mount Corcovado, the unique peak which rises from the edge of the city of Rio de Janeiro to a sharp point 2,300 ft. above the ocean at its base. This will enable the company to afford a rapid and cheaper service up this mountain, near the top of which a new and modern hotel is to be constructed.

NEW CABLE SUSPENDER

MESSRS. W. T. GLOVER & CO., LTD. (Trafford Park, Manchester), have introduced a new patent cable suspender for heavy insulated cables. The sling, the shape of which is seen in the illustration, is made up of sheet lead, which is substantially braided with compounded yarn. The hook and collar are made of galvanised malleable steel, and the lower

Complete Suspender. Galvanised Malleable Steel Hook and Collar on a Larger Scale.

Braided Lead Sling.

part of the end is wedge-shaped, and so proportioned that when the cable is in position the ends of the sling enter the collar without appreciable bending. In the illustration above, the construction of the suspender and method of using it are clearly seen. The replacement of the ordinary eyelet method of suspension by the wedge seems to be a move in the right direction.

PRODUCER-GAS INSTALLATION IN HONG-KONG

IN view of the fact that comparatively few tests of large gas-engines using producer gas have been published, the following figures, which have been sent us by Messrs. Richardsons, Westgarth & Co., will be of interest. Messrs. Butterfield & Swire, of Hong-Kong, have recently equipped a large ship-building yard and engineering works at that port, and the power is obtained from four gas-engines using producer gas. Two engines drive 750-kilowatt direct-current generators, and the other two, 375-kilowatt generators. The larger engines are of the twin-tandem type, and the smaller of the single-tandem type. All the engines are therefore fitted with the same sized cylinders, thus reducing the amount of necessary spare gear, &c. The gas-producers are designed to gasify South Chinese bituminous coal and supply gas to the various furnaces as well as to the engines. The gas supplied to the engines passes through a rotary meter, and this enabled consumption tests to be made. These tests were carried out in November and December, 1908, and were entirely satisfactory. One large and one small engine were tested, and as the results were under the guarantees, the other two engines were not tested in detail.

The gas had an average heat content of 140 B.Th.U. per cubic foot, and the actual consumptions of the two engines are given in the following table:—

Load.	Gas per B.H.P. per Hour.	B.Th.U.'s per B.H.P. per Hour.
Larger Engine—		
1,079 b.h.p.	66·7 cubic feet.	9,330
815 ,,	72·2 ,,	10,100
559 ,,	80·3 ,,	11,240
Smaller Engine—		
544 ,,	64·3 ,,	9,000
430 ,,	72·1 ,,	10,100
289 ,,	79·5 ,,	11,140

The output of the engines was measured electrically, and the b.h.p. obtained from the guaranteed efficiencies of the generators.

The engines are of the Cockerill type, made by Messrs. Richardsons, Westgarth & Co., Ltd. The generators were made by Messrs. Dick, Kerr & Co., Ltd., and the gas producers by Messrs. The Power-Gas Corporation, Ltd. The whole plant has now been working nearly twelve months, and we are informed that it has given satisfaction.

AN "INTERMEDIATE" SWITCH

THE accompanying illustrations represent an improved form of "pivot intermediate" switch which has been introduced by Messrs. A. P. Lundberg & Sons Like the earlier forms of this class of switch, it is intended mainly for use in conjunction with two-way switches to enable a group of lights to be controlled from any number of points at will, an arrangement of great utility in passages, halls, &c. The principal improvements on the older pattern include the adoption of double-clip contacts, and the use of mica insulation in the rocking contact-

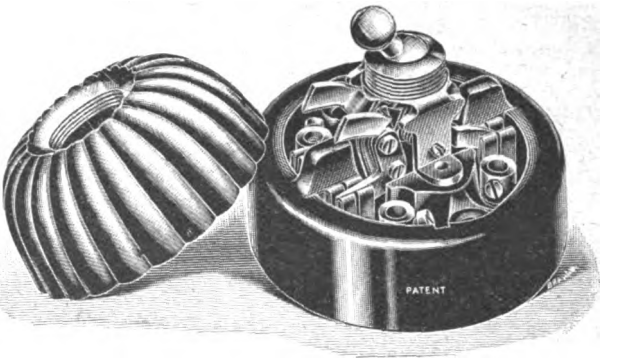

Fig. 1.—"Pivot Intermediate" Switch and Cover.

arm. The screws which hold the various members of the rocking contact-arm together are all provided with porcelain bushes, and the construction is now proof against breakdown which might otherwise be caused by overheating or moisture.

The provision of double-clip contacts is almost a necessity in this type of switch, as the current is passing through the switch in only one of four possible ways at a time.

The path for the current is therefore varied, as all switches in circuit are in series with each other, the need of efficient contact everywhere is an essential requirement.

The modified switch movement adopted has allowed an improved method of construction for the rocking contact-arm, and this forms the subject-matter of two new patents recently granted to the firm.

This switch is easily converted by the omission of one of the U-shaped contact-arms, into a series parallel switch without

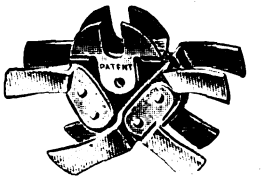

Fig. 2.—Moving Contact Piece.

"off" position, and by the removal of *two* of the U-shaped contact-arms, into a double-pole switch. The latter type of switch, although not one in favour in this country, is a type that has considerable adoption on the Continent. The "Intermediate" switch, without any alteration to the rocking contact-arm, also acts as an efficient reversing switch, without an "off" position. In these three adaptations the switch would be preferably fitted with porcelain covers, or, if of metal, would have fibre linings, to avoid risk of short-circuiting. The switch is made for both surface (2½-in. base) and flush work (1⅞-in. base).

Construction of Magneto Armatures.—We announced in our Patent Record a few weeks ago that the grant of a patent, No. 7,125/08, to the firm of Robert Bosch, for non-magnetic steel end-pieces for magneto armatures, was refused in August last in consequence of opposition (*see* Electrical Engineering, August 5th, p. 714). The invention claimed was the construction of each end-piece and spindle of a shuttle armature in one piece of non-magnetisable steel, such as nickel steel, which arrangement gave a rigid connection without closing the magnetic circuit. It now appears that the grant was opposed by Mr. F. H. Hall, a director of the Electric Ignition Co., Ltd., on the ground of anticipation in a patent (No. 3,997/07) granted to that company and himself. This patent was for end-pieces and spindle-halves formed in one piece of non-magnetic material, but only brass and bronze were mentioned as suitable materials. The Comptroller held that the latter patent was not restricted to brass or bronze, and refused to grant a patent on Bosch's application. On appeal, the Law officer, Sir Samuel T. Evans, held that although a patent could be granted for selecting the best material, the suitability of which was not previously known, the test was whether the selection involved invention. In this case, non-magnetisable steel, such as nickel steel, was well known to be suitable for the purpose, and therefore he dismissed the appeal with costs.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 30th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

18,996/08. **Automatic Railway Block Signalling.** G. H. Brown. Improvements in the automatic signalling system covered by the patents of Brown and Mackenzie are described in this specification. An incoming train is caused to notify its approach to the cabin controlling the section it is on, to block that section when leaving it, and to notify its approach to the cabin controlling the section ahead. Further, it notifies its departure to the cabin controlling the section in the rear of that just left, and clears it. Intercommunication is arranged for between signalmen and drivers, and when approaching a terminus the number of the platform assigned to the train can be indicated in the driver's cab. Trolley mechanism for attaching to engines, and means for automatically stopping the train on passing a danger signal, are also described. Seven claims, fourteen figures.

19,353/08. **Heating Apparatus.** C. O. Bastian. A spiral wire or zig-zag ribbon of any suitable resistance material is brought to a red heat in an enclosure of quartz or other material transparent to heat rays and capable of resisting a high temperature. In a commercial form of this heating unit, described in Electrical Engineering, July 8th, p. 631, a 0·4 mm. soft nickel wire wound into a spiral is inserted into a quartz tube of 3 mm. bore. The wire is run at a temperature of about 1,000° C., and is brought to this temperature within ten seconds. Eight claims, eleven figures.

20,647/08. **Tramway Overhead Construction.** J. O. Ormston and W. E. Charlton. To obviate the necessity for removing the trolley from the wire when reversing the direction of travel, an off-set portion or section parallel to the track for some distance is provided. The trolley-pole is thus carried out at right angles to the car, and on the car starting in the reverse direction takes up the normal position without being removed from the wire. To prevent trouble with poles of different lengths or at different heights, the off-set portion can be made automatically adjustable. Four claims, four figures.

21,912/08. **Wiring Fitting.** Siemens Bros. & Co., Ltd., and J. S. Huddleston. This is a clamping device for the switch, fuse or joint boxes, or ceiling roses of a concentric wiring system with earthed outer. It comprises a metal clamping ring with two or more V-grooves or seatings, which is screwed to a metal base plate. The ring surrounds an interior porcelain piece containing the terminals or other fittings and fixed to the base plate. The outer metal sheathings of the conductors are firmly gripped between the clamping ring and the base. Two claims, six figures.

25,954/08. **Magnetic Blow-outs for Circuit-breakers.** T. von Zweigbergk. In circuit-breakers for D.-C. circuits of 3,000 to 4,000 volts, the current density in the blow-out coils has, it is stated, to be of the nature of 20,000 to 28,000 amps. per sq. in. in order to bring the size and cost of the coils within practical limits. Auxiliary contacts are sometimes used to charge the blow-out coil just before the switch is opened, but these are not always satisfactory. According to the present invention, the current in the blow-out coil depends on the position of the arc to be blown out. Besides the two main contacts, a third contact is provided, and the blow-out coil is connected between this and, say, the positive main. Normally, no current passes through the coil, but directly an arc is formed, it is transferred from the main positive contact to the auxiliary contact, so that the whole current passes through the blow-out coil. A special arrangement is described by which the blow-out coil is normally in series with a high resistance, the two being shunted across a low series resistance in the main circuit. On the arc jumping to the auxiliary contact, the two resistances are in series and are shunted across the coil, which then carries the main current. Four claims, two figures.

28,485/08. **Cables for Overhead Suspension.** C. J. Beaver and E. A. Claremont. In weatherproof cables a fibrous covering is usually applied direct to the stranded conductor and treated with a preservative compound. Such coverings are sometimes attacked by chemical fumes, and, further, do not entirely exclude moisture from the interstices of the stranded conductor. According to this invention, the spaces between the strands are filled with a waterproof compound, and the whole covered with asbestos braiding saturated with a bituminous compound. One claim, one figure.

Opposition to Grant of Patent

22,964/08. **Lamp Shade Gallery.** S. Falk (Falk, Stadelmann & Co.). Opposition has been entered to the grant of this patent, an abstract of which appeared in Electrical Engineering, August 26th, p. 768. Secured to the gallery are cylinders containing spiral springs which press pins upon the shade rim. The pins are held outwards by pulling them out and giving them a turn.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.
Names in italics indicate communicators of inventions from abroad.
Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Jaburg, 19,395/08.

Distributing Systems, Cables and Wires, Insulating Materials, Etc.: Bruce [Connector for wires and cables] 19,873/08; Geppert [Protection of pipes from electrolysis] 4,353/09.

Dynamos, Motors, and Transformers: Stansfield and Hatt [Voltage control of variable-speed generators] 12,704/08; Macdonald [Motors for submerged pumps] 19,384/08; British Thomson-Houston Co. (*Allgemeine Elektricitäts Ges.*) [Driving of rolling mills] 19,485/08; Akt.-Ges. Brown, Boveri et Cie. [Regulation of machines] 19,921/08.

Electric Ignition: Hall [Ignition apparatus for engines] 11,223/09; Lake (*Fabrik Elektrischer Zünder Ges.*) [Magneto for firing igniters] 14,126/09.

Electrometallurgy and Electrochemistry: Hurford [Extraction of nitrogen from air] 19,402/08; Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges*) [Electrolysis of aqueous saline solutions] 605/09; Bleeck [Primary cell] 15,194/09.

Incandescent Lamps: British Thomson-Houston Co. (*Allgemeine Elektricitäts Ges.*) [Lamps] 26,287/08.

Instruments and Meters: Lockhart and Christie [Money registering mechanism for prepayment meters] 20,128/08.

Switchgear, Fuses, and Fittings: Mygatt [Lamp shades and reflectors] 10,708/08; Ashley [Electric light fittings] 26,145/08; Wright [Means for converting ordinary lamp holder to switch holder] 3,637/09; Kallmann [Starters for A.-C. induction motors] 6,957/09.

Telephony and Telegraphy: Muirhead [Telegraphy] 19,450/08; Eisenstein [Wireless telegraphy] 17,217/09.

Miscellaneous: Vetter and Mürer [Device for producing intermittent motion] 19,151/08; Newitt, Webber, and Standard Time Co. [Electric clocks] 19,458/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: Akt.-Ges. Brown, Boveri, et Cie. [Control of dynamos for accumulator lighting installations] 16,631/09.

Telephony: McBerty [Automatic selective switching apparatus for exchanges] 20,839/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: British Thomson-Houston Co. (*C. E. Harthan, U.S.A.*) [Lamp with two pairs of carbons in series] 13,732/02; F. Harrison [Mercury vapour lamp] 12,337/05.

Distribution Systems, &c.: J. Y. Johnson (*Hartmann & Braun*) [Concentric conductors and wiring fittings] 12,668/99; Veritys, Ltd., and W. G. Pipkin [Wire connectors] 12,205/05; T. B. Reader [Junction boxes] 12,473/05.

Dynamos, &c.: Otis Elevator Co. (*Otis Bros. & Co., U.S.A.*) [Control of A.-C. lift motors] 12,297/99.

Electrometallurgy and Electrochemistry: W. P. Thompson (*Litzelmann & Tailfer, Paris*) [Apparatus for decomposing amalgams] 10,925/00; B. J. and E. C. Blaineuser, N. Kribs, and W. J. Bauerle [Primary fluid cell] 12,315/05.

Incandescent Lamps: F. R. Pope [Candle lamps] 12,536/05.

Instruments and Meters: Hartmann & Braun Akt.-Ges. [Coils for moving-coil instruments] 11,442/05; M. B. Field [Power-factor or phase indicator] 12,431/05.

Switchgear, &c.: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Motor starter] 13,569/04.

Telephony and Telegraphy: C. Adams-Randall [Telephone transmitters] 13,250/96; R. J. Sheehy and A. G. Curphey [Selecting devices] 13,674/03; R. Knoll [Telephone mouthpiece] 12,406/05.

Traction: British Thomson-Houston Co. (*S. H. Libby, U.S.A.*) [Third rail construction] 14,476/97; L. Krieger [Mounting automobile motors] 12,697/99; J. E. Spagnoletti [Signalling] 12,089/01; R. C. Taylor [Brakes] 13,589/04; G. L. Fowler [Brakes] 13,590/04; R. C. Lowry [Increasing adhesion of wheels magnetically] 12,296-7/05; J. P. Lowe and D. F. Boissevain [Operating points from car] 12,319/05; P. J. Portman, W. M. Diepenbrock, and G. H. Meinen [Signalling] 12,352/05; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Multiple unit control] 12,594/05.

Miscellaneous: H. J. Haddan (*Bergmann Elektricitäts-Werke Akt.-Ges.*) [Electromagnetic separators] 13,570/03; R. J. Sheehy and A. G. Curphey [Selective switching devices] 13,674/03; F. O. Schnelle [Electrostatic separators] 13,489/04; Clarke, Chapman & Co., and H. Walker [Electric steering gear for ships] 12,446/05.

It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

A patent taken out by Mr. Gisbert Kapp fourteen years ago, and covering the use of a negative booster on tramway systems, expires next Saturday. The patent has, however, been recognised by only a limited number of tramway undertakings. (Page 891.)

An electrolytic meter with many novel features will shortly be on the market. It is the invention of Mr. W. B. Thorpe, and is a watt-hour meter, and not merely an ampere-hour meter. An electrolytic cell is connected across the mains, and the current passing through it is determined by the mains pressure as well as by the load current passing through the shunt. Recombination of the evolved gases is effected after every one or two units of energy passed by the meter, and the firing current works an electromagnetic registering dial. The drop across the shunt is less than one volt at full load, and the temperature error has been eliminated. Mr. Thorpe has also developed an electrolytic time-limit relay for circuit breakers. Electrolysis is started on the occurrence of an overload, and continues until a certain quantity of gas is evolved. This is then automatically recombined, and the tripping coil circuit closed. If the overload has ceased before the electrolysis is completed, the tripping-coil circuit is not closed, but recombination is effected, so that the full time lag is obtained with the next overload. An automatic motor-starter controlled by a similar device, will also be placed on the market. (Page 891.)

Mr. C. J. Robertson, Engineer and Manager of the Robertson Lamp Works, died of typhoid fever on Thursday last. (Page 894.)

The following books are reviewed in this issue: "Practical Calculation of Transmission Lines," by L. W. Rosenthal; "Technical Electricity," by H. T. Davidge and R. W. Hutchinson; "Electricity for Everybody," by R. Borlase Matthews; and "Examination Questions on Electrical Engineering set by the City and Guilds Institute, 1900-1908." (Page 894.)

A new form of turbo-pump, which has been brought out by Messrs. Willans & Robinson, is described on page 985.

In an original communication accepted by the Institution of Electrical Engineers, Mr. L. H. Walter describes some experiments showing that tungsten has the property of acting as a "valve" electrode. (Page 897.)

Digitized by Google

Statistics which have been published relating to electricity supply in Germany show that there were 1,978 generating stations in operation in April, 1909. Over half of this number had no gas supply to compete against. Some 37,700 kw. was connected in heating and cooking apparatus at that date. The returns also emphasise the extensive adoption of overhead distribution networks, and the large number of systems working with continuous current. (Page 898.)

We describe a convenient method of filing and indexing catalogues, which is used at the Electrical Standards Laboratory of the Board of Trade. (Page 898.)

The Home Office are prosecuting two mine managers in Scotland in respect of recent explosions, the case being that they had knowingly allowed their electrical installations to get into a bad state of repair. One of these actions was heard on Tuesday at Hamilton, Lanarkshire, when Mr. Andrew Salmond, Ferniegore No. 1 Pit, was prosecuted by the Crown. Mr. R. Nelson, H.M. Electrical Inspector of Mines, and others gave evidence, but finally Mr. Salmond was acquitted. It is suggested that manufacturers of electrical plant should be represented upon the Home Office Committee about to be appointed. The need for prohibiting the use of electrical machinery in dry and dusty mines, owing to the dangers of explosion, was referred to at the Miners' Federation Conference last week. The appointment of a Minister of Mines was also advocated. (Page 899.)

An application by the "Z" Electric Lamp Syndicate for further particulars in the pleadings of Messrs. Marples, Leach & Co., in the patent action instituted by the former, was refused in the Appeal Court on Tuesday. (Page 900.)

The balance sheet of the Manchester Electrical Exhibition of 1908 shows a profit of £6,317. After returning to exhibitors an amount equal to 20 per cent. of the rental of their spaces at the Exhibition, and to donors an amount equal to 10 per cent. of their donations, &c., the sum of £740 remained, and has been distributed among a number of benevolent institutions. (Page 901.)

Among the novelties at the Electrical Exhibition at Hampstead last week were some new candle fittings, an improved pattern of electric flat-iron, a vertical "Bastian" quartz heater, and an oven on the same principle. Electric light fittings and radiators and other heating devices were most prominent. (Page 901.)

Among the specifications published by the Patent Office on Thursday last was one by H. J. Jaburg for a converging carbon flame arc lamp with neither feeding nor regulating mechanism. The British Thomson-Houston Co. protect a method of limiting the current in systems for dealing with fluctuating loads by regulating the field of the generator, consisting in weakening the generator field or strengthening the motor field when the current exceeds a predetermined amount. The same company also covers a system of decorative lighting, in which special double-capped lamps are strung in series. Manganese peroxide anodes for electrolytic baths containing free acid are described by Siemens Bros. & Co. E. B. Wright has a specification for an adapter for converting ordinary lamp-holders to switch-holders, and H. Geppert describes a method of preventing the electrolysis of pipes and cable sheaths by stray traction currents. The grant of a patent to J. Howden & Co. relating to exhaust steam plant is opposed. A patent for a single-phase commutator motor has been granted to the Felten & Guilleaume Lahmeyerwerke A.-G., in spite of opposition. The master patent by Prof. G. Kapp, covering the insertion of boosters in the negative feeders of traction systems, expires on Saturday. Other expiring patents relate to railway signalling and fire-bars for boiler furnaces. (Page 902.)

Several cases of electrical interest are down for hearing during the present law term. The British Thomson-Houston Co. are sueing the Midland Railway Co. for alleged infringement of their multiple-unit control patents in the equipments on the Heysham-Morecambe line. Another case refers to an alleged infringement of the Ilgner patents for the electric driving of reversing rolling mills by the Electric Construction Co., and a dispute in connection with the case for the revocation of these patents is also to be settled. An action brought by Messrs. J. H. Holmes & Co. against the Associated Newspapers, Ltd., concerning the Clatworthy and Kohler patents for the electric driving and control of rotary presses will also be heard. It is also rumoured that an important action is to take place regarding metal filament patents, but this is not yet set down in the lists. (Page 903.)

The Belfast Tramways Committee have been asked by some ratepayers not to remove the central tramway standards.—The Fleetwood Council have completed the purchase of the local electric supply company.—The City Corporation have leased the tramways over Blackfriars Bridge to the L.C.C. for 21 years at a rental of £500 per annum.—Mr. C. P. Sparks has been appointed at a fee of 250 guineas to report upon the Newport (Mon.) electricity undertaking.—Mr. W. H. Hall has resigned his position as electrical engineer to the Morecambe Corporation.—The first electrically operated jute mill has been opened in India. (Page 903.)

Wallasey Corporation require cables and overhead line material, and the Great Western Railway Co. and Mountain Ash Council electrical stores. Large tramway extensions are contemplated by the Johannesburg Corporation. (Page 905.)

The accounts of Messrs. Drake & Gorham show a profit for the year to June 30th of £3,609. A dividend of 2½ per cent. is declared. (Page 906.)

A circular has been issued to the shareholders of Marconi's Wireless Telegraph Co., expressing the directors' satisfaction with the sale to the Post Office of the company's coast stations. It is also stated that Transatlantic communication *via* the Glace Bay station, which was recently destroyed by fire, will be reopened early in the New Year. The Indian Government is erecting a wireless station at Bombay. (Page 906.)

ARRANGEMENTS FOR THE WEEK

TUESDAY, OCTOBER 19th.

South Wales Institute of Engineers.

2.30 p.m. Quarterly meeting at Cardiff. Among the Papers down for reading is the following:—"The Electrification of the Ferndale Collieries," by W. H. Patchell.

WEDNESDAY, OCTOBER 20th.

Dynamicables.

7 for 7.30 p.m. Dinner at the Trocadero Restaurant.

FRIDAY, OCTOBER 22nd.

Physical Society.

5 p.m. Meeting at the Imperial College of Science, South Kensington. Among the Papers down for reading is the following:—"On Cadmium Amalgams and the Normal Weston Cell," by F. E. Smith.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Opening meeting in the Banqueting Hall of the Midland Hotel, when the Chairman, Mr. S. J. Watson, will deliver his Address.

Electro-Harmonic Society.

8 p.m. Smoking Concert at the Holborn Restaurant (King's Hall).

SATURDAY, OCTOBER 23rd.

Junior Institution of Engineers.

7 p.m. Conversazione at Caxton Hall, Westminster, London.

THE NEGATIVE BOOSTER PATENT

ON reference to our "Patent Record," it will be seen that among the electrical patents expiring this week after a full life of 14 years is Dr. Kapp's patent for the "negative booster," the well-known and widely-used device for complying with the regulations limiting the potential difference on tramway rail returns.

Dating from 1895, this patent would seem to have been of most timely birth, as the great expansion of electrical tramways was then at its commencement, and the rail drop limitation had to be complied with. But it is doubtful whether the patent has produced such an income to its inventor or assignees as its apparent timeliness and value would suggest. Dr. Kapp was in Germany at the date of the patent, and for several years afterwards, and the patent was offered in several quarters, about 1898, without, so far as is known, securing either buyers or licensees; and it is certain that the negative booster was widely used by many undertakings which paid no royalties to the inventor, and that no action was taken to obtain royalties for a long time. The earliest recorded use is believed to be on the Dublin Tramways, about 1897, by Mr. Parshall. It is fair to say that various engineers advising tramway companies and contractors, who were then aware of Dr. Kapp's patent were of opinion that it could not be successfully defended, but that opinion has never been put to the test. During the last few years of its life the patent has been owned by the British Westinghouse Company, which has made some efforts to enforce it, and has collected royalties from a number of users, though not by any means all.

As the patent then had only two or three years to run, and the owners only asked comparatively modest terms for the use of it, it was not worth the while of any particular user to fight the patent, or a very interesting case would doubtless have come before the courts.

No one will grudge Dr. Kapp whatever he may have made of his very opportune invention, but it is not quite agreeable for a concern which has used a machine freely for several years to be suddenly called upon to pay up royalties, even modest royalties. In this particular case it was no doubt very difficult to trace infringement, because the invention patented is essentially a particular use of a well-known machine, viz., a series wound dynamo, in combination with a feeder cable, and neither the cable maker nor the dynamo builder could be accused of infringement. That lay with the user who put the things together.

ELECTROLYTIC METERS AND TIME-LIMIT RELAYS

AFTER many years of experimenting, Mr. W. B. Thorpe has succeeded in developing an electrolytic meter which records kilowatt hours instead of being merely an ampere-hour meter. This meter, which will be exhibited for the first time at the East London Electrical Exhibition at Shoreditch next week, will shortly be placed on the market, together with two other electrolytic devices, an automatic motor starter and a time-element relay, by Mr. Haydn Harrison, of 11, Victoria-street, Westminster, S.W., who is sole selling agent for the Thorpe Meter Syndicate, Ltd.

The principles upon which the meter works are quite novel, and the means by which the many difficulties in practical construction have been overcome are most ingenious. Among the features claimed for the meter are the following:—

It registers the slightest current passing.
Although a shunted meter of the water type, it has not more than one volt drop at full load.
It is a wattmeter, and not merely an ampere-hour meter.
It has a dial like an ordinary motor meter, and requires neither refilling nor resetting.
No chemicals likely to give trouble in the future are used.
The cost is approximately half that of a motor wattmeter.
It has no temperature error.
It possesses approximately a straight line characteristic.

A view of a meter from which the case has been removed is given in Fig. 1. The meter is worked on the principle of the continuous electrolysis and recombination of water containing a small percentage of caustic soda in an hermetically sealed tube. Recombination of the evolved gases is effected automatically after a definite amount has been produced, and each recombination, corresponding to one or more units of electrical energy passed by the meter, is registered on a dial by an electromagnetic device. An electrolytic wattmeter of the water type with less than 1-volt drop at full load seems, at first sight, impossible of attainment, and it is necessary that a detailed description should be given before its feasibility and mode of operation can be fully grasped.

Considering the diagram of Fig. 2, E is the "registering" cell which, it will be noticed, is not connected directly across the main shunt R, but is placed across the mains in series with a high resistance G and another high resistance F, these being so proportioned that the pressure across ac is about equal to the back EMF of the cell, while that across ad is the full mains' pressure of 100 or 200 volts. The other end b of the main shunt R is connected to the point c

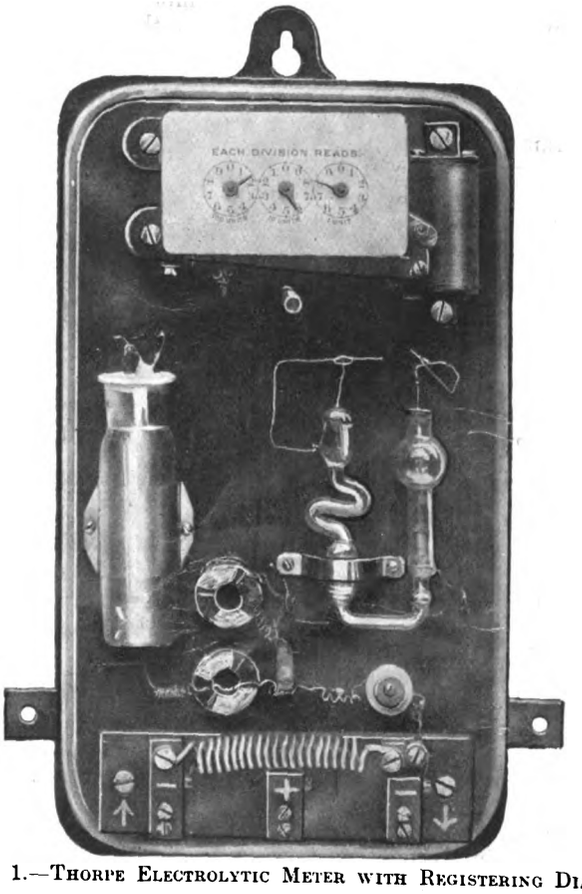

FIG. 1.—THORPE ELECTROLYTIC METER WITH REGISTERING DIAL.

Digitized by Google

through a resistance H, and therefore, neglecting the drop across R, the pressure across H is also about equal to the back EMF of the cell. First, with regard to the effect of variations in pressure, a rise in the main voltage would cause a larger current to flow through H and E than normally, and this would result in a rise of pressure across bc and ac. Although a very slight rise of pressure across the cell E is required in order that it may register an increased energy consumption in proportion to the increase of pressure, the actual rise consequent upon the total rise across ad would be too high. This rise could not be reduced by altering the proportions of F, H, and G, as it is essential that the pressure across bc should be about the back EMF of the cell, so it was necessary to devise a third parallel path to E and H which would take the extra current consequent upon the increase in the mains' pressure without increasing the drop across ac and bc. An electrolytic cell J, called the "absorption cell," is employed for this purpose. It comprises a test tube in which are two plates of nickel 160 mm. square immersed in a 20 per cent. solution of caustic soda. If these nickel plates were infinitely large, the cell would take any current without any rise in the pressure across bc, which would remain at the critical voltage of the cell. Actually, however, they are of such dimensions that the pressure across bc (and therefore across ac) rises in proportion to the increase in the

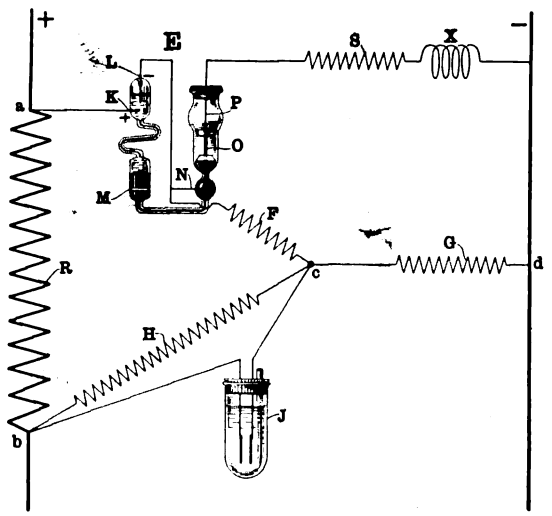

Fig. 2.—Diagram of Connections of Thorpe Electrolytic Wattmeter.

supply pressure to such a degree that the cell registers an increased amount, making the meter in effect a wattmeter. It should be mentioned that practically no gas is generated in the "absorption cell" the little that is generated being occluded in the plates.

When the load circuit is open the various pressures are so balanced that the voltage across the registering cell E is very slightly more than the back EMF of the cell. This balance is obtained in setting the cell in the first instance by adjusting the resistance H, this being the only adjustment necessary to set or correct the meter. A very minute quantity of gas is evolved under these conditions, but this is occluded by the nickel electrodes, and does not influence the reading of the meter. Directly the load circuit is closed, however, current flows through R, and a difference of potential is produced between the points a and b. This difference of potential is immediately effective in driving a current through the cell E, as it raises the pressure across ac. This increase in the pressure being proportional to the drop across R, the water is electrolysed in proportion to the current taken, and, further, any variation of the supply pressure is accompanied by a corresponding variation in the amount electrolysed, as already explained, so that the rate of electrolysis at any instant is proportional to the watts then being consumed by the load. At full load the cell takes a current of about 0·003 amp.

The cell E is hermetically sealed, and therefore the electrolyte never requires replacing. Recombination is effected as follows:—Starting with the left-hand bulb entirely filled with the electrolyte, a quantity of oxygen and hydrogen is evolved by the passage of current until, after one, or, in the large meters, two, units have been passed, the level has fallen to that indicated in Fig. 2. At this point the mercury in the bend of the arm has been displaced so that the wooden float O (which has platinum contacts at each end connected together) comes into contact with P and completes the circuit through the registering cell, the platinum contact N sealed into the mercury bulb, and the series resistance S. Immediately a much more rapid decomposition of the electrolyte commences, and continues for a second or so until the level sinks below the tip of the electrode L. A spark occurs when the circuit is broken here, and the gases are recombined so that the electrolyte again fills the bulb. This cycle of operations is then repeated. In series with the resistance S is an electromagnet X, which operates a registering dial of the ordinary pattern, causing it to record a further one or two units every time the circuit is completed. It should be mentioned that the presence of this inductive winding ensures a strong spark when the circuit is broken at the level of the electrolyte, making recombination certain.

Among the other interesting points are the means of obviating the access of gas or electrolyte to the air bulb, or *vice versa*, and the prevention of any temperature error. It has been found that mercury makes a gas- and water-tight joint with platinum, so by the insertion of a platinum ring at M, the escape of gas or electrolyte is prevented. The ring is fused into the interior wall of the bulb. With regard to the effect of temperature variations, it will be seen that the air and the gas will be affected equally, and the coefficients of expansion being the same, no error will be introduced. Oxidation at the surfaces of the mercury is said to be entirely prevented by placing the mercury in connection with the kathode through the contact N; to increase the resistance of the circuit through the mercury and the electrolyte to K (a path in parallel with the cell proper), a fine capillary tube is inserted below the cell and the mercury column, which offers a high resistance.

The drop across the shunt at full load varies between one quarter of a volt and one volt according to the size of the meter. It is stated that the meter will read correctly with a pressure variation of ± 20 per cent.

In order to compete with the cheaper patterns of meters, a direct-reading meter operating on the same principle as the dial meter but omitting the dial and electromagnetic recording device has been developed. In this meter, illustrated in Fig. 3, electrolysis of the liquid goes on continuously when current is being taken, recombination being effected by pressing a key, which completes the firing circuit, at the end of the quarter or shorter period when the meter is reset. As the gases are evolved, the electrolyte is forced backwards down the long graduated tube on which a reading can be taken to within one quarter of a unit. This pattern is made to record with currents up to 10-amps., and three sizes are made with capacities of 250, 500, and 1,000 units respectively. Should the energy consumed in the period between inspections exceed the capacity of the meter, a device comes into action which cuts out the cell. Resetting, which consists merely in pressing the key, can be done without opening the case.

Digitized by Google

The time-limit relay, a model of which will also be on view at the Shoreditch Exhibition, comprises an electrolytic cell similar to the "registering" cell of the meter with the addition of a second arm to the right-hand side of the tube, as illustrated in Figs. 4

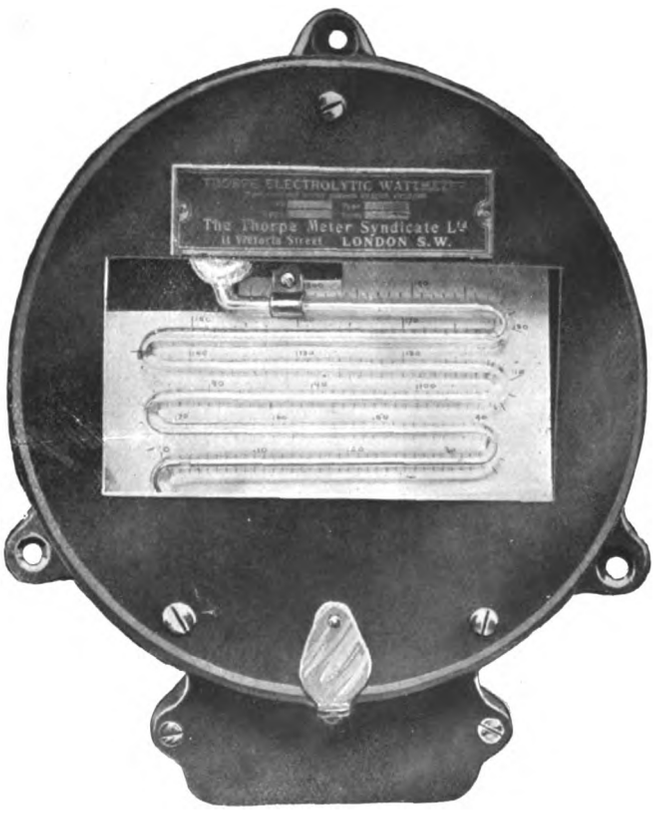

Fig. 3.—Electrolytic Meter for Small Installations.

and 5. Referring to Fig. 4, it will be seen that on the occurrence of an overload, the series coil W closes the cell circuit at Y. Directly electrolysis commences

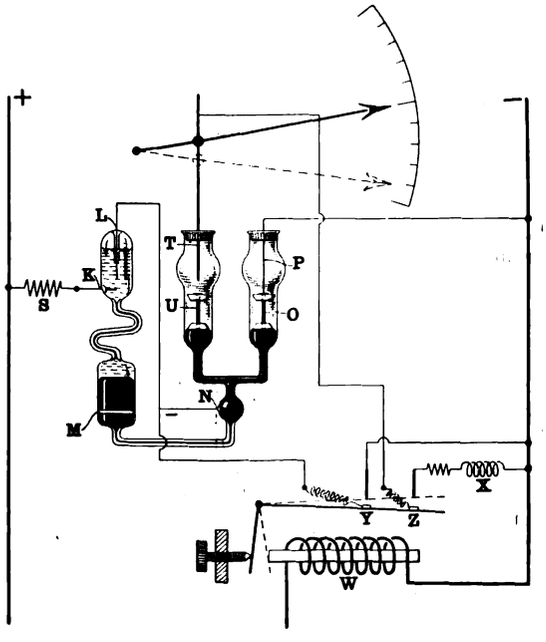

Fig. 4.—Diagram to Illustrate Operation of Electrolytic Time Limit Relay.

the float O is lifted so that a circuit is completed through P and N; the object of this will be seen presently. If the overload continues, electrolysis continues until the float U comes in contact with the adjustable contact T. This completes the circuit of the tripping coil X through Z, and the main switch

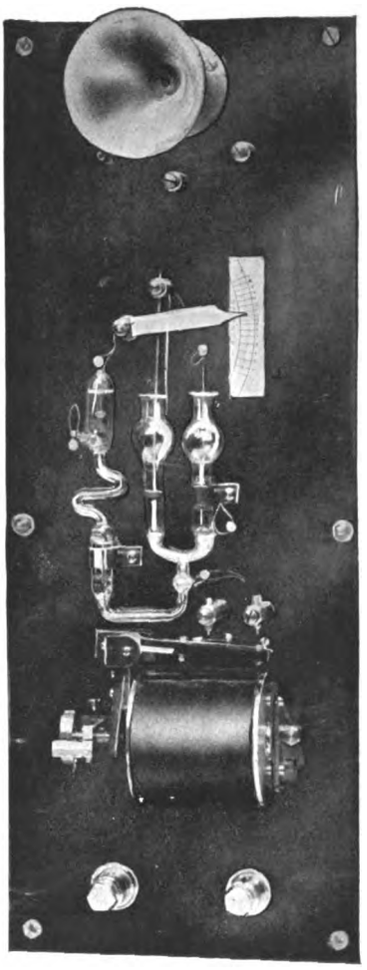

Fig. 5.—Electrolytic Time-limit Relay.

is opened. The time which elapses before this occurs is determined by the position of T, and is denoted on the scale in seconds, so that the relay can readily be set to any desired value of the time. Should the overload cease before the predetermined time has elapsed, however, the cell circuit is opened at Y, but remains closed through the contact at P, so that the electrolysis continues until the float U touches T as before. In both cases the evolved gases are fired almost immediately after this by the breaking of the circuit at the level of the electrolyte, as in the case of the meter, but in the latter case contact between U and T does not complete the tripping coil circuit, as it is broken at Z owing to the overload magnet having weakened. After even a momentary overload, however, the complete cycle of electrolysis and recombination takes place, so that a definite and constant time element is ensured. Although the right-hand bulbs of the cell are open to the atmosphere, the platinum-mercury joint at M prevents the escape of the gases or electrolyte, and the cell therefore never requires refilling. This relay can be applied to any circuit breaker by substituting a shunt tripping coil for the usual series coil.

We have not yet seen the automatic motor-starter, but this has a cell of the type used in the dial meter, the starter arm being moved one step forward after each recombination of the gases. The time between each recombination can be adjusted, and on the final stop the cell is cut out of circuit.

We are indebted to Mr. W. B. Thorpe for his assistance in the preparation of the above article.

OBITUARY

C. J. Robertson.

We learn with regret of the death last Thursday at the age of forty-nine of Mr. C. J. Robertson, whose name has been well known as engineer and manager of the Robertson Electric Lamp Works, Hammersmith, since its inauguration in 1893. Mr. Robertson's connection with carbon filament lamp manufacture commenced as early as 1879, when he was associated with Mr. St. G. Lane Fox. He was subsequently connected in this country with the Gatehouse lamp (Pilsen-Joel Company) and the Bernstein lamp (Bernstein Electric Light Company), the manufacture of which was discontinued on the closing of all factories except those working under the Edison patents. Like several other lamp experts, he was compelled to transfer his field of action to the Continent, where he managed incandescent lamp factories successively in Holland and Vienna. On the expiration of the Edison patents he was invited to return to England to take part in the foundation of Robertson Electric Lamps, Ltd., in conjunction with the leading spirits of the General Electric Co.

At the funeral at St. Peter's Church, Mount Park Road, Ealing, and at the interment at St. George's Cemetery, Hanwell, a large number of workers from the Robertson and Osram factories were present, and representatives of several societies with which Mr. Robertson was connected, including the Hammersmith Lodge of Freemasons.

REVIEWS OF BOOKS

Practical Calculation of Transmission Lines. By L. W. Rosenthal. 91 pp. 6 in. by 9½ in. (New York: McGraw Publishing Co.) $2.

As explained by the author in his preface, this is not intended to be a text-book for students, but a handbook for the practical engineer to aid him in the rapid and accurate calculation of transmission lines. It is divided into two parts, the first of which, dealing with direct-current distribution, occupies only one-quarter of the book, the remaining three-quarters being devoted to alternating-current problems. The mode of treatment is novel, and the author has to a large degree succeeded in his attempt to bring most problems relating to the size of conductors in distributing or transmission systems down to a mere matter of substitution values for certain factors in the formula for the particular case. The various problems relating to current-carrying capacity, pressure drop, charging current, power factor, &c., for overhead, underground, and "interior" circuits are discussed very briefly, and in each case a formula is evolved with which any particular case can be dealt with. There are over one hundred such formulæ in the book, involving the use of some fifteen or more "factors," the values for which, under different conditions, are set out in tables. The author has elaborated a system of ready-made variables for use in his formulæ, such as "heat," "weight," "temperature," "reactance," and "capacity" factors, in place of the more usual international constants (specific heats and weights, and temperature coefficients, &c.), so that it is difficult to appreciate the actual physical meaning of some of the quantities dealt with, and to check their values from first principles. Many of these "factors" are merely given values in tables and are not defined at all. Some extra labour will be required by British engineers using the book, as the wire sections are expressed always in Browne & Sharpe Gauge, and in circular mils. In the alternating-current part a large number of examples are worked out with the aid of the formulæ and tables given, but a previous knowledge of the characteristics of transmission lines and the effects of inductance and capacity is assumed. In neither portion of the book is the determination of the size of conductors for conditions of maximum economy dealt with. The impedance of rails and the effect of frequency and other factors in calculations referring to distribution for single-phase railways, are briefly discussed in the last chapter of the book, and some formulæ and tables for use in such calculations are given.

Technical Electricity. By H. T. Davidge and R. W. Hutchinson. (Second edition.) 528 pp. 7 in. by 4¾ in. 273 illustrations. (London: University Tutorial Press, Ltd.) 4s. 6d.

In conformity with the general aim of the series of text-books published by the University Tutorial Press, the authors of the present volume have endeavoured to produce a work combining scientific principles with engineering practice, in order that the reader may acquire a knowledge of the elements of practical electrical engineering based on sound scientific principles. There is always a danger that such books as this, which touch upon almost all branches of electrical work, will give quite inadequate explanations in many cases of the phenomena and apparatus involved, but the present volume contains quite a large amount of useful practical information. A praiseworthy feature is the evident care that has been taken to prevent the student from getting confused over the physical meanings of, and the relations between, the various units. Besides the more usual elementary matter, the construction of modern laboratory and commercial instruments, lamp testing, systems of charging, and other important subjects are touched upon, and a whole chapter is given to house wiring. Absolute perfection is, of course, not to be expected. A defect in the method employed is that instead of giving the principles and general features of construction of the various pieces of apparatus described, the authors have in many cases singled out a single maker's pattern, and have dealt with it as if it were the only one of its class. For example, the uninformed reader would come to the conclusion that the "Excello" lamp was the only arc lamp operating on the "flame" principle, and that hot-wire measuring instruments are only made by Messrs. Johnson & Phillips. A more serious matter for criticism is the section on incandescent lamps, which is very much out of date; the osmium lamp is mentioned as if it was still a commercially practical lamp, the tantalum as quite a new lamp, and no reference is made at all to the tungsten lamp.

Electricity for Everybody: a Popular Handbook. By R. Borlase Matthews. 314 pp. 4½ in. by 7¼ in. Illustrated. (London: Electrical Press.) 6s.

From the title of this book it is a little difficult to tell quite what its objects are. We are rather led to expect at first a sort of "Every man his own lawyer"—or rather electrical engineer—attempting to enable the man in the street to dispense with the expert, but a closer perusal of the contents reveals the fact that the "everybody" to whom the book is addressed is chiefly the would-be central station canvasser. Information of the class that should be at the ready command of those connected with the business side of electricity supply is collected and presented in a readable and well-arranged form, including, besides the strictly electrical, some most amusing hints on approaching prospective consumers. There is, however, a great deal that will be of use to the prospective consumer, who can think for himself, especially in the section giving approximate data as to power taken by different tools, &c., and it is not too much to say that few people of any class will lay down the book without their views having been broadened as to the capabilities of electricity, and their knowledge of how to apply it to the best advantage increased.

Examination Questions on Electrical Engineering set by the City and Guilds Institute, 1900-1908. By "A Certificated Teacher." 95 pp. 4¾ in. by 7¼ in. With illustrations. (London: S. Rentell and Co., Ltd.) 1s.

As its title implies, this little book is a compilation of the elementary and ordinary grade examination questions on electrical engineering set by the City and Guilds Institute from 1900 until 1908, with the answers thereto. The answers are much fuller than it would be possible for a student to give at an examination. It is proposed to make the publication an annual one, bringing the examination questions up to date.

Tube Railway Platforms.—The platforms of the Central London Railway are being converted from wood to concrete on the recommendation of the Board of Trade in the interests of the greater safety of the travelling public. The recommendation in question was made as the result of the fire at the Moorgate Street station of the City & South London Railway, and the platforms at 12 stations of that company are being reconstructed in the same way.

Electric Smelting in Canada.—According to our Canadian contemporaries published in London, arrangements are being made for the establishment of an electric smelting plant in Canada, in connection with the Sault Ste. Marie iron and steel industries, where a number of furnaces similar to those now in successful operation in Sweden are to be installed. A second electric smelting enterprise, involving the investment of several million dollars, is also contemplated for the treatment of iron ores on the Ottawa River at Chat's Falls, where a power site has been secured by a company having its headquarters in Ottawa.

A NEW TURBO-PUMP

THE facility with which centrifugal and turbo-pumps running at a high speed can be coupled directly to electric motors so as to form compact self-contained pumping sets has led to a large increase in the demand for this class of machinery, both for high lift purposes as often required in mining, and for such work at lower heads as for circulating pumps for condensing plants, &c. To meet these requirements, Messrs. Willans & Robinson (Rugby) have developed the form of pump shown in the accompanying illustrations, and known as the Willans-Victoria Turbo-Pump. These pumps, which were designed by Mr. J. Orten Böving, are fully standardised, so that cheapness as well as interchangeability of parts is obtained, and are manufactured for lifts varying from the lowest up to 2,000 ft.

A fruitful source of trouble in some high lift pumps is the pressure gland at the delivery end. To avoid undue leakage these glands have sometimes to be screwed up very tight, and the pressure of the packing material on the shaft is apt to cause considerable wear, and loss of efficiency. This trouble is absent in the Willans pump, because no pressure stuffing box is required, as only low pressure exists in the end chamber behind the last diaphragm. The stuffing box at the suction end is water sealed, and as it has only to hold tight against one-tenth of an atmosphere, there is no necessity to set the packing hard against the shaft. Nor is any thrust bearing needed, as the end thrust is balanced by a special patented device, which automatically adjusts itself for changes of head and output while the pump is running, and for any wear that may take place in the impellers. The bearings are separated by a gap of an inch or two from the packing, so that it is impossible for any grit, mud,

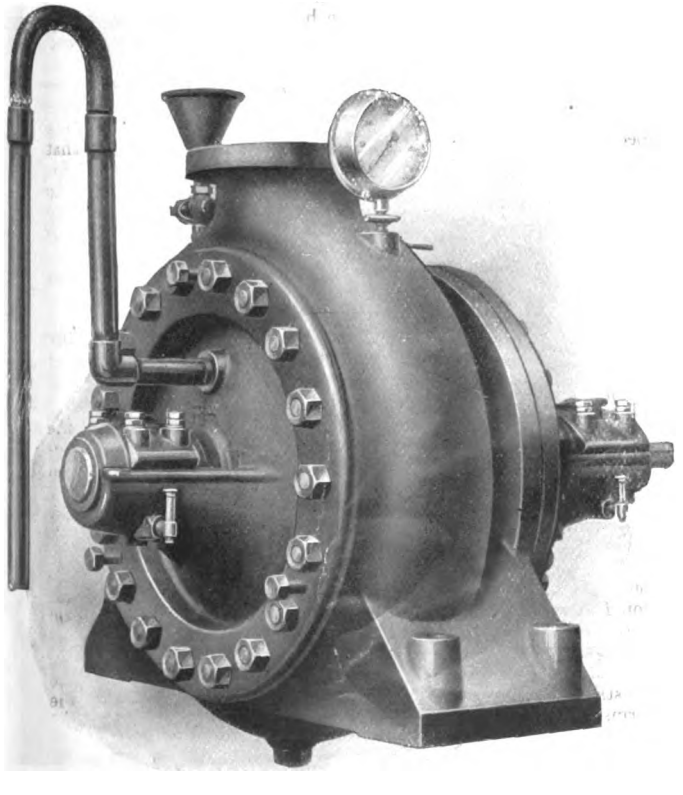

FIG. 2.—GENERAL VIEW OF PUMP.

or water to enter. The end covers are cast in one piece with the bearings, and fit cylindrically into the centre casing. It is therefore impossible for any part to get out of alignment if the pump is dismantled. The bearings are usually arranged for ring lubrication, but in the case of sinking pumps the bearings can be supplied with oil under pressure. The central casing is of cylindrical bore, and the guide wheels and diaphragms fit cylindrically into the casing. The dismantling and reassembling of the sundry parts is therefore an extremely easy matter, as they only have to be pushed in one after the other from the open end. It is therefore impossible even for an unskilled

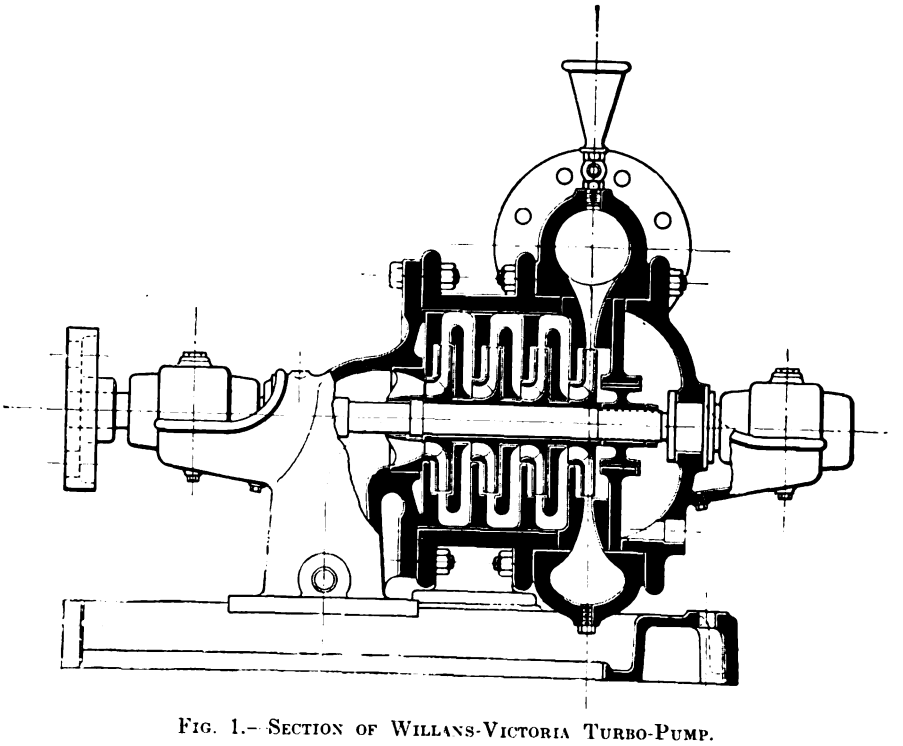

FIG. 1.—SECTION OF WILLANS-VICTORIA TURBO-PUMP.

erector to get the parts out of true alignment, as is sometimes liable to happen with pumps built with separate sections for each stage. The impellers and guide wheels are all made of special bronze, and the inner surfaces of the impeller and guide wheel channels are carefully finished throughout either by machine or by hand, so that the water during its whole passage through the pump from the first impeller to the delivery casing never comes in contact with any rough surface. The finish of these parts is an important point, as experience has shown that the wheels treated in this way have a much longer life when dealing with gritty or muddy water than those having unfinished channels. The central casing of the pump is in all cases lined with special bronze, so that no acid or gritty water comes into contact with the casing itself at any point. It is stated that in consequence of these and other points of careful design and manufacture very high efficiencies are being obtained in practice.

Caracas Telephone System.—The telephone system of the Venezuela Telephone & Electrical Appliances Co., a British-owned concern, has been converted to the central battery system, so that Caracas now possesses a thoroughly modern telephone service.

Telephone Service in Italy.—The Italian estimates of expenditure for the financial year 1908-9 show an increase of £704,071 in the sum allotted to the Ministry of Posts and Telegraphs. Of this, £364,831 is for the purchase of telephone systems by the State, and £339,240 for the improvement of the telephone service.

The Civil and Mechanical Engineers Society.—Mr. W. Noble Twelvetrees delivered his presidential address before the above society last Thursday. Choosing as his subject the union of engineering societies, he referred to the scheme for amalgamation of their own society (founded in 1854) with the Society of Engineers (founded in 1859). It is proposed that the new organisation be incorporated under the title of the Society of Engineers (Incorporated), but the sanction of the members of both societies has first to be obtained. The president expressed the hope that the scheme would see a successful issue and outlined some of the changes involved, which would, he said, be to the great improvement of the status of both societies. A new class of Fellows was proposed in addition to members and associate members for those of special distinction. Speaking generally on the advantages of combination among bodies with like objects, he took as examples the societies allied to the Royal Institute of British Architects, and those which were brought together by the Institution of Mining Engineers. He hoped that in the future some such linking up of unattached provincial organisations might be found possible in connection with the new society which was now under consideration.

CATALOGUES AND PAMPHLETS RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

MOTORS AND CONTROLLERS.—Lists recently issued by the Electrical Co. (121-5 Charing Cross Road) include those devoted to three-, two- and single-phase open and enclosed induction motors up to 6 h.p., with and without slip rings, and lift controllers. The latter contains prices of component parts for complete control equipments for lifts with lever, rope, or press-button control, including several types of reversing controller for both continuous and alternating currents.

SWITCHES.—We have received two new leaflets from Messrs. A. P. Lundberg & Sons (477-487 Liverpool Road, N.). One of these deals with the "Presto" 5-ampere tumbler switch with porcelain insulation throughout, which has been brought out to satisfy the demand for a cheap surface-type switch with metal covers only. The other contains particulars of the latest patterns of combined switches and three-pin wall plugs, together with other combinations of switch and plug for various special purposes, with diagrams explaining their uses.

FUSE BOXES AND SEALING TROUGHS.—A large number of patterns of house service fuse box are described and illustrated in a new catalogue from the Reason Manufacturing Co. (Brighton). Special boxes have been designed for all ordinary form of cable and wiring systems, with which plain, porcelain bridge, or enclosed fuses can be used. The range covers

Reason Fuse boxes and Sealing Trough.

single and multiple way boxes and double-pole boxes for various methods of connection. The pattern illustrated here consists of a pair of separate pole boxes suitable for pressures up to 250 volts, with a simple form of sealing in box for twin service cable. Similar arrangements are made for three-core, concentric, and triple concentric cables, and split as well as solid troughs are supplied.

TELEGRAPH AND RAILWAY SIGNALLING APPARATUS.—A booklet from Walters' Electrical Manufacturing Co., Ltd. (Kensal Road, W.), contains a number of illustrations of the company's works which are devoted to the manufacture in large quantities of telegraph, railway signalling, and similar instruments. Attention is also drawn in a leaflet to a new design of one-wire three-indication block instrument manufactured under Mc Ge and Powles' patents.

DIESEL ENGINES.—We have received from the Maschinenfabrik Augsburg-Nurnberg A.-G. (London address, "M.A.N.," 219 Caxton House, Westminster, S.W.) three leaflets relating to Diesel Engines, of which over 1,500 have been made by the company since the original experiments at the Augsburg works from 1893 to 1897. One of the leaflets gives a full illustrated description of the ordinary vertical moderate speed Diesel engine, such as is well known. This pattern is listed in sizes up to 220 h.p. per cylinder. The other pamphlet describes the newer enclosed high-speed engine of much more compact design and lower cost for its power. This interesting class of engine includes a number of sizes ranging from the 50 h.p. two-cylinder machine running at 375 r.p.m. to the four-cylinder engine giving 1,000 h.p. at 187 r.p.m.

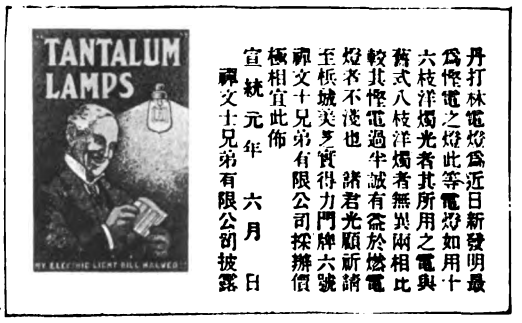
CONDUITS.—Simplex Conduits, Ltd., in issuing the twelfth edition of their conduit list, have extended its utility by binding together sections relating to Simplex conduits and accessories, Simplex flexible system of wiring, distribution boards, enclosed fuses, and watertight fittings for factories, mills, &c. Some reductions in prices are noticeable, and one or two new fittings have been introduced. Among these is the large junction box for main cables, illustrated here. The watertight joint in these boxes is effected by means of a rubber insertion, and the cover is provided with an overlap, and held down by four screws passing into external lugs. Special interiors are manufactured

Simplex Junction-box for Main Cables.

for use in connection with these boxes, made up of $\frac{3}{4}$ in. slate; bus-bars of ample capacity are mounted on separate slabs, divided by a central fillet, and provided with sweating sockets. A further feature is the introduction of spacing saddles for use on surface installations where moisture is present, and where a clearance between the wall and the conduits and fittings is desired. These are made of enamelled steel, and the tubes are sprung into them; when in position, the conduits are raised on two shoulders provided. A new design of watertight "push-on and pull-off" switch fuse has also been introduced.

THERMAL STORAGE.—We have received a booklet entitled "Economy in Steam Raising," which describes the Halpin patent system of thermal storage, the sole licensee for which for England and the Colonies is now Mr. P. J. Mitchell (Caxton House, Westminster, S.W.). Particulars and illustrations are given of several installations where the system is in practice, and interesting curves are reproduced showing the economy attributed to the equalisation of the boiler load, obtainable particularly in electrical generating stations.

OSRAM LAMPS.—The accompanying illustration represents the latest of Mr. John Hassal's productions in the way of metal filament lamp show-cards, and certainly one of the most effective. It brings out in a striking way the most important field of the Osram lamp in putting cheaper illumination within reach of the most modest household. The position of the cat in the left hand corner should be particularly noted.



New Osram Lamp Show-card.

ELECTRIC RAILWAY SIGNALLING.—A pamphlet from the McKenzie, Holland, and Westinghouse Power Signal Co., Ltd. (58 Victoria Street, Westminster), contains a reprint of an article in a railway contemporary, describing the "all-electric" power signalling and interlocking equipment founded on the Taylor system, which the company have installed at Yarnton Junction on the Great Western Railway. All the points, &c., are worked by electromotors without friction clutches, as electrical means of protection against excessive current due to jambing have been devised. The signals are operated by a motor having a combined electric clutch gear and holding-off coil. When the arm is at an angle of 60 degrees a snap switch circuit

Digitized by Google

controller cuts out the motor and switches in the hold-off coil—thus the signal is held off. The signal lever being put to normal the holding-off coil is de-energised, the clutch released, and the signal goes to "danger" without rotating the motor or its gear wheels, thereby eliminating the danger attendant upon gear wheels jambing and holding the signal off. The shunting signals are of the dwarf type, with collapsible arms, and have white front lights for the night danger indication. They are operated by a solenoid, and are provided with a lock to prevent the arm being pushed off by hand. For this trial installation a 10-h.p. oil engine and generator is used in conjunction with two batteries. The voltage used in the installation is 120, the points taking four amperes and the signal two amperes.

TANTALUM LAMPS.—The familiar face of the satisfied consumer, whose electric light bill has been halved by the adoption of tantalum lamps, is likely to become as well known in the

CHINESE TANTALUM LAMP POSTCARD.

Far East as at home through the medium of the interesting Chinese postcard, reproduced herewith, which Messrs. Siemens Brothers Dynamo Works have added to their already long list of foreign adaptations of this design.

TIME SWITCHES.—One of the latest features to be added to the series of automatic time switches made by the Reason Manufacturing Co. (Brighton) is an electrically worked self-winding attachment actuated by an ingenious arrangement of solenoids. This is described in a booklet just issued, together with other features of the switches, such as the thermostatic cut-out which protects the winding solenoids from sudden rises in voltage, and the "Sunday" attachment for arresting the action of the switch one day in the week. Several patterns of change-over switches are made, as well as ordinary single- and double-pole apparatus.

ELECTRIC CRANES, &c.—We have received from Messrs. Royce, Ltd. (Trafford Park, Manchester), a collection of interesting reproductions from photographs of electric cranes, capstans, winches, hoists, and other machinery made by them, mostly shown in actual operation. This has been prepared as a temporary substitute pending the completion of the fifth edition of their illustrated catalogue, which is being enlarged and revised.

INTERPOLE MOTORS AND DYNAMOS.—A new illustrated pamphlet issued by Messrs. Bruce Peebles & Co., Ltd., of Edinburgh, deals with large continuous-current dynamos and motors of the open type. These machines are fitted with interpoles, which, in conjunction with the laminated pole tips, render them sparkless. Complete information with regard to efficiency, weight, and dimensions is given, together with a general description of the mechanical and electrical features. The standard machines are listed up to 1,500 h.p. and 1,100 kw.

TUNGSTEN AS A "VALVE" ELECTRODE

AN original communication by Mr. L. H. Walter, announcing the discovery that tungsten must be added to the list of metals which show the effect known as "valve action" when used as electrodes in electrolytic cells, has been accepted by the Institution of Electrical Engineers.

The effect was first observed when making experiments with a sealed-in tungsten lamp filament used as anode in a form of electrolytic detector with sodium chloride solution as electrolyte. It was noticed that on raising the polarising potential difference, the characteristic "boiling" or hissing of the detector, due to evolution of gases, was entirely absent; and the similarity in the behaviour to that of the tantalum point-electrode suggested that there must exist, in this case also, a marked asymmetric effect.

Experiments with a somewhat larger anode with direct current showed that the phenomenon was not merely an asymmetric effect due to the difference in the areas of the electrodes, but was a real "valve" effect.

The behaviour of tungsten in sulphuric acid of considerable strength with an applied potential difference of 90 volts was specially investigated, as, were it possible to make use of this electrolyte in rectifiers with tungsten anodes, the dimensions of the cells would be able to be much reduced as compared with those of the cells usually employed, since the conductivity of the acid is so high. For this reason, although it appears probable that, as in the case of other metals, the critical voltage is notably higher in less active electrolytes, the first experiments were confined to the examination of the behaviour with sulphuric acid and with potassium bichromate.

In the representation of the results, for showing the sealing-off property of the anode, the residual current through the cell, in milliamperes after 20 seconds, is plotted as ordinate against the potential difference across the cell as abscissa. The effect of the temperature of the electrolyte upon the leakage current in sulphuric acid is shown in Fig. 1. The full curves give the

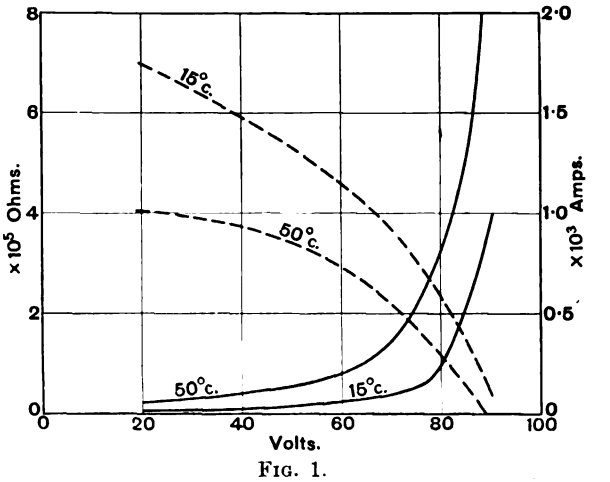


FIG. 1.

normal current at 15° and at 50° C. respectively, the dotted curves the respective resistances. These latter indicate where the critical voltage must lie (zero resistance) without it being necessary actually to break down the film. The usual behaviour, namely, that the leakage current is greater at higher temperatures, is observed, but the critical voltage is very little altered.

The effect of cutting off the current for shorter or longer periods can be seen in Fig. 2 for three different applied voltages,

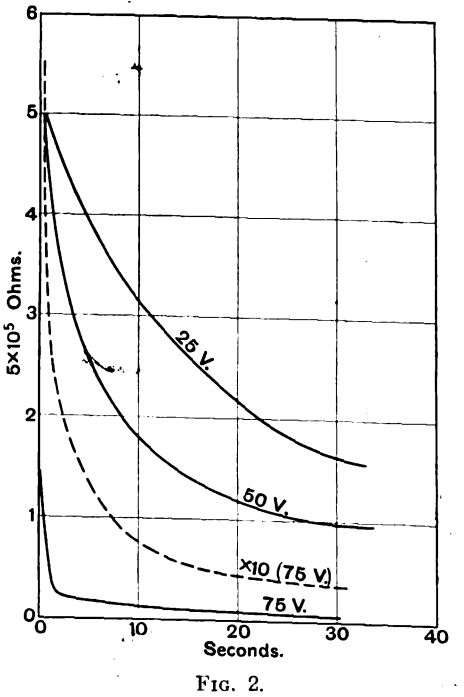

FIG. 2.

viz., 25, 50, and 75 volts, also in sulphuric acid. The points of the full-line curves which lie on the vertical axis show the normal resistances of the cell; the other points give the resistances plotted from the currents observed on remaking the circuit after the current has been cut off for times up to half a minute. At 25 and up to 50 volts it will be seen that the decrease of resistance of the anode film, though fairly rapid, is of a different order from that which occurs at 75 volts. It is interesting to observe that if the curve for 75 volts is reproduced with ordinates all multiplied by ten, the curve so obtained (dotted curve of Fig. 2) is very similar in shape to those for the lower voltages. A few experiments with alternating currents showed that, using new tungsten anodes which had never previously been "formed," a direct current was at once obtained on switching on the alternating supply, the applied voltage being 25 volts and the rectified current being 0·25 ampere.

GERMAN ELECTRICITY SUPPLY STATISTICS

THE statistics relating to electricity supply in Germany for the years ending April, 1906, and April, 1907, which were published in the *Elektrotechnische Zeitschrift*, were summarised in Electrical Engineering, April 25th, 1907, Vol. I., page 733, and April 9th, 1908, Vol. III., page 554, respectively. No statistics were published for the year ending April, 1908, but this year the Verband Deutscher Elektrotechniker has arranged for their publication, and the following notes are taken from a summary of the statistics by G. Dettmar, the secretary of the Verband, which appears in the *Elektrotechnische Zeitschrift* of Sept. 30th.

There were on April 1st, 1909, in Germany, 1,978 central stations in operation, as against 1,526 in April, 1907, an increase of 452 stations in two years. Some 64 stations were either in course of construction or about to be commenced on April 1st, 1909. The total kilowatts connected to all the electricity works in April, 1909, were as follows:—Incandescent lamps, 670,418 kw. (486,828 kw. in April, 1907); arc lamps, 129,011 kw. (89,456 kw.); motors, 896,910 h.p. (582,862 h.p.); traction motors (supplied from 151 stations), 286,910 h.p.; heating and cooking apparatus, 37,721 kw. This makes a total of 1,872,592 kw. in 1909, as compared with 1,100,861 kw. in 1907, and 829,541 kw. in 1906.

The following table gives an idea of the extent to which the different systems of generation and distribution are in use.

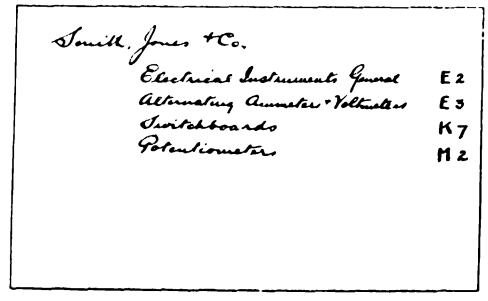
Systems of Supply.

System.	Number of stations.	Kw. capacity of machines.	Kw. capacity of accumulators.
Single- and two-phase	47	18,463	338
Three-phase	183	186,428	1,367
Continuous current.....	1,543	261,525	101,052
Combined A.-C. and D.-C. ...	205	521,448	70,988

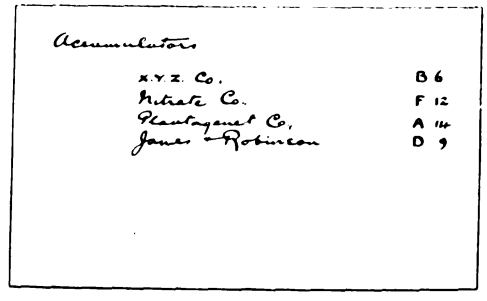
According to the returns obtained from the 1,978 electricity works in operation, there is no competing gas supply in 1,010 cases. In only 351 cases was the question as to the existence of a gas works actually answered in the affirmative, no reply being obtained from the remaining 617 works. There are 19 stations with a capacity of over 10,000 kw.; 21 with between 5,000 and 1,000 kw. capacity; 53 between 2,000 and 5,000 kw.; 71 between 1,000 and 2,000 kw.; and 123 between 500 and 1,000 kw.; the remainder are under 500 kw. capacity. Of the 93 stations of over 2,000 kw. capacity, 50, or over half, are under municipal or State control.

With regard to the distribution systems, 1,962 stations have sent in returns, and of these 133 had exclusively underground cable networks, 1,448 had exclusively overhead networks, and 381 had distributing networks of both kinds. It appears that 292,099 meters for lighting only and 75,973 meters for power only were installed, while 269,809 were installed for lighting and power combined. Of the total number of stations, 713 employ steam engines only; 177 use water-power exclusively; 348 have combined steam- and water-power plant; 294 employ gas and oil engines; 36 have only transforming machinery; and 410 use miscellaneous engines. There are only 13 stations that have been in operation for over 20 years.

The Brazilian Telegraph System.—Including the federal trunk line telegraph (18,207 miles), the State line in Rio Grande do Sul, the railway telegraph lines, the subfluvial cable up the Amazon, and the foreign cables along the coasts, it is stated in an American Consular report that the total telegraph lines actually in service amount to 36,119 miles. The telegraph business in 1907 amounted to 27,810,407 words, and in 1908, to 38,794,780 words.



Lectures on Aeronautics.—It is announced that through the generosity of Mr. Patrick Alexander a special course of lectures on aeronautics is to be given at the East London College by Mr. A. P. Thurston. Theoretical as well as practical consideration will be dealt with, and the course, which is to commence on Monday, October 18th, at 7 p.m. will be followed by drawing office practice in the design and construction of aeroplanes.



Reduction of Current Consumption of Tramcars.—Some years ago, meters were placed on a number of tramcars in Berlin in order to see if that would lead to more efficient control by the drivers, and by the end of the year 1907 over 250 meters were in use. Since February, 1908, however, all these have been removed, and clocks installed in their stead. The balance wheels of these clocks are released by an electromagnet when current is taken from the overhead wire, so that the clocks register the current-hours. The least current consumption has been proved to correspond with the least number of current-hours, and the registering of the total time the current is on is said to have advantages over the registration of the total energy consumed. The magnet winding is put in parallel with the controller, and the clock case earthed.

THE INDEXING OF CATALOGUES

ON a recent visit to the Electrical Standards Laboratory of the Board of Trade, we observed the method of dealing with catalogues and price-lists. Mr. Trotter informs us that he is indebted to Mr. G. H. Baillie for the system, which is that adopted at the offices of Messrs. Swinburne, O'Gorman & Baillie. The collection is a small one, containing between 150 and 200 catalogues, in addition to about 3 ft. run of bound books. The main principle is that alphabetical order of name or of subject is ignored, and the catalogues are grouped solely with reference to height. No attempt is made to keep together the various catalogues of one firm if they vary in height. The absurd want of uniformity of catalogues ceases to be a difficulty, and indeed becomes a convenience. The largest size is just under 13 inches. The space between two shelves, 13 in. apart, is divided into pigeon-holes each 3½ in. wide. Stout millboard is used for the divisions, and a segment is cut out of the front edge of each to facilitate the handling of the catalogues. Each pigeon-hole is lettered, and each catalogue has a letter and number. The letters and numbers are about 1½ in. high, and are impressed on the top left-hand corner of the cover by rubber stamps, unless the cover is of a very dark colour, when a paper label is fastened to receive the impression. Each pigeon-hole contains about fifteen catalogues. Those in the C hole are about 11 in. high; those in the M hole are about 7 in. high.

A card index is of course used, and consists of an alphabetical and of a subject index. No special ruling is used. The following are imaginary specimens:—

Leaflets and loose sheets are kept in spring files. When a catalogue is removed for reference its place is kept by a wooden paddle. When a catalogue superseding previous ones is received, it is stamped with the letter and number, and the old one is destroyed.

New Motor Coaches for the Blankenese-Ohlsdorf Single-phase Line.—It will be remembered that the Allgemeine Elektricitats-Ges. has recently constructed 25 new motor coaches for this 6,000-volt, single-phase railway, which runs through Hamburg. The number of cars now in service is 85, and an order for a further 25 cars has just been placed by the Prussian railway authorities. These new cars, which are to be delivered before June next, will be electrically equipped, partly by the Allgemeine Elektricitats-Ges., and partly by Siemens-Schuckert-Werke. The new design is somewhat different from the original A.E.G. 1906 type, the chief alteration being the substitution of two 180-h.p. motors for the three 115-h.p. motors.

Telephonic Time Signals.—A German contemporary describes an arrangement which has been instituted by the observatory of Hamburg for transmitting time signals which can be received by any subscriber to the telephone network in the neighbourhood by obtaining connection to the appropriate number. A signal is transmitted every minute throughout the day and night, producing a sound like that of a syren, which is continued for five seconds. This signal is followed by a further signal resembling a bell every fifth minute. The transmitting clock is provided with a suitable series of contacts, and is controlled electrically by the standard clock at the observatory.

ELECTRICAL WORK IN MINES

Prosecution of Mine Managers.

At the Sheriff's Court at Hamilton, Lanarkshire, on the 12th inst., before Sheriff Thomson, Mr. Andrew Salmond, manager of Ferniegore No. 1 Pit (owners, Archibald Russell & Co., Ltd.), was prosecuted by the Crown under the Coal Mine Regulation Act of 1887 and the Special Rules for the Installation and Use of Electricity in Mines.

The Procurator Fiscal for Lanarkshire, Mr. Wm. Thomson, acted for the prosecution, and the Hon. Wm. Watson, K.C. (instructed by James Andrews, of Mitchell, Johnson & Co., Glasgow), for the defence.

There were two charges, the first being that the Special Rule No. 7, applying to an earth detector, had not been complied with, and that Special Rule No. 30, applying to the construction and maintenance of trailing cables, had not been complied with.

The clause in question reads as follows :—

Trailing cables for portable machines shall be specially flexible, heavily insulated, and protected with either galvanised steel wire armouring, extra stout braiding, hose pipe, or other effective covering. Trailing cables shall be examined at least once in each shift by the person in charge of the machine, and any defects in them promptly repaired.

The first charge was withdrawn, and the second was proceeded with.

Mr. J. M. Ronaldson, Inspector of Mines for the West Scotland district, stated that he visited the colliery on June 28th, the day after the accident, and again on July 1st, in company with Mr. R. Nelson, H.M. Electrical Inspector of Mines. They saw the coal-cutting machine, and the trailing cable used in the Virtuewell seam in which the explosion took place. The outer covering of the twin cable in question was of leather (spliced); this was found to be in order for work of its length, but in several places the outer covering of leather and the jute packing had been removed by some means, so that the rubber insulation of the twin wires was exposed. In his opinion the cable was not in the condition prescribed by the Regulations, and appeared to have been defective for some time.

There were two or three exposed places, the worst being about 2 ft. long. The twin cable could be separated by the hands quite easily. The cable was in two positions when he examined it.

Under cross-examination, Mr. Ronaldson stated that in his opinion the cable covering would only be destroyed gradually unless dragged through sharp debris, or caught under fall of roof. He could not say whether or not covering would creep if completely severed, or whether braiding was put on by tension. He was quite satisfied in the case in question that the wear had been gradual, as the edges were jagged and frayed. The general appearance of the cable (which was seen to be partially coiled), and the mine in the immediate vicinity, precluded any chance that the cable might have been damaged, to the extent it was, by flying debris.

A long discussion followed on the exact position of the defects in the cable, the position of the cable after the accident, &c. So far as witness could see, the force of the explosion had been less towards the working face of the coal wall than away from it, and consequently there would not be much debris flying in that direction. If it had been, the cable would have been found in a much less orderly state.

The Sheriff asked what, in Mr. Ronaldson's opinion, caused the explosion. Mr. Ronaldson replied that he could only surmise that it had been due to a naked light or a spark, and as there was no evidence of the former being present, and there was evidence of a defective state of part of the electrical plant, he had come to the conclusion that it was probably due to the latter.

In reply to the prosecution, Mr. Ronaldson stated that the signs pointed to the falls of roof being much more violent some distance away than they were near the coal-cutter and gate-end box. The cable was coiled up along the working face. The distance of the gate-end switch to the coils of cable referred to would be about 30 to 40 yards, and there was more cable out than was needed to reach the machine in the position it was found in.

The next witness was Mr. Robt. Nelson, H.M. Electrical Inspector of Mines. He visited Ferniegore No. 1 Pit on July 1st in company with Mr. Ronaldson, and examined the trailing cable used with the coal-cutter in the Virtuewell seam and found it defective. He explained to the Court that a trailing cable under the Regulation usually consists of two copper cables covered with rubber insulation, then cotton braiding, and in addition soft packing and a rope or leather covering for mechanical protection. In three or four places he found the rope or leather covering missing. The parts were all at least 6 in. long at the worst parts. Cable exposed without mechanical covering in this way could easily become abraded by fall of roof. The imprint of a man's boot or the impact of a hutch and the result might be a spark or shock, according to the conditions. The breaking of the cable when alive would produce a spark. If the covering became abraded it was essential that it should be repaired very promptly. He judged that the defects he saw were very old—several days, or possibly weeks. He did not think that the cable had been damaged by explosion, as it was unlikely that the cable would have been affected in a few places only. He could not give distance of faults from gate-end box, and saw no evidence of falls of roof in the immediate vicinity of the plant he was examining. The junction of the cable was near the coils referred to, but he could not be sure as to whether it was on the coal-cutter side or the gate-end box side. From what he saw he gathered that the man was extending the working cable and was inserting a fresh length. So far as his recollection went there were defects in both parts of the cable.

Cross-examined, Mr. Nelson said he assumed that portion found on machine had been in use, and coiled section was the new length the machineman was putting in. He had confined himself to an examination of the electrical plant, but had an idea of the general conditions. He thought it probable that hard bodies were lifted and thrown about by the explosion, but if these hard bodies had abraded the cable the cuts would have been clean—this he had noticed before; but in this case the leather covering, &c., was frayed and dirty, as though it had been dragged along the coal floor. He had had considerable experience of electricity in mines before taking up his present position, and since doing so had reported on three explosions. The construction of the cable was in accordance with the rules; it was the maintenance which was at fault.

Further evidence was heard, and finally Mr. Salmond was acquitted, as negligence was not considered to have been proved, although the Sheriff thought that the cable was probably defective.

In the Dunfermline Sheriff's Court last week, a case was mentioned in which the manager of the Fife Coal Co., Mr. C. A. Carlow, and the certificated manager of the Foulford pit of the company, Mr. W. Richardson, are being prosecuted for allowing electrical apparatus to remain in such a condition, between April 1st and August 7th, 1909, as not to conform with the special regulations relating to electrical work in mines. On behalf of the company, objection was taken to the prosecution on the ground that the general manager did not hold the office mentioned in the complaint. He was managing director of the company. The letter of complaint, it was argued, did not relate to any specific pit, but to the whole of the 41 pits of the company, and counsel for the company characterised the action of Mr. Atkinson, H.M. Inspector of Mines for the district, as one calculated to get behind the spirit of the regulations. They could not get any definite intimation from the Inspector as to what he really required, and no courtesy seemed to be extended by the Inspector. The Special Rules clearly meant that some attempt should be made to meet each other before criminal proceedings were taken. The company were most anxious to do everything for the safety of the men, and had spared no expense in this direction in the past. Judgment on this preliminary point will be given to-day.

The Home Office Committee.

At a meeting of the Council of the Newcastle and Gateshead Chamber of Commerce last week it was urged that manufacturers of electrical machinery should be represented upon the Special Committee which is to be appointed for considering the existing regulations relating to the use of electricity in mines.

The Dangers of Electricity in Mines.

At the Conference last week of the Miners' Federation of Great Britain, reference was made to the West Stanley disaster. Mr. W. E. Harvey, M.P., stated that it was conceded on all hands that the introduction of electricity into mines had created a new danger which had to be very closely watched. He hoped that as a result of the Royal Commission on Mines there would be a new Mines Act providing more adequately for the saving of life. It was also strongly urged that the present staff of inspectors is very inadequate. A resolution calling for the prohibition of the use of electricity in dry and dusty mines was withdrawn, the Home Secretary having stated that this question will be considered by the Special Committee.

At the annual meeting of the South Staffordshire and Warwickshire Institute of Mining Engineers, which was held in Birmingham on Tuesday, Mr. Hugh Johnstone, the President, and H.M. Inspector of Mines for South Staffordshire, referred to the use of electrical apparatus in mines. He was of opinion that mineowners and managers should weigh carefully the advantages and disadvantages of the use of electrical apparatus, which might be under the control of persons who could hardly be regarded as experts, before introducing it into a fiery or dusty mine. He believed that many of those who read the reports of the official inquiry into the Hamstead disaster entertained a great suspicion as to the part played in it by the electrical

Digitized by Google

apparatus. In any case it was clear that the utmost care, and the use of every precaution was called for on the part of owners, officials, and workmen alike, if the present position in regard to explosions was to be improved upon.

We have received the following letter on this subject:—

To the Editor of Electrical Engineering.

Sir.—*Re* letter signed "H. J. Fisher" in your issue of the 9th ult., containing the words:—"The fact, also, that in these old installations sparking and arcing were quite common, even in dry and dusty places, and the wretched state in which these installations were left, *points to the danger of explosion from electrical causes not being so great as is imagined.*" Now, sir, I contend that if sparking and arcing did take place, it was only when there was no explosive gas or coal-dust in an explosive condition hanging around, or this agitation would have been a little ancient.

We know that coal-dust in suspension can be exploded, and the sooner the above-mentioned installations are abolished the better, as the spark or arc plays the culminating part in an explosion.

D.C. and slip-ring motors especially, when working at the face, should be in competent hands as regards the running and maintenance, and these men should be able to appreciate a spark—not to mention an arc—to its full value. It is no use making a gate-end panel with gas-proof lids, if the bushing of the holes through which the leads pass is inefficient.

Yours faithfully,

"Pitman."

Gateshead, October 4, 1909.

A Minister of Mines.

A resolution calling upon the Government to appoint a Minister of Mines was carried at the Miners' Federation Conference.

Telegraph Traffic.—There are no interruptions to be recorded this week. A new cable has been laid by the Persian Government from Bunderabbas to the island of Henjam, just opposite to the former place, and that the line via El Arich was working again as usual on the 11th inst. A reduction has been made of the rate to Manitoba to 1s. 5d. per word, and perhaps it is also a sign of progress that the Great Northern Telegraph Company can accept as from the 15th inst. Press messages via Kiachta and Vladivostock exchanged between Germany, Austria, Denmark, France, Spain, Great Britain, Hungary, Italy, and Norway, and Japan, Corea, China, Hongkong, and the Island of Formosa, as well as between Spain, France and Great Britain and the Philippine Islands at rates charged by the Eastern Telegraph Company. The cables enumerated in our last issue as being down have not yet been repaired.

Water Power Transmission Scheme.—It is proposed, says the *Electrical World* of New York, to erect an electric generating plant on the Colorado River at what is known as The Needles, situated about 25 miles south of Powell, Ariz. Colonel C. E. Apponi has secured the water rights to a strip of the river territory five miles in length at the first rapids, and it is at that place the plant will be situated. A complete survey of the site has been made, and a syndicate of Milwaukee has been interested. The initial plant will have a capacity of 30,000 h.p., and a number of transmission lines to supply towns and industrial plants within a radius of 170 miles of the generating plant will be erected. There are also many mines within the proposed radius. A large dam will be constructed, a storage reservoir will be built, and a system of canals will be utilised for irrigation purposes over a large area of land. The estimated expenditure is about £400,000.

New Pattern of Arc Lamp.—A new pattern of enclosed arc lamp which has just been introduced by the General Electric Company of America is described in the *Electrical World*. Two upper or positive carbons, 6 mm. in diameter and 305 mm. in length, are placed in converging tubes, so that the ends of the carbons are in contact. A weight, bearing down on the top, prevents one carbon from being consumed faster than the other. One lower or negative carbon is used, 9·5 mm. in diameter, and 160 mm. in length. The lower carbon holder is movable in a vertical direction, being attached to a counterweight mechanism through which the action of gravity tends to hold it in contact with the upper carbons. The magnet, acting through a clutch on a rod of the counterweight mechanism, draws the lower carbon downward away from the upper ones. In this way the magnet causes the carbons to strike and maintain the arc, keeping the lower carbon floating at the point of electrical equilibrium. The current density is said to be much greater at the carbon tips than in the case of the standard enclosed lamp, and in consequence the crater is at a higher temperature. A small reflector is placed immediately above the arc. The efficiency is stated to be about 1·25 watts per mean hemispherical candle-power for a 5 amp. 110-volt D.-C. lamp, and the general distribution of light is said to be most suitable for interior illumination. A carbon life of 75 to 100 hours is claimed for a lamp with the above characteristics.

THE "Z" ELECTRIC LAMP PATENT INFRINGEMENT CASE

ON page 685 of our issue for July 29th we mentioned a patent infringement action taken by the "Z" Electric Lamp Co., Ltd., against Messrs. Marples, Leach & Co., Ltd., now the Adnil Electric Co., Ltd. It is unlikely that the action will be heard for some time yet, but in July an application was made before Mr. Justice Warrington in the Chancery Division by the plaintiffs for an order compelling the defendants to give more detailed particulars of their objections to the patent in order that they might the better meet the defendants' case. Mr. Justice Warrington decided that the particulars already filed by the defendants were quite sufficient. The plaintiffs appealed against this decision on Tuesday before the Master of the Rolls (Lord Justice Cozens-Hardy), Lord Justice Fletcher Moulton, and Lord Justice Farwell. Mr. Colefax again appeared for the plaintiffs, and Mr. Terrell, K.C., for the defendants, and the arguments reported in our issue for July 29th were repeated. Lord Justice Fletcher Moulton said that to ask for further particulars than had already been given was really to ask the defendants to indicate in what respects the plaintiffs' patent could be put right.

Export of Electricity from Canada.—It is stated that during last year the total amount of electricity exported by the four companies operating under the Canadian Electricity and Fluid Exportation Act was 359,283,286 units, as compared with 135,075,680 units generated for home consumption. The Canadian Niagara Power Co. exported 221,927,240 units, and generated for home consumption 5,405,760 units. The Electrical Development Co. exported 4,680,500 units, and generated for home consumption 85,515,700 units. The Ontario Power Company exported 131,833,782 units, and the home consumption was 44,150,580 units. The Maine and New Brunswick Power Co. generated for export 841,764 units, and the home consumption was 3,940 units.

Railway Electrification in Chicago.—As a result of the active agitation which has been carried on for some time in favour of the compulsory conversion of all steam railways entering the city of Chicago to electric traction, the City Council have drawn up an ordinance requiring all railways within eight miles of the City Hall to adopt electrical power after January 1st, 1912, in accordance with plans approved by the Commissioner of Public Works. There is considerable opposition on the part of the railway interests, but according to the *Electrical Review and Western Electrician* (Chicago) the city officials consider the legality of the ordinance unquestionable. The ordinance has yet to be reported on by the committee on local transportation, but in the opinion of our contemporary there is every likelihood of its being finally carried.

L.C.C. Contracts and Patent Rights.—One of the terms of the London County Council's contract with Messrs. Mountain & Gibson is that the latter shall indemnify the Council in respect of all claims arising under patent rights. Notice has now been received from Dick, Kerr & Co., Ltd., claiming patent rights in respect of part of certain electrical equipments which have apparently been supplied to the Council by the British Westinghouse Company, Ltd. The latter company, as sub-contractors to Mountain & Gibson, are also supplying the electrical equipments for some stores transport vehicles, upon the terms of the Council's contract with Messrs. Mountain & Gibson. The receiver of the latter firm has asked the Council to accept the British Westinghouse Co.'s indemnity direct against any claims under patent rights in respect of these electrical equipments, so as to absolve him from the stringent provisions of the indemnity clause in the Council's contract, otherwise he states that he will be unable, in view of the claim made by Dick, Kerr & Co., Ltd., to proceed with the contract. The Highway Committee of the County Council have authorised the transfer of the indemnity.

Constant-current Generator.—A new pattern of constant-current generator was described in a Paper read by Herr von Kraemer before the recent annual meeting of the Verband Deutscher Elektrotechniker. The machine is constructed by the Felten & Guilleaume-Lahmeyer Co., and has three exciting windings, a shunt winding, a series winding, and a separately excited winding opposed to the series winding. Normally, the last two windings balance one another, and the machine operates as a shunt generator. Should the load current increase from any cause, the difference in ampere-turns between the separately-excited winding and the series winding opposes the shunt winding, and decreases the generated voltage. If the load current decreases, the surplus ampere-turns of the separately excited winding assist the main shunt winding and increase the voltage. All three windings are arranged on the poles of the machine, which is otherwise of normal design, and the turns and separate excitation are so adjusted that the current is automatically kept constant with varying voltage and external resistance. The machine can be applied to winding for mines, and to rolling mills, and can be used as a booster for charging storage batteries, for arc lamp circuits and searchlights.

THE MANCHESTER ELECTRICAL EXHIBITION, 1908

THE accounts have now been issued of the Manchester Electrical Exhibition held last year, from which it appears that the total expenses amounted to £13,076 (including the special rebate of £66 to members of the National Electrical Manufacturers' Association). The receipts reached the total of £19,393, of which £10,061 was paid by exhibitors for space, £1,133 given by Corporations, and £4,750 taken in gate money and for tickets, the remainder being from various incidental sources. Of the balance of £6,317 remaining, a 20 per cent. return was made to exhibitors, a 10 per cent. return to donors, and, in accordance with agreements, 45 per cent. of the profits was handed to International Trade Exhibitions, Ltd., and 10 per cent. to Messrs. C. S. Northcote and W. Davenport. The sum of £740 then remained, which was distributed as follows: East Lancashire Systematic and Benevolent Institution, £10 10s.; Electrical Trades Benevolent Institution, £365; Manchester Royal Infirmary, £146; Ancoats Infirmary, £109 10s.; and Salford Royal Hospital, £109 10s.

ELECTRICAL EXHIBITION AT HAMPSTEAD

THE second exhibition of electrical domestic appliances organised by the Electricity Department of the Hampstead Borough Council, which was held at the Hampstead Baths, Finchley Road, N.W., last week, was open free to the public, and should do much to encourage the use of electric heating and cooking apparatus in the Hampstead district. Perhaps the principal feature of the exhibition was the effective nature of the stalls erected by local contractors. That of Messrs. E. G. Kellond, of 315 Finchley Road, N.W., was particularly attractive. A number of patterns of "Stellite" heaters were to be seen on this stand, and a long metal heater for placing near draughty windows and in ventilating apertures for warming the incoming air was also shown.

A stand comprising a number of panels to illustrate the O.S. wiring system (see ELECTRICAL ENGINEERING, April 8th, p. 337) had been arranged by Messrs. Siemens Bros. & Co., Ltd. (Caxton House, Westminster). Some detail improvements, including back- and side-entry fittings for "Stannos" wires, and steel protecting plates for fixing over surface wiring in schools, &c., and a complete low-voltage wiring installation on the concentric system with a transformer were also shown. The Hampstead Electricity Department had an inquiry bureau and an exhibition of electric kettles and irons, the latter being shown in operation by a number of employees of the Rosemont Laundry of South Hampstead. The only power exhibit, excluding fan and sewing-machine motors, was a screw-cutting lathe driven by a Fuller single-phase motor running from the Corporation 210-volt, 90-cycle mains. Some electrically driven vacuum cleaners with rotary pumps were exhibited by the British Vacuum Cleaner Co. (Parsons Green Lane, London, S.W.). These included a new portable machine particularly adapted to hotel and club work. A novelty in the way of candle fittings was exhibited by the Lux Candle Co., Ltd. (240 High Holborn, London, W.C.). This comprises a long 14-watt 10-c.p. metal filament candle lamp of plain glass, which is enclosed in an outer glass tube, the lower portion of which is translucent. This arrangement enables one to renew the lamp itself at a comparatively low price. A special short bulb lamp is supplied for adapting to the old type of candle holder, the "Lux" candle tube being placed over lamp and holder so as to give the same effect as a long Lux lamp. The metal filament lamps are supplied for 25, 33, and 50 volts.

Among the heating and cooking appliances exhibited were some examples of the General Electric Co.'s "Archer" system, including the new cheap oven described in ELECTRICAL ENGINEERING, May 20th, p. 462; and some Howard and Cousin patent lamp radiators, the lamp units of which have a contact cap at each end, and a zigzag carbon filament supported at both ends and in the middle. Messrs. Eastman & Warne (Acton Vale, W.) exhibited a number of their flat-irons, in which the heating resistances are enclosed in channels so as to give a large heating surface, and are run at a lower temperature than usual. Thus an 8-lb. iron has 72 sq. in. of interior heating surface and consumes 440 watts. We are informed that a number of irons are in use at Messrs. Eastman & Sons' dye works, corresponding to a load of between 85 and 90 kw. Some hot plates on the same principle were exhibited, and also an electric soldering iron, which can be obtained for any pressure up to 250 volts. Messrs. Purcell & Nobbs (87 Cleveland Street, Fitzroy Square, W.) had a number of their "Electroyl" radiators on view. In these, the resistance-wire heating elements are immersed in oil which circulates in a metal case which heats the surrounding air by conduction only. The apparatus was fully described in ELECTRICAL ENGINEERING, Oct. 29th, 1908, p. 586. Messrs. Gillespie & Beales (Amberley House, Norfolk Street, Strand) exhibited several examples of the Bastian quartz radiators, including the pattern described in ELECTRICAL ENGINEERING, July 8th, p. 631, and also a cheap oven consuming only 750 watts. Some examples of Boyd's patent lamp radiators were also to be seen. These radiators have a hot-air trap above the lamps, which acts as a hot shelf, besides effecting a more equal diffusion of the heated air.

Various designs of lamp radiators of the "Le Radiant" pattern, in which the filaments are of a special metal and run at a dull red heat, were exhibited. A four-lamp radiator of this type consumes 700 to 750 watts. An attractive stand, with a representative collection of "Tricity" cooking apparatus, had been arranged by the Berry Construction Co., Ltd. (Charing Cross House, London, W.C.). Besides the well-known single plate cooker, which works on the transformer principle on A.-C. circuits only, a large stove, comprising one transformer and three heating plates, was shown. These plates are regulated by varying the turns in the secondary heating windings instead of adjusting the primary as in the single plate cookers. Some 300-watt convection heaters on the same principle for ship's cabins were also shown.

Australian Patents.—A deputation from the Patents Section of the London Chamber of Commerce waited upon Captain R. Muirhead Collins, representative in England of the Australian Government, in respect of the new Australian Patents Act. This provides for the compulsory working of patents in Australia, and it was pointed out that, although the Commonwealth was progressive, it would not pay in many cases to build works there. The result would certainly mean an increase in the cost of the goods to the purchaser.

Death from Electric Shock on the L.B. & S.C. Railway.—An assistant linesman named George Younger, employed by Messrs. R. W. Blackwell & Co., Ltd., upon the Victoria-London Bridge single-phase railway, met with his death through touching a 6,500-volt conductor on Thursday. The deceased had climbed to the top of one of the girders to which the live wires are suspended for the purpose of replacing a clip, when he apparently touched the wire and was thrown to the ground. It seems that none of the workmen near the spot were aware that the current was switched on. The officials, however, stated that it was a recognised thing to regard the current as on throughout the day. Medical evidence showed that death was due to electric shock, and a verdict of accidental death was returned.

Cable Explosion in St. Pancras.—An explosion occurred at the St. Pancras Town Hall on Saturday last, and though nobody was injured, several persons had narrow escapes, and considerable damage was done to property. It appears that a fault developed at one point on the distributing system of the St. Pancras Corporation Electricity Department, and was followed by a series of faults all along the main cable route on either side of the generating station. Two or three services were quite burnt away, and on Tuesday morning the work of repairing the various faults was hardly completed. It is probable that the explosion at the Town Hall was due to the ignition of coal gas. Under the floor of the room in which the explosion occurred is an iron pipe containing telephone wires, and this pipe opens into a culvert under the road. It is possible that gas, escaping from a neighbouring pipe, had accumulated in the culvert and telephone pipe, and was ignited by the arcing at one of the faults. The presence of the gas and the above explanation of its ignition are only surmises, however, as the matter has not yet been fully investigated.

The Journal.—The September issue of the Journal of the Institution of Electrical Engineers contains the following Papers read before the London meetings of the Institution, and the discussions thereon:—"The Electrical System of the L.C.C. Tramways," by J. H. Rider; "The Theory and Application of Motor Converters," by H. S. Hallo. The following Papers read before local sections, are also included:—"Extending the Limits of Power Transmission," by A. M. Taylor (Birmingham); "Electric Traction Vagabond Currents," by J. G. and R. G. Cunliffe (Manchester); "The Electrification of Steam-driven Non-reversing Rolling Mills," by W. F. Mylan (Leeds); "Interpole Designs," by W. B. Hird (Glasgow). A translation with introductory remarks of the German standards and regulations for electrical machinery, by N. C. Bridge, is also published (by permission of the Verband Deutscher Elektrotechniker), and also the rules for continuous-current traction motors adopted by the International Congress of Tramways and Light Railways, Milan, 1906 (by permission of the Union Internationale de Tramways, Brussels). The following original communications are also included:—"The Metal Tungsten as Valve Electrode," by L. H. Walter, and "On Magnetic Testing of Iron with Alternating Current," by A. Campbell.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 7th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

19,395/08. **Flame Arc Lamp.** H. J. Jaburg. This is a converging carbon lamp with neither feeding nor regulating mechanism. One carbon has, besides the core and the layer of hard carbon, an outer layer of soft carbon, which is burnt away at a low temperature. This part rests on a stop, and, as it is consumed, allows the two carbons to feed down by gravity. To regulate the arc, an electromagnet is placed in such a position that it forces the arc downwards and lengthens it when the carbons have fed, but allows it to shorten and approach the stop, so as to cause feeding, when the carbons are high and far apart. The use of carbons of oval section is also claimed. Three claims, six figures.

19,485/08. **Driving of Rolling Mills.** British Thomson-Houston Co., Ltd. (*Allgemeine Elektricitäts-Ges.*). In systems in which a motor with a fluctuating load is controlled by regulation of the field of the generator, the current easily rises to heavy values and causes the automatic cut-outs to operate. To prevent this, the present invention provides for an automatic device governed by the main current, which weakens the generator field or strengthens the motor field when the current reaches a predetermined maximum value. This device operates for both directions of the current, and can be arranged to strengthen a differential compound winding on the generator or an over-compounding winding on the motor, by interrupting a short-circuiting shunt to the series windings or by other means. Four claims, two figures.

26,287/08. **Decorative Lamps.** British Thomson-Houston Co., Ltd. (*Allgemeine Elektricitäts-Ges.*) Miniature lamps with single-contact caps at opposite ends are connected together in series by means of short lengths of insulated wire with special sockets to insulate all live parts, and to allow of rapid and safe erection. Four claims, five figures.

605/09. **Anodes for Electrolytic Baths.** Siemens Bros. & Co., Ltd. (*Siemens & Halske Akt.-Ges.*). In the electrolysis of zinc sulphate, sodium chloride and other solutions containing free acid, it is important that the anode shall not be chemically attacked. According to this invention, the anode is formed of a plate of manganese peroxide, produced by heating manganese nitrate in a mould. The plate is soaked in paraffin to prevent absorption of the electrolyte, and the end is coated with lead peroxide to provide a good contact. Five claims.

3,637/09. **Lamp-holder Switch.** E. B. Wright. An ordinary bayonet lamp-holder is converted into a switch-holder by inserting an adapter having a plug portion with pins for inserting in the holder, and a socket to take the lamp. In the plug portion is a switch comprising an insulating disc with spring contacts, which is rotated by means of a handle projecting through slots in the adapter. Six claims, six figures.

4,353/09. **Prevention of Electrolysis by Stray Currents.** H. Geppert. Gas- and water-pipes, lead-covered cables, &c., are protected from corrosion due to stray earth-currents from D.-C. traction systems by arranging a protective circuit entirely separate from the main circuit. The pipes or cable sheaths are connected to the negative pole of a battery or other source of E.M.F., and anodes connected to the positive pole of the same source are sunk into the earth in suitable positions. One claim, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Schweiger [Suspension device for supplying lamps from overhead wires] 15,661/09.

Dynamos, Motors, and Transformers: Boeckel, Grünberg, Krukovski, and Luxembourg [Machines] 20,098/08 and 72/09; Allgemeine Elektricitäts-Ges. [Parallel running of alternators] 17,199/09.

Electric Ignition: Varley, 19,850/08; Hounsfield, 24,759/08; Clarke, 25,788/08; Grant, 14,117/09.

Electrometallurgy and Electrochemistry: Soc. d'Electro-Chimie and Hulin [Production of sodium] 22,824/08; Aktiebolaget Elektrometall [Furnace] 4,553/09.

Heating and Cooking: Cooper, Sharp, and Stevens, 12,562/09.

Incandescent Lamps: Gluhlampenwerk Anker-Ges. [Preventing disintegration of metal filaments] 19,847/08.

Instruments and Meters: British Insulated & Helsby Cables, Ltd., and Bayles [Sealing instrument cases] 20,312/08; Landis and Gyr [A.-C. meter] 27,283/08.

Switchgear, Fuses, and Fittings: Hope [Iron-clad switchgear] 17,461/08; Peck [Relays for polyphase circuits] 20,895/08; Siemens Bros. Dynamo Works, and Thompson [Motor controllers] 23,341/08; Rawlings, Handcock, and Dykes [Fixing switches, ceiling roses, &c.] 25,461/08; Tirrill [Voltage regulator] 28,190/08; C. Wust et Cie. [Locking device] 4,561/09; Allgemeine Elektricitäts-Ges. [Protective devices for A.-C. circuits] 5,717/09.

Traction: Stevens [Control of motors for petrol-electric vehicles, &c.] 17,822/08; Holmes [Trolley-head] 19,482/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Signalling] 21,596/08; Spencer [Controllers] 21,988/08; Saunders [Anchoring conductors] 24,701/08; Cumont, and Compagnie de Signaux Electriques pour Chemins de Fer [Signalling] 5,565/09; Ponder and Shook [Rail-joints] 11,025/09; Parker, Grout, and Scanlan [Operating points from vehicles] 12,218/09.

Miscellaneous: Manders [Production of continuous electrical oscillations] 23,170/08; Light Electric Motor Co., and Higgins [Rotary brushes] 26,283/08; Hill, Barham, and Harrington [Illuminated sign] 5,100/09; Moss [Fire-alarm] 15,718/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: Duschnitz, 11,578/09.

Electric Ignition: Bosch, 18,457/09.

Switchgear, &c.: Petersen [Switch-throwing devices] 12,344/09; Akt.-Ges. Brown, Boveri, et Cie. [Regulators] 16,630/09; Kleber [Lamp fitting] 21,672/09.

Miscellaneous: Electric Boat Co. [Torpedoes] 20,852/09.

Opposition to Grant of Patents

18,044/07. **Single-phase Commutator Motor.** Felten & Guilleaume Lahmeyerwerke Akt.-Ges. A patent has been granted on this application in spite of opposition. It refers to a motor in which the ratio of the E.M.F.s applied to the rotor and stator windings is varied to obtain different speeds, and was abstracted in Electrical Engineering, July 9th, 1908, p. 86.

16,260/08. **Utilisation of Exhaust Steam.** J. Howden & Co., Ltd., and W. H. Owen. Opposition has been entered to the grant of this patent, which claims the admittance of live steam into the low-pressure reservoir by means of an automatic valve when the supply of exhaust steam fails.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

19,402 of October 16th, 1895. **Return Feeder Boosters for Railways, &c.** W. E. Heys (*G. Kapp*). This is the master patent covering the use of storage batteries, or rotary boosters in series with track return feeders for the purpose of keeping the track potential at all return feeding points approximately equal and as near earth potential as possible. Some further information with regard to this patent is given on page 891 of this issue.

19,454 of October 16th, 1895. **Railway Signalling.** W. R. Sykes. An electromagnet mechanism enables two or more signals to be operated by one lever, the position of the points determining which of the signals shall be operated. Means are provided for preventing malicious tampering with the signals.

19,730 of October 21st, 1895. **Boiler Furnaces.** E. and A. W. Bennis. This patent is for mechanically-reciprocated fire-bars, the movements of which in the one direction are simultaneous, while in the reverse direction they take place step by step. The bars are supplied with a jet of steam or air in front.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: Crompton & Co., A. J. Hodgson, and J. W. Ewart [Gravity feed arc lamp] 12,552/01; F. Le Tall (*Cooper-Hewitt Electric Co., U.S.A.*) [Mercury-vapour apparatus] 14,165/03.

Dynamos, Motors, and Transformers: A. H. Midgley and A. P. Wright [Constant-voltage variable-speed generator] 13,741/03; G. Westinghouse [Vertical-shaft turbo-generator] 13,189/04; L. Torda [Commutating poles] 14,250/04.

Incandescent Lamps: W. L. Voelker [Filaments of carbides of uranium, titanium, &c., and arc furnace for producing these] 11,344/00.

Storage Batteries: A. Heinemann and W. Schafer [Wood-charcoal paste electrolyte] 15,047/97; A. Smethurst and T. H. Bishop [Box and cover for ship and car cells] 14,087/04.

Telephony and Telegraphy: R. Weinmar [Recording telephone calls] 12,789/99; F. B. Herzog [Electrolytic annunciators] 13,174/99; R. Richmond and G. E. Clare [Telephone set with call recording device] 12,618/05; I. B. Birnbaum and H. G. White [Central-battery telephone system] 12,690/05.

Miscellaneous: A. B. Webber and Standard Time Co. [Synchronising clocks] 12,518/01; W. Huguet and L. Minart [Electrically-propelled submarine] 14,024/03; J. B. Loison [Centrifugal separators with self-contained motors] 14,105/03.

Digitized by Google

PENDING ELECTRICAL LAWSUITS

AMONG the cases which are to be heard during the Michaelmas sittings is an action brought by the British Thomson-Houston Co., Ltd., against the Midland Railway Co. This will be heard with witnesses before Mr. Justice Warrington. The British Thomson-Houston Co. allege that the Midland Railway Co. have infringed their patents covering the multiple unit control system for electric traction. The equipments in question were supplied by Siemens Bros. Dynamo Works, Ltd., in connection with the conversion to electric traction on the single-phase system of the Heysham-Morecambe section of the Midland Railway Co.'s system.

Another interesting and important action down for hearing before Mr. Justice Warrington is that brought by the Donnersmarckhütte Oberschlesische Eisen- und Kohlenwerke Akt.-Ges., of Zabeze, Germany, against the Electric Construction Co., Ltd., for alleged infringement of the two Ilgner patents for the automatic control of electrical flywheel sets in connection with the driving of reversing rolling-mills. The hearing of this case, however, will probably be deferred until the decision upon an application made by the Electric Construction Co. that the patents in question should be revoked under Section 27 of the Patents Act, 1907, on the ground that the patented articles are manufactured mainly outside the United Kingdom. The hearing of this application has in its turn been delayed by a dispute as regards the method of procedure, and an appeal from the Comptroller's decision on this point will be heard by Mr. Justice Warrington during the coming term. Abstracts of the two patents in question, together with the Comptroller's decision with regard to the submission of evidence, were given in ELECTRICAL ENGINEERING, April 1st, 1909, p. 305.

An important case will come before Mr. Justice Neville. This is a "friendly" action brought by Messrs. J. H. Holmes & Co., of Newcastle, against the Associated Newspapers, Ltd., who have adopted the Kohler push-button system for the control of their electrically-driven rotary presses printing the *Daily Mail*, *Daily Mirror*, &c. The question at issue is whether or not this system is an infringement of the Clatworthy patent printing press control system, of which several examples have been installed by Messrs. J. H. Holmes & Co., the owners of the patent. A complete description of the Kohler system was given in ELECTRICAL ENGINEERING, June 3rd, 1909, p. 506, in connection with the installation at the *Times* printing offices.

Mr. Justice Joyce's judgment with regard to the alleged infringement of the Bremer arc lamp patent by Mr. G. Braulik will probably be delivered before long.

The action brought by Lloyds against the Marconi International Marine Communication Co., Ltd., is down for hearing before Mr. Justice Warrington, but will doubtless be discontinued, as by arrangement with the Government, who are taking over both the Marconi and Lloyds stations in question, the agreement which was in dispute is to be cancelled.

Finally, an action will be brought before Mr. Justice Eve to settle a dispute between the Llandudno Urban District Council and the Llandudno & District Electric Tramways, &c., Co., with regard to the interpretation of a portion of an agreement between the two parties relating to the supply of current for traction purposes by the District Council to the Company.

We refer elsewhere in this issue to the case of the "Z" Electric Lamp Syndicate *v.* Marples, Leach & Co., which was mentioned in the Court of Appeal on Tuesday. This action, however, is not down for hearing during the Michaelmas term. There are rumours that it is not outside the bounds of possibility that there will be a still more important patent action in the near future in connection with metal filament lamps, but in any case this will not be heard in the Law Courts before Christmas.

LOCAL NOTES

ACCRINGTON: *Assessment of Electrical Undertaking.*—In consequence of the assessments of the electricity and tramways undertakings having been very much increased, the Chairman of the Electricity Finance Committee, with the Town Clerk and Borough Treasurer, has been instructed to go fully into the matter with authority to lodge notice of appeal.

BELFAST: *Centre Tramway Posts.*—At last week's meeting of the Tramways and Electrical Committee a deputation asked the committee to reconsider the project for removing the central tramways poles in favour of poles on the side walks on the grounds that the "islands" in the centre of the roadways afforded safe places of refuge to pedestrians, and thus prevented many accidents. The committee promised to give the matter consideration.

BEXHILL: *Electrical Exhibition.*—A Sub-Committee has been formed to consider the question of holding an electrical exhibition.

BLACKPOOL: *Electricity for Illuminations.*—The Electricity Committee have decided to supply electrical energy, free of charge, to consumers for exterior illumination during the aviation meeting.

BRADFORD: *Tramway Accounts.*—The gross receipts of the tramways for the half-year to September 30th amounted to £134,500, an increase of £4,100 over the corresponding half of last year. On the expenditure side there is a saving of £1,800. The net profit for the six months is estimated at £19,900, against £13,900 last year.

BRAY: *Electric Lighting Loan.*—The Local Government Board have sanctioned a loan of £1,000, for new generating plant. An advertisement for this plant, which includes Diesel engines, appeared in our last issue.

BRIERLEY HILL: *Tramways.*—Heads of an agreement in connection with the construction of the Brierley Hill, Quarry Bank, and Cradley Heath tramway have been submitted by the Dudley and Stourbridge Electric Traction Co., Ltd.

BRITISH COLUMBIA: *Electric Railways.*—The preliminary work has been started in connection with the Jordan River water-power generating station of the British Columbia Electric Railway and Lighting Co. It will have a capacity of 10,000 h.p., and it is hoped to have the power-house in operation by November next year.

BUENOS AYRES: *Tube Railways.*—Four petitions have been presented to the municipality applying for concessions for the construction of the Tube Railways, and a report has been presented by the Public Works Committee upon the matter. Apparently, however, this report does not deal with the merits of the three schemes, but lays down general principles upon which any scheme should be sanctioned. The applications are from the Western Railway Co., Messrs. Bracht & Co., the Central Argentine Railway Co., and the Anglo-Argentine Tramways Co. Whilst on the one hand the municipality claim that they have sole right to grant concessions for the use of the subsoil, all the schemes are now before Congress, and will be reported upon by it.

CARDIFF: *Report on Tramway Track.*—Some criticisms of the report by Mr. W. Howard Smith upon the tramway track were made at the meeting of the Corporation last week, it being stated that many of the recommendations had been put into force before the expert was called in. The Borough Engineer and the Electrical Engineer are now to report upon the experts' report.

DAWLISH: *Electricity Supply.*—The Electric Supply Corporation, who hold a provisional order for this district, have submitted plans of their proposed mains. The Council insist on underground mains except in the outer district, where ornamental posts are recommended.

DERBY: *Extension of Area.*—A proposal is to come before the Council relative to extending the limits of the electricity supply area, to include the urban district of Alvaston and Boulton, and the parishes of Littleover, Breadsall, Chaddesden, Normanton, and Sinfin Moor, in the rural district of Shardlow, and Markeaton and Darley Abbey in the rural district of Belper.

DUDLEY: *Electricity Accounts.*—The report and statement of accounts of the municipal electricity undertaking for the past completed year has been issued. Owing to the bad state of trade the units sold have decreased by 44,571 compared with

Digitized by Google

the previous year, the reduction being chiefly on the tramway and motor supply. An increase in the number of units supplied for private lighting has taken place. The year's working has resulted in a gross profit of £5,872, a decrease of £105 compared with the previous year, the net profit being £395. In November last the two-rate system of charging was abandoned and a flat-rate system substituted, and the alteration is now working well. A great deal of trouble has been experienced during the year from breakages of main cables by mining, resulting in several failures of the supply. The total costs were 1·56d. per unit, against 1·43d. in the previous year.

FLEETWOOD: *Purchase of Electric Supply Co.*—The purchase by the Council of the Fleetwood & District Electric Light and Power Co. has now been completed. The total purchase price amounted to £21,253.

GREENOCK: *Electricity Accounts.*—The accounts of the electricity undertaking for the year to June 30th, 1909, show that the total income was £23,709, and that, after meeting all expenditure, the gross profit amounted to £11,290. After meeting interest, sinking fund, and depreciation, there is a net balance of £1,045. Of this amount, £1,000 has been set aside as the nucleus of a reserve fund. The total number of units sold was 3,495,852, an increase of 6·7 per cent. compared with the previous year. The working costs per unit sold have been reduced from 1·04d. to 1·85d.

HESSLE: *Electricity Supply.*—The Council are unwilling to accept the terms of an offer to supply electricity by the Hull Corporation, but a deputation is to meet the latter body.

HULL: *Electricity Discounts.*—A sub-committee is to consider a suggestion by the Council of the Chamber of Trades that lighting consumers of over £20 per annum should be allowed the same discount, for prompt payment, as power users.

INDIA: *Electrically-operated Jute Mill.*—The first electrically-operated jute mill has been opened in Calcutta. The plant was installed by the Lahmeyer Electrical Co., Ltd.

KINGSTOWN (IRELAND): *Tramway Speeds.*—The Council have agreed to certain increases in the speeds of the "special" cars of the Dublin United Tramways Co. within the business portion of the district.

KOREA: *Telegraphs and Telephones.*—According to the American Consul at Seoul, since the taking over of the telegraph and telephone lines in Korea, in July, 1905, the total length of the telegraph lines, then about 1,930 miles, has been increased to approximately 7,000 miles. As for the telephone system, five years ago it existed mostly at Seoul, and the total length of the wires was less than 100 miles. To-day it exists in all the principal cities, its length having increased to over 4,500 miles.

LONDON: *London County Council: Tramways.*—The reconstructed line from Queen's Road along Lavender Hill to Clapham Junction was inspected by Col. Yorke on behalf of the Board of Trade last week. The line is now working.

The following are the terms of the agreement between the City Corporation of the County Council for the running of the tramways over Blackfriars Bridge. The lease is for 21 years, and provides for the payment to the City Corporation of yearly rents of £500 and £1. The rent of £500 is not intended to cover any part of the expenditure upon the widening of the bridge, but is in consideration only of the cost entailed in the construction of the tramway itself. The amount represents approximately the annual capital charges in respect of this. It was arranged in 1906, when the general agreement on the matter was entered into, that the Council should defray the cost, not exceeding £30,000, of providing underground subways for pedestrian traffic at the northern end of Blackfriars Bridge, where the tramways turn round on to the Embankment.

County of London Co.'s Mains.—At the meeting of the Court of Common Council, on October 7th, Mr. Wilkinson inquired what was being done with regard to the notice given by the County of London Electric Supply Co., to lay mains in the eastern portion of the City (see ELECTRICAL ENGINEERING, September 30th, p. 860). The Chairman of the Streets Committee said that the Committee were not prepared to consent to the route suggested by the company. Negotiations were proceeding with the object, if possible, of avoiding any street disturbance.

St. Pancras: Electric Lighting Loan.—A loan of £3,299 for electrical purposes has been taken up with the L.C.C.

Stepney: Electric Lighting Loan.—A loan of £7,000 for electrical purposes has been taken up with the L.C.C.

Woolwich: Tramways.—The tramway route from Rainton Road, Greenwich, *via* Woolwich Road to Chapel Street, Woolwich, is to be reconstructed upon the conduit system, in order to obviate any difficulty with Greenwich Observatory.

Woolwich: Electric Lighting Loan.—A loan of £3,160 for electrical purposes has been taken up with the L.C.C.

MEXICO: *Necaxa Accident.*—Col. Goethals, chief engineer in charge of the Panama Canal works, has just completed an investigation of the Necaxa dam of the Mexico Light & Power Co. After paying a tribute to the organisation and equipment of the company's undertaking generally, Col. Goethals states that the present method of repairing the dam will preclude any possibility of such an accident as happened at Necaxa last winter happening again.

MIDDLESBROUGH: *Electrolysis.*—The Electrical Engineer and the Gas Manager will in future act in co-operation in order to prevent electrolytic action between the electric and gas mains.

Electricity Accounts.—A complete year's working of the arrangement with the Power Company has now been completed, and the results have exceeded anticipations. There is a net profit of £1,277.

Automatic Regulator.—The British Westinghouse Co. have offered to purchase the patent rights for England of an automatic regulator invented by Mr. H. M. Taylor, the Borough Electrical Engineer., and his assistant. Two of these machines have been built and put into service at the Council's electricity works, and it has been decided to allow the inventors £15 each as out-of-pocket expenses in connection with them.

NEWCASTLE (Ireland): *Electricity Supply.*—The Council have decided to inquire the cost of the preparation of a report upon a scheme of electric supply for the district.

NEWPORT (Mon.): *Electricity Undertaking.*—Mr. C. P. Sparks, Chief Engineer of the County of London Electric Supply Co., Ltd., has been appointed, at a fee of 250 guineas, plus travelling and out-of-pocket expenses to report whether the Corporation electrical undertaking is being worked to the best advantage, what, if any, improvements or alterations are desirable, and whether it is desirable to increase the plant as suggested by the Borough Electrical Engineer's report on the question of tariff, method, and system of generation.

OLDHAM: *Rhodes Bank Electricity Works.*—A sub-committee has been appointed to consider the best means of disposing of the plant at the Rhodes Bank electricity works.

OULTON BROAD: *Electric Lighting.*—A sub-committee has been formed to consider the carrying out of the terms of the Council's electric lighting order.

PLYMOUTH: *Electricity Accounts.*—The accounts of the electricity undertaking for the year ending March 31st show a net profit of £2,232, of which £1,991 will be devoted in aid of the rates, as against £1,300 in the preceding year.

PRESTON: *Tramways Undertaking.*—In reporting upon the Council's accounts for the year to March 31st, the elective auditors express the opinion that the Tramways Committee are entitled to the thanks of the burgesses for the successful manner in which they have worked the tramways, and also for the sound manner in which they are dealing with the finances of the undertaking.

RAWTENSTALL: *Tramway Running Powers.*—The Tramway Committee recommend the Council to approve a scheme of through tramcar running between Bacup, Accrington, and Rawtenstall.

REDDITCH: *Electric Omnibuses.*—A report has been presented to the Council with regard to providing a service of electrical omnibuses for the town. The estimated cost is £5,000, but the Works Committee are unable to recommend the Council to undertake such a scheme at present, but propose that every facility should be given to a private company.

ROCHDALE: *Electricity Accounts.*—The accounts for the year to March 31st show a gross profit amounting to £10,608, and after meeting capital charges there is a net profit of £4,830. Compared with the previous year, there is a decrease in the output, but actually this is not the result of metal filament lamps, as the lighting units increased, but is due to a temporary power load in 1907-8. A revision of the supply charges is expected to reduce the revenue for the current year by £700.

ROYTON (Lancs.): *Supply of Electrical Energy.*—An application has been received from the Oldham Corporation for permission to supply in this district. The matter has been adjourned for a month.

RUSSIA: *St. Petersburg Tramways.*—It is stated that a proposal has been made to the St. Petersburg Municipality to employ autocars on the tramway routes for a number of years, instead of converting the lines to electric traction immediately.

SIDMOUTH: *Electric Lighting Order.*—The Board of Trade have revoked the electric lighting provisional order granted to the Council in 1903.

SOUTH AFRICA: *Coast Lighting.*—A commission has been appointed to inquire into the lighting of the coast of Cape Colony.

SOUTH SHIELDS: *Meters on Tramcars.*—The Corporation have decided to install meters on the tramcars, and to pay the cost out of the revenue.

SWINDON: *Electricity and Tramways Undertaking.*—Special reports have been prepared by the Electrical Engineer and Tramways Manager dealing with the administration of their respective undertakings. No drastic alterations in present procedure are recommended. Halfpenny fares are to be abolished, except on workmen's cars. The tramwaymen's annual holiday is also to be reduced from eight to six days.

WESTHOUGHTON: *Charges for Lighting.*—The Lancashire Electric Power Co. have made an offer to supply current for lighting the Council offices, library, and technical school at 4d. per unit less 10 per cent., the minimum charge to be £65 per annum.

WHITBY: *Electricity Profits.*—The profits upon the municipal electricity undertaking last year amounted to £700, the greatest since the works were commenced. The Engineer advises the purchase of electric flat irons, kettles, and food warmers to lend out on hire.

Digitized by Google

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

WALLASEY.—Tenders are invited for paper insulated, lead-covered and armoured cables. Particulars from the Engineer, and tenders by October 19th.

Miscellaneous

ARGENTINE.—The *Review of the River Plate* states that Messrs. Guerrico & Williams have applied to the Buenos Ayres municipality for a concession for electric tramways in Bahia Blanca.

AUSTRALIA.—Tenders are invited by November 23rd by the Postmaster-General at Melbourne for two sets of accumulators. Copy of the conditions, &c., may be seen at the Intelligence Branch of the Board of Trade.

DUNDEE.—Tenders are invited by October 23rd for 45 tons of steel tramway rails. Particulars from the City Engineer.

GREAT WESTERN RAILWAY CO.—Tenders are invited by October 18th for stores, including telegraph apparatus; wires and cables; arc lamps, carbons, &c. Particulars from the Secretary, Paddington Station.

JAPAN.—It is proposed to lay down an electric tramway system in Osaka.

MERTHYR TYDVIL.—The Guardians have decided to change the lighting of the workhouse and infirmary from gas to electricity.

MOUNTAIN ASH.—Tenders are invited by October 25th for the supply of electrical stores.

SOUTH AFRICA.—Tramway extensions of an estimated cost of £56,600 are contemplated by the Johannesburg Corporation. The *Board of Trade Journal* states that tenders will be received by the Chairman of the Tender Board, Cape Town, by October 19th, for the supply of eight electric motors. This information, of course, is only of value to those firms having agents in Cape Colony whom they can instruct by cable.

WALLASEY.—The Council require overhead line material, poles, wire, cars, &c., for about three miles of tramway. Particulars from the Engineer, and tenders by October 19th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

S.E.—Branch Library, New Cross Gate (£4,500). Architects, Castle & Warren, Talbot House, Arundel Street, W.C.

Proposed new R.C. Schools, Pitman Street, Camberwell. Rev. Canon Murnane, for the Trustees.

Alterations and additions to Police Station, Kennington Road (£7,100). Architect, J. Dixon Butler, New Scotland Yard.

Alterations to Metropolitan Water Board's Works, Battersea (£1,160). J. W. Restler, Deputy Chief Engineer, Savoy Court, Strand, W.C.

PROVINCES.

ALTRINCHAM.—Tenders are invited for wiring the County High School for Girls, Bowden Lodge, Cheshire. Particulars from Messrs. Sankey & Cubben, 4 Chapel Walks, Manchester, and tenders to the Clerk to the Education Committee, Market Street, Altrincham, by October 23rd.

BARNSLEY.—Boys' School (£4,000). Council of St. Mary's Church, Barnsley.

BLACKPOOL.—Sunday School and Chapel. Baptist Church Trustees, Hornley Road, Blackpool.

EXETER.—Block of shops and dwelling houses. Architect, E. Ellis, Polsloe Road, Exeter.

FOLKESTONE.—Extensions to public library (£5,000). A. E. Nichols, Surveyor, Folkestone Town Council.

Proposed new buildings (£10,000) for Harvey Grammar School. A. E. Nichols, Surveyor, Folkestone Town Council.

SALISBURY.—Chapel. Architects, Morley & Son, Craven House, Kingsway, W.C.

STOCKPORT.—Isolation block (£1,800). Builder, W. Beattie, Stockport.

SUTTON COLDFIELD.—Post Office. Architect, Henry Williams, Queen Street, Sutton Coldfield.

TORQUAY.—New Town Hall and Municipal Buildings (£30,000). Architect, T. Davison, 28 Great Ormond Street, London, W.C.

Pavilion (£15,000). Surveyor, H. A. Garrett, Torquay Town Council.

WOLVERHAMPTON.—High school for girls (£18,500). J. Hutchings, Stafford, and Fleeming & Son, Wolverhampton, joint architects.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Melbourne Tramway Co. have entered into a contract with the Woods Gilbert Rail Planer Co. for dealing with 60 miles of the company's tram lines. The contract includes removing all unevenness in the rails.

BLACKBURN.—The tender of the Westinghouse Co., for the supply of electric motors for the electricity department, has been accepted.

DUDLEY.—The D.P. Battery Company, Ltd., have received an order to supply, erect, and maintain for a period of ten years, a storage battery of 256 cells of their LS. 37 type. This battery is capable of supplying over 1,000 amperes for an hour.

LONDON: *London County Council.*—The following are among some recent tenders which have been accepted by the County Council:—High-tension cable, Western Electric Co., £4,757. Ten tenders were received, ranging from the one accepted to £7,031. The estimate of the chief officer of tramways was £5,000.

For the supply of low-tension cables, ten tenders were received, the lowest being that of the Union Cable Co., Ltd., at £31,996. As this tender provided for cables of foreign manufacture, and the next tender, that of the British Insulated & Helsby Cables, Ltd., was so close, viz., £31,999, it has been decided to accept the latter. This firm's tender has also been accepted for feeder pillars at £1,116. The number of tenders for these was twenty-four, the highest being £2,047.

The tender of Messrs. Hadfields' Steel Foundry Co., Ltd., has been accepted for the supply of special work for the reconstruction of the Beresford Square—Hill Street tramways at £502.

The tender of the Frodingham Iron & Steel Co., Ltd., has been accepted for the supply of special slot rails for the reconstruction of Highgate Hill tramways at £2,036.

For the roadwork and platelaying in connection with the reconstruction of the Highgate Hill tramways, the tender of Mr. A. N. Cole, of Paddington, has been accepted at £19,101.

The Council are having a special specimen car constructed for use on routes with steep gradients, and in this connection have accepted an offer of the Westinghouse Co. to supply a set of electrical equipment and brakes for £361 10s.

Eleven tenders were received for the provision of choke coils, &c., to be fitted to 25 motor generators in tramway substations, ranging from £2,706 to £1,098. The tender of the Electric Construction Co., Ltd., at the latter amount has been accepted.

PLYMOUTH.—The Council have accepted the tender of the Brush Electrical Engineering Co. for a turbo-generator at £2,244. The Education Committee received the following tenders for the installation of electric light at Regent Street School:—David Sale (accepted), £124; W. G. Heath & Co., £135; Lord & Shand, £136; W. J. Corse & Co., £140.

ROTHERHAM.—The Council have accepted the tender of Reavell & Co., at £405, for a motor compressor. The tenders of Callender's Cable & Construction Co., Ltd., at £2,187, for the annual supply of cables; and the Reason Manufacturing Co., Ltd., for the annual supply of electricity meters, have also been accepted. For engineering stores for the tramways department, the tenders of the following have been accepted:—India Rubber & Gutta Percha Telegraph Works, Ltd.; London Phosphor Copper & Bronze Co.; Vacuum Oil Co.; Griffiths Bros. & Co.; British Westinghouse Co.; Tempered Spring Co., Ltd.; Tramway Supplies, Ltd.; General Electric Co., Ltd.

ROCHDALE.—The tender of the Lorain Steel Co. has been accepted for the supply of rails, fishplates, &c.

STRETFORD.—The Council have accepted the tender of the Vulcan Motor Co. for a 16 h.p. petrol motor arc lamp wagon with hydraulic lift at £385. They have also accepted the tender of J. Hodgkinson, Ltd., for a coal transporter, weighing, feeding, and storage plant for the electricity undertaking, at £682.

COMPANIES' MEETINGS AND REPORTS

BROWN, BOVERI & CIE. A.-G. BADEN, SWITZERLAND.—The report for the year 1908-9 shows that in spite of keen competition and a falling off in orders, the company is able to pay a dividend of 11 per cent., as in the previous year. The net profit amounts to 2,630,421 frs., which, with the amount of 122,389 frs. brought forward from the previous year, gives a total surplus of 2,752,810 frs. The sum of 250,000 frs. is placed to reserve fund, and the remaining 139,790 frs. carried forward. Of the subsidiary companies, the Elektrizitäts Ges. Baden pays 5 per cent.; the Elektricitätswerk Olten-Aarburg 6 per cent.; the Brown, Boveri & Cie. A.-G. Mannheim (whose works were shut down for seven weeks on account of labour troubles) 6 per cent.; the Tecnomasio Italiano Brown Boveri, Milan, 6 per cent.; the Compagnie Electromécanique, Paris-Le Bourget, 10 per cent.; and the "Isolation" A.-G. Mannheim-Neckarau, 6½ per cent. The relations of the parent company with the Allgemeine Elektricitäts-Ges. have been broken off.

DRAKE & GORHAM.—The report for the year to June 30th shows a net profit of £2,282, in addition to the sum of £1,327 brought forward. After paying a dividend of 2½ per cent., the sum of £484 is carried forward. The meeting is on October 20th. The report states that the installation work in the northern district has diminished owing to depression of trade.

ANGLO-AMERICAN ELECTRIC CO.—The accounts for 1908 show a net profit of £6,698, which is carried forward.

ROSARIO ELECTRIC CO.—Including the amount brought forward, the profit for the year ended June 30th last amounts to £41,563. A dividend of 5s. each on the ordinary shares (making 8 per cent. for the year) and 8 per cent. (less amount already paid) on the second preference shares, is recommended, and after adding £15,000 to reserve, the sum of £9,282 is carried forward. The directors have ordered an additional 1,000 kw. generating set.

MISCELLANEOUS CITY NOTES

MEXICAN LIGHT & POWER CO.—A dividend of 1 per cent. has been declared upon the ordinary shares.

STOTHERT & PITT.—A dividend of 6 per cent., free of income tax, is declared upon the ordinary shares, placing £500 to reserve, and carrying £1,587 forward.

INDO-EUROPEAN TELEGRAPH CO.—An interim dividend for the June half-year of 5 per cent. per annum, free of tax, has been declared.

CUBAN TELEPHONE CO.—It is stated that there will shortly be offered for subscription £1,050,000 5 per cent. first mortgage convertible gold bonds of this company.

APPOINTMENTS AND PERSONAL NOTES

The Mountain Ash Urban District Council invite applications by October 25th for an electrician to take charge of their Ynysybwl sub-stations. Salary, £2 per week.

On Wednesday, the 29th ult., a farewell dinner was given at the Midland Hotel, Manchester, in honour of Mr. K. K. von Krogh, who has resigned his position with the British Westinghouse Company, to engage in consulting engineering work in Norway, his native country. Mr. von Krogh had been with the British Westinghouse Co. for about five years, and had control of the transformer, insulating, winding, and motor and punch departments at Trafford Park. Mr. Newcomb Carlton, managing director of the British Westinghouse Co., presided, and about thirty prominent members of the staff were present. Mr. Krogh has joined in partnership Jacob Prebensen Nissen, of Nedre Slotsgade 15, Christiania, who has been identified with several large high-tension power transmission plants in Norway. The firm will be known as Nissen and von Krogh, and in addition to consulting work will also have a fully-equipped laboratory for carrying out electrical testing of all kinds.

Mr. W. H. Hall, electrical engineer to the Morecambe Corporation, has resigned. A successor is to be advertised for.

The Morecambe Corporation have decided to pay Mr. R. Wright 25 guineas for preparing a report on the condition of the Corporation's electrical undertaking, and also to retain him as consulting engineer for two years at a fee of 100 guineas each year, with an addition of 3½ per cent. on any further capital expended on the works.

The Juvisy Riots.—According to the daily papers, serious disturbances took place in connection with the railway facilities for the aviation meeting at Juvisy, which is about ten miles outside Paris. Impatient at the delays, especially on the return journey, the passengers smashed carriage windows, and threw out the cushions from the trains, and a number of people got out on the line. Eventually, it is stated, the current was switched off to prevent accidents from the third rail, with the result that the whole of the traffic was disorganised.

NEW COMPANIES

ELECTROLYTIC APPARATUS SYND., LTD.—Registered on Sept. 28th, with a capital of £5,000, to adopt an agreement with J. T. Niblett for the acquisition of inventions for electrolytic apparatus. Private company. Registered office: 11 Victoria Street, S.W.

HALESOWEN LIGHTING & TRACTION CO.—Registered on September 29th, with a capital of £10,000, to acquire the Provisional Electric Lighting Order granted to G. Balfour in respect of the district of Halesowen. Registered by Pemberton, Cope, Gray & Co., 5 New Court, Lincoln's Inn, W.C.

THEROL FOREIGN PATENTS SYND.—Registered on Sept. 29th, with a capital of £2,500, to acquire a certain patent, to adopt an agreement with G. G. Bell and J. St. V. Platts, and to carry on the business of electricians, mechanical engineers, manufacturers and workers of and dealers in electricity, &c. The subscribers are:—J. E. Spagnoletti, Bowden Green, Pangbourne, Berks, engineer; H. H. Bailey, 20 Addison Road, Chiswick, W., electrical engineer. Private company. Registered office: Goldhawk Works, Goldhawk Road, W.

WESTMINSTER TOOL & ELECTRIC CO.—Registered on Sept. 30th, with a capital of £1,000 in 500 "A" shares of £1 each and 10,000 "B" shares of 1s. each, to carry on the business of electrical engineers, electricians, suppliers of electricity for light, heat, motive power, or otherwise, manufacturers of and dealers in electrical apparatus, &c. Private company. Registered office: Palace Chambers, Bridge Street, Westminster.

TRAMWAYS (CONDUIT) POINT SYNDICATE.—Registered on October 7th, with a capital of £300 in £1 shares, to acquire, deal with, and turn to account inventions for improvements appertaining to tramway and railway construction, particularly relating to the conduit point system. Private company. Registered by Alfred H. Atkins, Ltd., 27-28 Fetter Lane, E.C.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 to £59 10s. per ton (last week, £60 to £60 10s.).

AGENCY.—Messrs. Geary, Adams & Co., Ltd., 25 Central Arcade, Wolverhampton, have been appointed sole agents for Birmingham and district for Messrs. Davey, Paxman & Co., Ltd., Colchester.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The last day for receiving proofs in the bankruptcy of A. Roberts, electrical engineer, 21 North Parade, Bradford, is October 26th. The trustee is J. H. Haley, 29 Tyrrel Street, Bradford.

DISSOLUTION OF PARTNERSHIP.—J. D. M. Morton and J. D. Butler, trading as electrical and mechanical engineers, at Nettleton Road, Mirfield, Yorks, have dissolved partnership.

WIRELESS TELEGRAPH NOTES

With reference to the statement published last week concerning inland wireless telegraph stations in India, Reuter learns that nothing is known regarding the scheme. The Indian Government is erecting a wireless station at Bombay for the use of shipping, and the P. & O. steamer *Mantua*, which is due at Bombay on the 22nd inst., will be the first ship to exchange wireless messages with India. At present only three ships of the P. & O. fleet have been equipped with the Marconi apparatus. They are the *Mantua*, the *Morea*, and the *Malwa*.

According to the *Australian Mining Standard* it is officially stated that in all likelihood the first two wireless stations to be erected on the Australian coast will be at Fremantle and Sydney, those ports being most advantageously situated for communicating with shipping in the Indian and Pacific oceans respectively. No avoidable delay will take place in dealing with the question of wireless installations as soon as the New Works Appropriation Bill, which provides £10,000 for the purpose, becomes law.

The Times Berlin correspondent states that the Zeppelin III. made an ascent on Monday at Friedrichshaven lasting seven hours, and at heights varying between 200 and 700 metres successfully established wireless communication with Munich and Strassburg. The transmitters, which are supplied with current by two small dynamos, were in the after-car.

A circular has been sent to the shareholders of Marconi's Wireless Telegraph Co., setting forth the terms of the agreement with the Post Office, given in our last issue. The directors are of the opinion that the sale is distinctly satisfactory. The circular also refers to the fire which burned down a considerable portion of the Canadian Co.'s Transatlantic station at Glace Bay on the eve of its completion. Fortunately the damage was covered by insurance. Steps were immediately taken to reinstate the station, and Mr. Marconi, who is now at Glace Bay, reports that there is every reason to believe the Transatlantic service will be re-opened early in the New Year.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A report has been issued by a special committee appointed by the Bradford Engineering Society to make a series of tests with regard to the electric driving of textile factories. The Committee really come back to the conclusion that each case must be considered on its merits, but the report gives an extremly valuable summary of the conditions which are the most favourable for each method of driving. Stated briefly, the conclusion arrived at is practically that if the costs are the same, electric driving is always as good as mechanical driving, and in numerous circumstances both better and more economical. (Page 909.)

Mr. Justice Joyce has decided that the Bremer flame arc lamp patent is invalid for want of subject matter, and that consequently Mr. Braulik's lamp is not an infringement of the Bremer lamp. The judge also expressed the opinion that the Bremer patent is anticipated by Graham's American patent. (Page 909.)

The following books are reviewed in this issue:—"Vectors and Vector Diagrams," by W. Cramp and C. F. Smith; "Hydro-Electric Developments and Engineering," by F. Koester, and "Wireless Telephone Construction," by N. Harrison. (Page 910.)

A paper by Mr. H. E. White, recently read in America, describes several methods of automatic motor control by contactors. (Page 911.)

A new variable resistance, consisting of carbon powder cells, has been brought out for regulating incandescent lamps. (Page 912.)

The electrical equipment of the Lanarkshire Steel Works includes provision for electrical machinery of great variety, but the main mills are still steam driven. An interesting feature is the control of an electrically-driven auxiliary hydraulic pumping plant. Current for lighting is obtained from the company's own generating plant, but the power supply is principally taken from the mains of the Clyde Valley Electrical Power Co. (Page 913.)

The latest pattern of oil switch to be standardised by the British Thomson-Houston Co. is described on page 914.

The hearing of the action brought by Messrs. J. H. Holmes & Co. against the Associated Newspapers, Ltd., for alleged infringement of the Clatworthy patent for the electric driving and control of printing presses was commenced on Friday last. The main feature of the

Digitized by Google

patent is the starting up of the press by a small motor which is geared to the main motor through a reduction gearing and a free-wheel clutch. The small motor is overrun by the main motor when it is desired to run the press up to full speed. It is argued by the defendants that machines previous to the Clatworthy patent embodied this principle, and previous patents and descriptions of machines are cited in support of this allegation. (Page 910.)

Some notes on a new British-made tungsten lamp are given on page 916.

The London Chamber of Commerce are to take up the question of compulsory installation of wireless telegraph apparatus on ocean-going vessels. The first ship of the P. & O. Company to be fitted with wireless apparatus is the *Mantua*. The Post Office propose the erection of a wireless station at Wick, N.B. Some particulars are given of the wireless telegraph systems used in the United States Navy. (Page 916.)

A Canadian power supply company is installing an ice-making plant in connection with its electricity supply system, and special efforts are being made by an American company to extend the application of electric driving to ice-making and refrigerating plants as a means of flattening the load curve. One company in Colorado has erected a combined ice-making and electricity-supply station, in which steam-driven refrigerating machines are supplied from the same boiler plant as the electric generating sets. (Page 916.)

A recent Paper by Mr. E. G. Kennard contains a curve comparing the loss in candle-power of metal filaments and gas mantles throughout their useful life. (Page 917.)

In the King's Bench Division on Tuesday the Armorduct Manufacturing Co. obtained judgment against the General Incandescent Co. for the repayment of monies due to them, and alleged to have been paid to the General Incandescent Co. by a former agent of the Armorduct Co. (Page 917.)

The electrical exhibition organised by the Boroughs of Shoreditch, Hackney, and Stepney was opened on Monday by Mr. W. M. Mordey. There is a representative collection of machinery, apparatus, and fittings for lighting and small power installations, and domestic heating and cooking appliances are very prominent. A novelty shown is a hoist with the motor armature inside the winding barrel; the latter forms the field system of the motor, and is geared to the armature through epicyclic gearing. (Page 918.)

Under Electrometallurgy and Electrochemistry are given some notes on the platinising of metals electrolytically, and the preparation of electrolytic iron direct in a malleable condition. Other subjects treated are water-power in Bavaria, and a proposed electric iron ore reduction and steel-making plant in Canada. (Page 918.)

Agreements have been entered into by the London Electric Supply Corporation for handing over the working of the portion of their undertaking in Westminster to the Westminster & St. James' Electric Supply Companies. The agreements have been made under the London Electric Supply Act, 1908, and the London County Council, as the purchasing authority of the London Companies under that Act, have recommended the Board of Trade to make amendments in them. The Council also question whether the agreements really come within the scope of the Act. The South Metropolitan Electric Light & Power Co. and the West Kent Power Co. have entered into an agreement whereby the former supplies in bulk to the latter. (Page 919.)

The Maidstone Electricity Department suggest the promotion of a Bill dealing with electric wiring.—A scheme of electric tramways is proposed for the suburbs of Edinburgh.—Blyth's Wharf power-house of the Stepney Borough Council will be opened on Wednesday next.—Southampton Corporation are to apply for Parliamentary powers for electric wiring, &c.—The tramway receipts at Manchester for the half-year to September 30th, are £4,000 less than in the 1908 half-year.—The Streets Committee of the City Corporation proposed to undertake further experiments in street lighting. (Page 919.)

An application is to be made by the Barnes Corporation for a loan of £7,000.—A loan of £1,266 has been granted to the Surbiton Council; £12,000 to the Stepney Council; £2,000 to the Yarmouth Corporation, and £4,100 to the Shoreditch Council.—New generating plant is to be installed at South Shields. (Page 920.)

The accounts of the Cleveland & Durham Electric Power Co. show a loss of £3,657.—A scheme is being prepared by the Directors of the District Railway Co. for dealing with the arrears of interest on the guaranteed stock and preference shares. (Page 922.)

An apparatus has been developed by Mr. G. Wilkinson to reduce the waste occasioned by the loss of the heat in water produced by condensation in steam-pipe mains. The device takes the place of a steam trap, and returns the condensed steam to the boiler without any considerable drop in its temperature. (Page 923.)

Among the specifications published by the Patent Office on Thursday last was one by F. G. Holmes for a tramcar trolley head provided with arms for preventing the wheel leaving the wire. The Gluhlampenwerk Anker Ges. claim the introduction of a small quantity of phosphoretted hydrogen into the bulbs of metal filament lamps by painting the leading-in wires with a certain mixture, for the purpose of preventing blackening of the bulb. A continuous-current machine, with rotating armature and field, but stationary brushes, has been invented by some Russian engineers. In one form, the rotating field is produced by a three-phase winding. The high relative speed is said to lead to reduced cost and weight for a given output. J. S. Peck has covered an automatic regulator for flywheel load-equalising plant for preventing the return of energy to the supply mains, and the British Thomson-Houston Co. have developed an automatic signalling system which utilises the high impedance offered by steel rails to alternating currents. A patent taken out by O. B. Schallenberger in 1895 for improvements in A.-C. induction motor meters, and another by F. J. and R. Chaplin for dynamo brushes of fine crimped copper wires, expire during the current week. (Page 924.)

ARRANGEMENTS FOR THE WEEK

FRIDAY, OCTOBER 22nd.

Physical Society.

5 p.m. Meeting at the Imperial College of Science, South Kensington. Among the Papers down for reading is the following:—"On Cadmium Amalgams and the Normal Weston Cell," by F. E. Smith.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Opening meeting in the Banqueting Hall of the Midland Hotel, when the Chairman, Mr. S. J. Watson, will deliver his Address.

Electro-Harmonic Society.

8 p.m. Smoking Concert at the Holborn Restaurant (King's Hall).

SATURDAY, OCTOBER 23rd.

Junior Institution of Engineers.

7 p.m. Conversazione at Caxton Hall, Westminster, London.

MONDAY, OCTOBER 25th.

P. & O. Batti Wallahs' Society.

7 p.m. Special meeting at Room 24, Third Floor, Queen Anne's Chambers, Westminster, to consider an alteration to the Articles of Association.

WEDNESDAY, OCTOBER 27th.

Institution of Electrical Engineers: Leeds Section.

7.15 p.m. Meeting at the Leeds University, when the Chairman, Mr. W. M. Rogerson, will deliver his Address. The following Paper will be read:—"Notes on Superheated Steam," by A. B. Mountain.

Digitized by Google

ELECTRICAL DRIVING IN TEXTILE FACTORIES

AS a consequence partly of the interest aroused by the discussion of a recent Paper by Mr. W. B. Woodhouse on the electrical driving of textile machinery, a special committee, under the chairmanship of Professor C. F. Charnock, was appointed by the Bradford Engineering Society to carry out experiments and inquire fully into the points in connection with the subject which were in dispute. The expenses of the inquiry were defrayed by private subscription, and the committee was constituted as follows:—

Prof. G. F. Charnock (Bradford Technical College), Chairman, Messrs. H. W. Morley (Cole, Marchent & Morley, Ltd.), F. L. Croft (Croft & Perkins, Ltd.), H. A. Jones, and Dr. Pohl (Phœnix Dynamo Manufacturing Co., Ltd.), F. Wigglesworth (F. Wigglesworth & Co., Ltd.), F. W. Whittaker (Bradford Dyers' Association), H. Bean and W. Eastwood (Newton, Bean & Mitchell), W. B. Woodhouse (Yorkshire Electric Power Co., Ltd.), T. Roles (City Electrical Engineer, Bradford), C. W. Salt and H. S. Ellis (City Electrical Engineer's Department, Bradford), H. W. Barker (Thos. Barker & Son, Civil Engineers), W. P. Steinthal (Steinthal & Boydell), W. Lee (J. Ambler & Sons), and A. F. Barker (Textile Department, Bradford Technical College).

Trials were carried out at Dock Ing Mills, Batley, as an example of spur and bevel, belt and rope driving, and it was found that even in such circumstances the amount of cyclical variation was not so great as had been expected. Tests were also made at the Leigh Mills Co.'s Upper Mills, Staningley, which is partly driven by induction motors from the Yorkshire Electric Power Co.'s system. The Committee also visited the Thor Mill, Whitworth, near Rochdale, on the invitation of Messrs. Siemens Bros. Dynamo Works, Ltd., who supplied the equipment for electric driving. As, however, the large motors installed on each floor could only be said to replace the ordinary rope drive, this mill could hardly be said to constitute a typical example of electric driving. The point submitted was that even with this arrangement the increase in steadiness of turning was such as to lead to increased output, and of better quality, commanding a higher price on the market. Of this no actual evidence could be supplied, and the Committee have been unable to obtain any proof whatever, based on actual experience.

The Committee, after very carefully considering the above results, and after a thorough discussion of all the information before them, arrived at the following conclusions:—

1. That in good installations there is practically no difference in cyclical variation between mechanical and electrical transmission when measured at the end nearest the main drive.

2. That any initial cyclical variation which may exist at the driving end of the above shaft is liable to be increased if transmitted through long shafts. This can, however, in many cases be controlled by known methods of destroying synchronous vibrations.

3. That so far as any irregularity is concerned (excluding breakdowns), electrical transmission will maintain its condition better than mechanical transmission.

4. That in modern textile, combing, spinning, and weaving factories, where those factories are of ordinary dimensions, and where the power is generated on site, power is conveyed with less loss by mechanical than by electrical transmission; but where the plan of the buildings is irregular, involving awkward angles of drives or irregular arrangement of machinery, the saving in power by electrical transmission begins to appear. The Committee find it difficult to arrive at a definite decision as to the exact point where the friction due to mechanical transmission is excessive, owing to the very varied conditions which obtain, but make the following suggestions:—

5. That the friction loss with mechanical transmission is excessive if over 30 per cent. By "friction loss" is meant the proportion which the collective friction of the engine drives and shafting with the belts on the loose pulleys of the driven machines, bear to the total horse-power when the whole load is on the engine.

6. That electrical transmission is likely to be most efficient (*a*) where there are long lengths of shaft from which power is not taken off at intermediate points; (*b*) where machinery is distributed and requires starting and stopping frequently during the day; (*c*) where machines require to run at various speeds and have those speeds altered during motion; (*d*) where there are excessive lengths of shafting, making it desirable to separate these into two or more lengths.

The question as to the adoption of electrical or mechanical driving is largely one of cost, which can only be decided by careful investigation of each individual case. By adopting electric driving, the following advantages can be obtained, whether the power be generated on site or taken from an outside source of supply:—(1) Ease of checking daily the power required for running individual machines and departments, and of detecting any faults or deterioration of the plant. In the case of mechanical driving, this may be done by employing some form of power meter. (2) Ability to run only a portion of the plant—as, for instance, on overtime—without serious loss in transmission. With mechanical transmission, the same object may be attained by the judicious application of clutches, or similar mechanical devices. (3) Reduction in the number of belts, shafts, gears, &c., with consequent improvement in lighting and cleanliness when individual driving is adopted. (4) Ease of regulating the speed, and of introducing periodical speed variations in certain machinery, if individual driving be adopted. (5) Ease of utilising the available space to the best advantage, and of extending into adjacent buildings at any time, irrespective of the lay-out of the same. (6) Saving in the cost of the engine-house and its foundations, the latter made possible by the adoption of a high-speed generating set. Care must be taken that the possible extra cost of other portions of the plant or buildings, or reservoirs, does not more than balance any saving in the direction indicated.

The following further advantages may be obtained if an outside source of supply is available:—(1) A reduction in the first cost of the installation and buildings due to the absence of power generating plant. This, in conjunction with the corresponding saving in floor space, may be utilised for the installation of productive machinery. (2) Freedom to run only parts of the plant, and to work overtime without any increase in the cost per b.h.p. of the power used. (3) Unlimited supply of power available. (4) Less liability of total stoppage, due to the standing plant of the supply authority, as compared with private generating plant.

THE BREMER FLAME ARC LAMP PATENT

The Patent Declared Invalid

MR JUSTICE JOYCE delivered his judgment on Tuesday in the action taken by the British Westinghouse Electric and Manufacturing Co., Ltd., against Mr. G. Braulik for alleged infringement of their Bremer arc lamp patent, No. 18,786 of 1902. The arguments and evidence in the action were fully reported in our issues for June 24th, p. 571, and July 1st, p. 617. The judge's decision is that the patent is invalid for want of subject-matter, and that consequently there is no infringement.

The patent relates to the feeding of the carbons in arc lamps of the converging carbon pattern. The patent—which was amended in December, 1907, when one of the claims was struck out and a disclaiming note added—describes mechanism for the purpose of obtaining a lateral movement of one or both carbons in addition to the downward feeding motion. Two alternative mechanisms are described in the specification. The first consists of an arm which bears against one carbon. An armature attached to the upper end is attracted by an electro-magnet connected in shunt across the arc, and this end also holds the detent, which engages with a star-wheel geared to the feeding-cord drum. If the arc lengthens, the armature is attracted to the magnet, and the swinging carbon pushed towards the other carbon, and this action is continued until the armature has moved to such a point that the star-wheel is released. Feeding then takes place. In the second mechanism, the swinging carbon is moved by means of a loose collar near its burning end, this movement being controlled by a vertical shaft which is given a rotary motion by means of the differential action of shunt and series coils.

The single claim attached to this specification is as follows:—An arc lamp having downwardly pointing electrodes and provided with both downward and horizontal feed mechanism, so arranged that a certain amount of operation of the horizontal feed mechanism takes place before the downward feed mechanism is permitted to operate, subject to the disclaiming note.

The disclaiming note reads as follows:—The lamps to which my invention applies are of the type in which the current is supplied to the electrodes through electrode-holders, in which the upper ends of the electrodes are firmly clipped, and which are capable of being lowered simultaneously through the same distance, and about one of which the corresponding electrode can swing under the action of a device acting near its lower end, and I limit my claim to lamps of this description.

Mr. Braulik first endeavoured to obtain revocation of the

Digitized by Google

patent under Section 27 of the new Patents Act, on the ground that it was inadequately worked in this country. The Comptroller issued an order revoking the patent on this ground, but it was reversed by Mr. Justice Parker on appeal. The action for the infringement then proceeded.

Mr. Braulik not only denied the alleged infringement, but in his defence disputed the validity of the patent on various grounds. He claimed that the invention was contained in several previous patents, and quoted thirteen specifications in support of this—six British, one French, five American, and one German.

The case occupied the Court for eight days last June, when expert evidence was given by Mr. Dugald Clerk, Mr. James Swinburne, and Mr. H. E. Moul on behalf of the plaintiffs, and Profs. S. P. Thompson and J. D. Cormack for the defendants.

His Lordship, having briefly outlined the patent given above, said that apparently the original claim was too wide, and by the disclaiming note the plaintiffs restricted the application of the invention to a particular kind of arc lamp having certain specified characteristics. They did not claim any specified or particular apparatus or mechanism for the purpose indicated, nor was it for any particular device to produce the effect claimed, but was generally for any device which would effect the object claimed in any arc lamp having certain specified characteristics.

It was admitted by the plaintiffs, and could not be denied, that there were considerable errors and inaccuracies in the specification. By letterpress and drawings, it purported to show a mechanism whereby such an arrangement as claimed could be effected in an arc lamp of the type to which the invention referred. The judge then explained that he did not intend to describe in detail the various arc lamps, for he did not profess to understand them. It was not the function of the Court to qualify itself as an expert, and he quoted a precedent for taking this point of view. It was claimed that the Braulik lamp was an infringement, but he thought the real and serious allegation in the case was the validity or otherwise of the Bremer patent. The patent had been challenged on two grounds —(1) that it was invalid for want of subject-matter; (2) that it was anticipated in Graham's American specification (No. 268,218 of 1882). To his mind, the result of the evidence was this. There being already a well-known contrivance or arrangement common, but not universal, in the kind of arc lamp in ordinary use, the plaintiffs' patent was taken out for the application of such a contrivance or arrangement, *mutatis mutandis*, to a precisely similar, if not for the very same, purpose in a specified type of lamp, viz., that described in the claim as limited by the disclaiming note. This contrivance or arrangement was employed in the ordinary arc lamps in common use, as was stated in the evidence, and to employ it in the manufacture of other arc lamps, he thought, was a perfectly natural and the obvious thing to do, and there did not appear to have been the slightest difficulty in doing so. Rightly or wrongly, therefore, he thought that the objection founded on want of subject-matter was, in the circumstances, a good and valid objection, and that, in what was claimed, there was no invention to support. On this ground the action failed. The invention described in Graham's American specification was within the claims of the patent in question, and the lamp there described would work in the manner claimed by the patentee. On the whole, therefore, he thought the plaintiffs' patent was invalid, but the ground upon which he decided was that in the so-called invention of the patentee (Bremer), as claimed, there was no real invention or subject-matter.

He therefore dismissed the action with costs.

The British Westinghouse Co. have given notice of appeal.

REVIEWS OF BOOKS

Vectors and Vector Diagrams, applied to the Alternating Current Circuit. By W. Cramp and C. F. Smith. 252 pp. 8¾ in. by 5½ in. 144 illustrations. (London : Longmans, Green & Co.) 7s. 6d. net.

This is an excellent treatise on vector diagrams and vector algebra, and their application to the solving of the more complex problems of alternating current work, and it presents the subject to the reader in a more lucid manner than is customary in advanced text-books of this class. The authors have adopted the Steinmetz system of calculation, but have altered the notation so as to introduce the decided improvement of distinguishing between the unit vectors and the operator called j. The letter j is employed only as an operator, and one or two dashes are placed after the symbols denoting the magnitude of the vectors, to distinguish the components. Although a few examples are given, illustrating the use of vector algebra in the solution of simple problems connected with choking coils, &c., the reader is assumed to have a thorough grasp of the fundamental laws of the alternating circuit, such as an electrical engineering student in his third college year might be expected to possess. Each chapter covers a particular subject, and though this arrangement makes some of them very long, it has the advantage of enabling anyone who has once grasped the notation to make use of any special chapter without reading through the preceding ones. The first three chapters, occupying rather more than one quarter of the book, deal with vectors and vector algebra in general. The next treats in a useful manner with self and mutual induction and the various coefficients, and leads on to a short chapter on the transformer. The transformer deserves a more complete treatment than is accorded to it, and the same applies in some degree to the induction motor, dealt with in the following chapter. In the latter case, however, complete scale circle diagrams (both the ordinary Heyland and the more complete diagram) for a motor are given in a later chapter on the application of locus diagrams, and the errors introduced in the Heyland solution are pointed out. In a chapter on alternating current commutator motors, the main characteristics of the different types are outlined, equations expressing the values of the various E.M.F.'s are deduced, and some simple examples are worked through. The book concludes with a full treatment of locus diagrams and their applications; in this part, in particular, a more frequent use of worked examples with the results plotted as curves would be an improvement.

Hydro-Electric Developments and Engineering. By Frank Koester. 454 pp. 7¼ in. by 10½ in. 500 illustrations. (London : Archibald Constable & Co., Ltd.) 21s.

The young engineer who means to stay at home should not waste his time with this book, but if he has any inclination to go to the Colonies or to some foreign country it will strongly tempt him to take up a branch of electrical engineering that offers many attractions. Even in a large volume of 452 pages and with excellent illustrations averaging more than one to a page it is impossible to provide a complete treatise on the subject, but compensation is made for its brevity by strict sectioning of the contents and by a bibliography at the end of almost every chapter.

American technical expressions are used, and the definition does not always accompany the first appearance of the word, but the reader need only go on and the meaning will appear later. Eleven pages well illustrated are devoted to the automatic regulation and governing of turbines, but the subject of the hunting of governors is passed over, possibly because no other writer has undertaken to discuss it with any completeness.

Although we have so little opportunity of using water power in this country, it might have been expected that the excellent descriptions of transmission lines in this book would be useful to stay-at-home engineers. But this does not seem likely. The creosoted wooden pole almost always used here is practically unknown in America and on the Continent. The huge steel towers, some of them of extraordinary design, would be useless with us; they would effect no saving in first cost, and would be far more expensive in upkeep.

Wireless Telephone Construction. By Newton Harrison. 74 pp. 7¼ in. by 5 in. 43 illustrations. (London : E. and F. N. Spon.) 1s. 6d.

This little book, which is of American origin, is addressed to the two mysterious classes of person known as the "amateur" and "the every day man," the former of whom wishes to construct a wireless telephone, although he does not understand the principles involved, while the latter desires some insight into the principles, but does not intend to attempt construction. The suggestions as to the construction of a simple equipment with water-cooled copper-carbon arc wave generator contain some practical hints, but leave a good deal for the amateur to decide for himself. There will probably be many little refinements which he will have to devise before he can hope for success. Some of the illustrations are distinctly unnecessary, and the space given to details of battery construction would have been better devoted to quantitative information as to the less familiar parts of the apparatus. The attempts at clearness in the introductory matter are not always happy, as the author is apt to go to extremes both in the directions of vagueness and redundancy. It is perhaps a pity that he has not realised that such delicate work as experimental wireless telephony is not likely to be undertaken with success by one having no practical acquaintance with electric waves, and that the wireless telephone is not a suitable subject with which to commence the non-electrical man's initiation. Nevertheless, if the work succeeds in inducing an amateur to pursue the subject further it will not have been written in vain.

AUTOMATIC MOTOR CONTROL

AMONG the Papers read at the summer meeting of the American Institute of Electrical Engineers was one by Mr. H. E. White dealing with the use of electrically actuated switches controlled by automatic or semi-automatic means for motor control.

With reference to the design of the contactor itself, there is a tendency in recent designs to secure the necessary carrying capacity by forcing the contacts together at considerable pressure, but the gain is greatest for the first increase in pressure, so that it does not pay to attempt to carry the pressure too high. High contact pressure results in the advantage that, when the recoil of the springs takes place at the time the contactor is de-energised, a quicker opening results. The magnetic blow-out has been found equally effective for both direct and alternating current. In contactors for alternating current, laminated magnets are necessary to avoid excessive heating. The action of solenoids on alternating current is quite different from their action on direct current. On alternating current, the tendency is towards constant pull, independently of the position of the armature, with a reduction in magnetising current as the solenoid closes. On direct current, the pull greatly increases as the solenoid operates. The alternating-current contactor closes almost violently, while the direct-current contactor closes more leisurely. The tendency of the alternating-current contactor to hum can be reduced to an unobjectionable amount by the use of "pole-shading" devices.

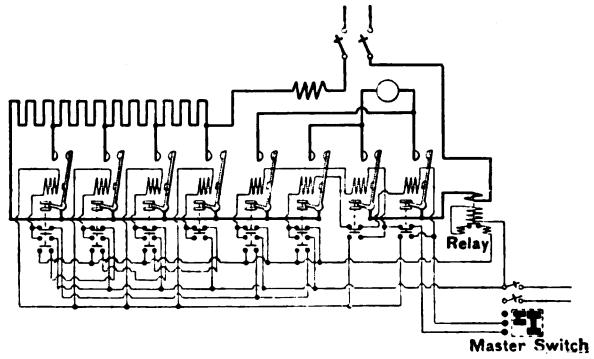

FIG. 1.—CURRENT-LIMIT CONTROL WITH SINGLE RELAY.

In applying contactors to the control of motors a so-called *current-limit* control is usually employed. In the simpler systems, the contactors are so arranged that as each one closes it completes the actuating circuit for the next contactor, thereby causing the controlling resistance to be short-circuited step by step. One or more overload relays are so arranged that this progressive action will be interrupted without causing any contactors to be opened whenever the current exceeds a predetermined amount. In other cases, the contactors are arranged with their operating coils in multiple with the armature of the motor, so that as the motor starts, the increasing electromotive force across the armature will cause the contactors to operate one by one. This arrangement is known as the *counter-electromotive-force* system. The last-named system is open to the objection that if the voltage of the supply system is not constant, the operation of the control is interfered with, the result being that if the voltage is low, the contactors may not close at all, while if the voltage is too high they will close too soon. This is avoided in a modification using potential relays in multiple with the starting resistance, so that as the current in the resistance decreases step by step, the relays will fall out. In some cases, *time-limit control* is useful; that is, the contactors are arranged so that they will be energised in a given time regardless of other conditions. In this case an escapement or dash-pot is usually employed.

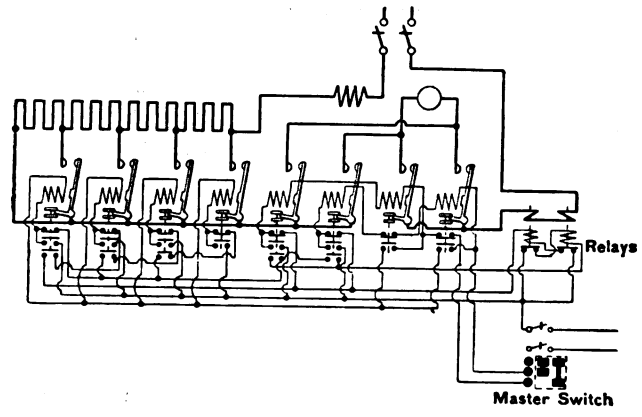

FIG. 2.—CURRENT-LIMIT CONTROL WITH DOUBLE RELAY.

Still another type of control, which may be called *pilot-motor control*, uses some form of an electric motor to actuate a master switch. This motor can be controlled in any manner desired by overload relays or push-buttons. This system is often used where the control is of a comparatively complicated nature, such as in printing-press work. Aside from the current-limit control obtained by the pilot-motor system, two comparatively distinct systems of current-limit control are now in common use. In one of these is used a single relay, with series and shunt coils. In this system, as each contactor closes it completes a momentary actuating circuit for the next contactor, which then closes and establishes a holding circuit for itself independent of the momentary circuit above mentioned. The momentary actuating circuit passes through the contacts and shunt coil of the relay, and causes the iron core of the relay to lift an iron core into the field of influence of the series coil, thereby interrupting the circuit at the relay just after the contactor has completed its holding circuit. When the contactor is fully closed, the interlocks establish a circuit to the next contactor through the relay, so that the above operation will be repeated for this contactor in the same manner, provided the current in the series coil of the relay does not delay the completion of the circuit by holding the iron core up. This system for reversible rheostatic control is shown in Fig. 1. The objection to this system is principally in the complicated interlocks. It has the advantage that the current-limit value for all the contactors can be obtained by adjusting one relay. This system is consequently most commonly used in railway service. A modification using two relays, and shown in Fig. 2, is an improvement in

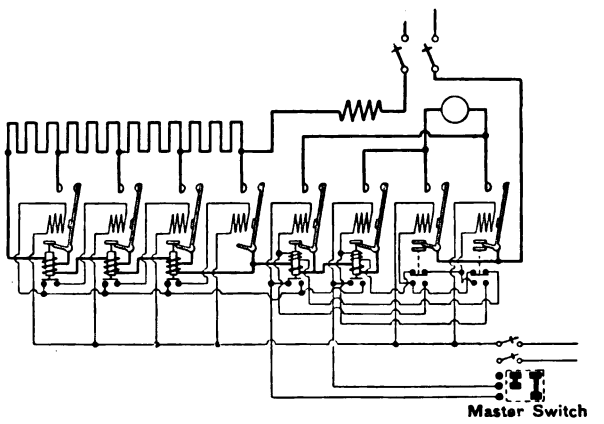

FIG. 3.—REVERSIBLE-CONTROL EQUIPMENT WITH SEPARATE RELAYS.

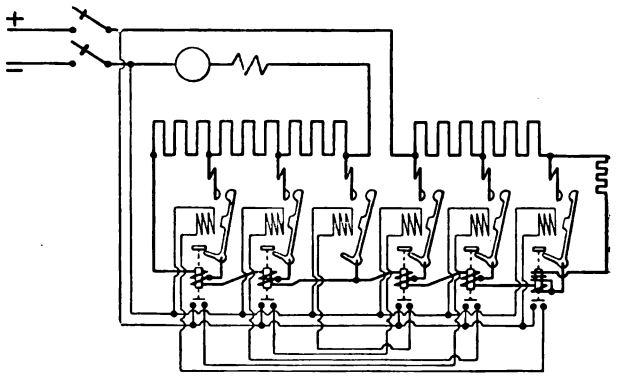

FIG. 4.—CURRENT-LIMIT CONTROL WITH SEPARATE RELAYS ARRANGED TO INTRODUCE RESISTANCE INTO CIRCUIT IN CASE OF OVERLOAD.

Digitized by Google

that less difficulty is met in adjusting the speed of the relays. The second system makes use of a separate relay for each contactor. In its simplest form, each of the accelerating contactors includes as an integral part of itself an overload relay, which is held in the open position by a mechanical connection with the contactor until the contactor is closed, and is then allowed to drop and complete the circuit for the next contactor, only under the control of the current which passes through the contactor and the series coil of the relay. This arrangement is shown in Fig. 3, as used for a reversible-control equipment. A comparison of this system with the preceding ones will show its greater electrical simplicity. By using

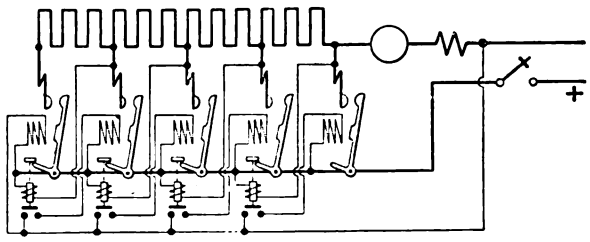

Fig. 5.—Automatic Motor Starter with Separate Shunt-wound Relays in Multiple with Starting Resistance.

separate relays, acceleration can be secured at an increasing rate step by step, or, if desired, at a decreasing rate. As ordinarily arranged, each relay is cut out of circuit as soon as the next contactor closes. In case, however, the circuits are so arranged that the relay is not cut out of circuit until the second next contactor closes, an equipment is obtained which has the interesting property of cutting resistance back into circuit step by step in case of an overload. The connections for accomplishing this result are shown in Fig. 4. Fig. 5 shows a motor starter with shunt type of relays in multiple with the starting resistance as described in the first part of this Paper.

REGULATORS FOR INCANDESCENT LAMPS

A USEFUL pattern of regulator for adjusting the brilliancy of incandescent lamps, developed by Mr. H. S. Martin, can be obtained from the Electrical Regulators & Economisers, Ltd. (51 North John Street, Liverpool). The device consists of a number of carbon powder resistance cells, with means for varying the mechanical pressure on them, placed in series and parallel according to the range and capacity required. Each cell contains

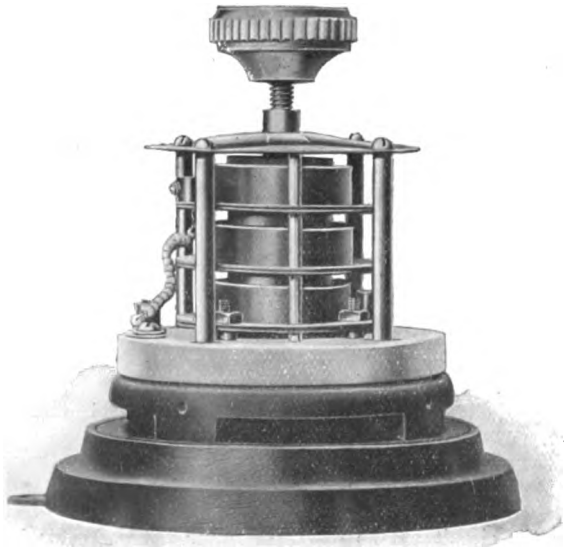

Fig. 1.—Carbon Powder Resistance Regulator for Incandescent Lamps.

a mixture of graphite powder, mica scales, and sand; the function of the mica scales being to give the mixture the necessary elasticity to recover its original volume and resistance when the pressure is removed. Fig. 1 shows a three-cell pattern with the cover removed, and Fig. 2 is an illustration of a larger size showing how the unit cells can be built up to suit any desired conditions. The small regulators can be used to control single lamps in bedrooms, &c., and the large sizes can be used for dimming theatre lamps. The size illustrated in Fig. 1 is about 4 in. by 3½ in., and can be used in series with one 16 c.p. carbon lamp, two 25 c.p. metal filament lamps, or one 50 c.p. metal filament lamp, or a 12 in. propeller fan, with any pressure below 250 volts. The device is supplied with an adaptor comprising a cap and socket with a twin flexible connected to the regulator. This is inserted in the lamp-holder, and the lamp placed in the socket of the adaptor, so that no alteration to the wiring is required. If desired, a cut-off can be provided, combined with

Fig. 2.—View of Large Regulator, showing Method of Assembling Unit Cells.

the regulator, so that the lamp can be switched off entirely when desired. Incidentally it may be mentioned that "overshooting," which has a shortening effect on the life of metal filament lamps, is avoided if the lamps are switched on with one of these regulators in series. We have tested one of the smaller patterns, and have found it to respond immediately to the slightest turn of the knob in either direction. It is also remarkably free from the fluctuations in resistance, due to jarring or vibration, found with the old forms of carbon resistances.

National Institution of Apprenticeship.—In connection with the letter from the Lord Mayor, Sir G. Wyatt Truscott, in our issue of October 7th, calling attention to the work of this Institution, the honorary secretary, Mr. J. S. Ballin, writes us stating that it is unfortunate that so few apprentices have been bound to the electrical and engineering trades. This, he writes, is not due to the unwillingness of lads to be apprenticed, but to the fact that so few good masters are willing to take apprentices on terms that are acceptable by the great majority of lads applying to the Institution for apprenticeship. Mr. Ballin further invites firms who have vacancies for apprentices to communicate with him on the subject.

Standard Specifications for Keys and Keyways.—The Engineering Standards Committee have issued a standard specification (No. 46) for keys and keyways. The report is divided into two sections, the first being a specification for the steel bars from which the keys are to be cut, and the second dealing with the proportions of keys and keyways recommended. The specification requires a minimum tensile breaking strength of 36 tons per square inch, with an elongation of 12 per cent. on the test piece specified. A list of standard sizes is given, and the margins of manufacture to be allowed on merchant bar are defined. The price of the specification is 2s. 8d., post free, and it may be procured from any bookseller or direct from the offices of the Committee, 28 Victoria Street, Westminster. It is published for the Committee by Messrs. Crosby, Lockwood & Son, 7 Stationers' Hall Court, Ludgate Hill, E.C., and 121A Victoria Street, S.W.

Electrical Recording Machines for the American Census.—In connection with the United States census of 1910, a number of electrical recording and tabulating machines will be used. The census will be taken on the card-index system, and some ninety million cards will be dealt with by the machines, which will punch holes in certain squares on each card to record the age, sex, nationality, &c., of the corresponding individual. An operator depresses certain keys of a keyboard, and when all the items are disposed of, a button is pressed, and a group of holes corresponding to the keys depressed is punched in the card. The cards are afterwards passed through tabulating machines, which count the numbers of cards which have holes punched in each separate position. This is effected automatically by bringing a set of needles down on to each card in turn. Where there are holes, the needles pass through the card and touch contacts on the other side. This closes circuits which include electromagnetic counting devices. Each machine is driven by a ½-h.p. electric motor, and it is stated that a very large number will be used.

ELECTRIC POWER AT THE LANARKSHIRE STEEL WORKS

ONE of the most progressive steel works in the West of Scotland is that of the Lanarkshire Steel Co., Ltd. (Motherwell). This firm, whose plant is perhaps the most modern of the large works, manufacture all sizes and types of rolled steel sections. The mills at present have an output of 15,000 tons per month, and range in size from a small 9 in. three-high mill to the large 36 in. bar mill, which turns out ship and beam sections, up to 24 in. by 7½ in., and weighing 100 lbs. per sq. ft.

The firm at quite an early period in the progress of electrical engineering recognised that in this form of motive power lay the opportunity of the future, and it proceeded as an initial installation, to put down two 75-kilowatt 250-volt shunt-wound generators, direct coupled to vertical enclosed engines running at 350 r.p.m. Two similar, but larger, sets each of 175 kilowatt capacity, were also installed. These plants were supplied with steam from boilers which were installed in order to provide steam for gas producers, and current was generated by this means at a fraction of 1d. per unit, inasmuch as owing to day and night running of the plant the boilers were operated at a state of high efficiency.

The works switchboard, which was part of the original contract installed by Messrs. Ernest Scott & Mountain, Ltd., is still in use, in conjunction with another system of supply to be described immediately, and consists of a panel for each of the generator sets, carrying a double pole knife-switch, an ammeter and voltmeter, a magnetic blow-out circuit-breaker and fuses. The board also contains provision for the main distribution circuits, running respectively to the producer plant, the old mill, the workshops, the machines on the bank of the 36 in. mill and the 27 in. mill respectively, the cogging mill, the overhead cranes, which are eight in number, and the works lighting. Each of these circuits is controlled by a double pole switch and suitable fuses, and is provided with an ammeter. A recent addition to this board is the provision of the panel for a motor-generator set, which converts a 400-volt supply from the mains of the Clyde Valley Electrical Power Company to the pressure of the works circuits. The circuit-breaker on this panel is provided with reverse current release to prevent any injury to the motor generator, should it shut down while in parallel with the steam sets.

The bus-bar arrangements of this board are somewhat complex, owing to the fact that special arrangements had to be made with regard to the pumping installation. The board is provided with a set of main bus-bars and also pump bus-bars in order to give 500 volts pressure when operating two pumps situated in a house close to the Clyde in series when both pumps have to be in operation, and also to give 250 volts when one pump only is to be operated. A lighting switch is provided of the three-way two-pole type, capable of placing the lighting circuit either on the main bus-bars or on either set of the pump bus-bars. To deal with the Clyde Valley pumps, which are situated some one and a half miles away from the works, and force water through a 12 in. pipe line against a 260 ft. head, a special board is provided, fitted with a change-over switch capable of placing either one of the two smaller steam generating sets on to either of the pump circuits, or both pumps on to supply at 500 volts. Adjoining this main switch, and geared to it by a special locking gear, are two double-pole, double-break main switches, which control either of the steam sets, and the lock motion is so arranged that it is impossible to place either machine on either pump circuit while the other machine is on the remaining pump circuit, except in the case when two machines have to be placed in series on the two pumps, and in this case the machines are placed in series with their proper polarity. Leading to the pumping station are three main cables, each of 61/10s. section, together with two telephone cables, of the lead-covered, steel-armoured bitumen type, laid directly in the ground with protective boards on the top. At the pumping station there is a duplicate board to the one described above, which controls supply to two 72 h.p. motors, each driving a three-throw pump, delivering 600 gallons per minute against the required head, the water being pumped to a reservoir tank on the works.

The plant, which was installed some two years ago in order to connect the works equipment with the system of the Clyde Valley Electric Power Co., Ltd., consists of a 365 h.p. three-phase Westinghouse squirrel-cage motor, running on the 420-volt 25-cycle supply at about 480 r.p.m., coupled to a 250-kilowatt, 250-volt, shunt-wound generator. This set is started by an oil-enclosed auto-starter. The average number of units per week dealt with by this plant is in the nature of 16,000. The company's own plant is used for lighting only at the rate of 300 amperes throughout the night. The total power required during the day is taken by the motor-generator, which is capable of 50 per cent. overload for one hour in order to deal with peaks in the load, due mainly to the cranes.

From the power station the supply is conducted throughout the works by bare cable, carried overhead on lattice poles of the Lanarkshire Steel Company's own construction, the main poles outside the power house being arranged to carry nine circuits, each of 37/12s. stranded copper. One of these circuits is carried to the auxiliary hydraulic pump house, where an electrically-driven auxiliary pumping plant provides water pressure at week-ends when the main steam plant is shut down. This consists of a compound-wound motor running at 500 r.p.m., developing from 85 to 100 h.p., which drives, by means of a single reduction gear with rawhide pinion, a three-throw ram pump with rams of 3 in. diameter and 9 in. stroke. This set has run for three years from Saturday 2 o'clock until Monday morning at starting up time, at intervals of 7½ to 8 minutes, and during the whole of that time has required no repairs. The running of the pump is controlled automatically by means of a switchboard, specially designed by Mr. Boland, the electrical engineer to the Lanarkshire Steel Co. The no-load circuit-breaker on this board is provided with a mechanical lock, so that no one can start up the pump set until the starting switch is returned to the off position. This lock is effected by means of a solenoid switch in series with the starting switch, so that when the latter is on the first two contacts a shunt circuit is made and the solenoid switch lifts. The hydraulic control of the starting switch is obtained by means of a single valve from the accumulator operating on one side of a ram combination starting switch handle. One ram, which is ¾ in. diameter, is subjected to a constant pressure from the accumulator, while the second ram, which acts in opposition to the first, and which, being 1½ in. in diameter, is capable of overcoming the first ram, is subjected to intermittent pressure dependent on the position of the accumulator. By means of brass washers, which can be placed in the inlets to each ram, and which have small holes pierced in them, the flow of water into the ram chambers on either side can be regulated, and therefore the time taken to put the starting switch in can be controlled; under normal conditions this is adjusted in about 11 seconds. This ram combination operates on an extension of the starting lever handle, suitably insulated, and resistance is thereby cut out of the motor armature circuit.

A motor of 11½ h.p. is used in the testing department to drive a collection of machinery, including a high-speed lathe and a "devil," whose purpose is a rapid trimming down to standard dimensions of test pieces. In connection with the production of gas for the heating of the steel furnaces, considerable use is made of electric driving for the coal conveying plant. Other miscellaneous applications of electric power include an interesting series of electrically-operated cranes in connection with the casting pit and soaking pits in the steel plant. Two of these in the casting pit are of 20 tons lifting capacity, while over the soaking pits are two 15-ton cranes, each of 27 ft. span, and carrying motors of 40 b.h.p. for the hoist, 45 b.h.p. for the travel, and 7 b.h.p. for the cross-travel. The soaking pits are for the purpose of subjecting the ingots obtained from the casting pit to a steady heat, obtained from the combustion of producer gas, for the period of two to three hours, in order to anneal them and re-heat them before being taken to the cogging mill.

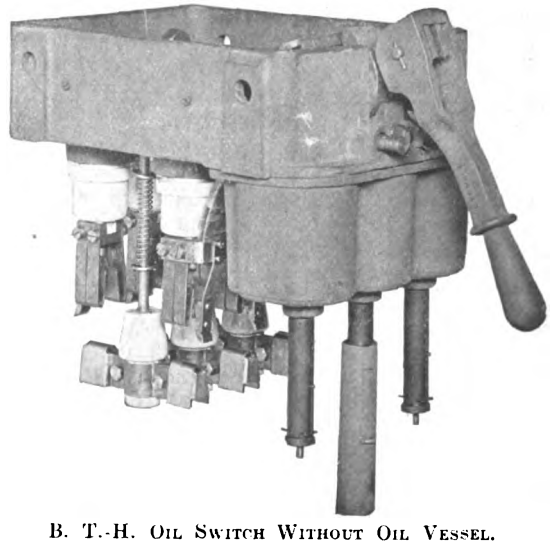
A good deal of the auxiliary machinery of the new 27 in. mill is electrically driven, although the main rolls are operated by steam. The live rolls, which are 38 in number, 2 ft. 9 in. wide by 2 ft. 6 in. in diameter, are driven by means of a 50 h.p. series-wound motor. The pitch between each roller is 5 feet, and the drive is obtained by means of a double series of shafting and bevel gearing, *i.e.*, the length of the live rolls is divided up into sections, each section being commanded by a second motion shaft bearing bevel wheels, gearing into similar wheels on the rolls. Each of these shafts bears a main bevel gear, gearing into the main driving shaft, which in its turn is connected to the motor. In this way the driving power is transmitted equally to all the rolls with a minimum of torsional effort on the section of shaft nearest to the motor, thereby cutting down from size and weight of shaft to be rotated and reducing transmission loss. This central strain system, with three speed reductions, has been found to give a peripheral speed on the circumference of the rollers of 300 feet per minute with very great efficiency. At each end of the roller path is a hydraulic switch for regulating the travel of the sections from one mill to the other as required.

Digitized by Google

Comparatively recently a new set of rolls has been erected, and the live rolls in connection with this machine are 6 ft. 9 in. long by 22 in. in diameter. A 50 b.h.p. motor drives nine of these live rolls, by means of a double reduction bevel gearing. The sections are taken from this mill along a series of 36 rolls, some of which are spaced 5 feet apart, with a dead roll alternating between each live roll, and driven by a 50 b.h.p. motor, to the saw for cutting the section to length. These rolls are each 24 in. in diameter and 33 in. wide. Another motor is used for part of the rack, but in the event of breakdown of the 50 b.h.p. motor an 85 b.h.p. series wound motor is capable of taking the whole set of rolls if necessary. The saw runs at a peripheral speed of 15,000 ft. per min., is 5 ft. in diameter, and 15/16 in. thick. It is driven by an 85 b.h.p. compound-wound motor. This is placed immediately behind the saw, and runs at 500 r.p.m. On each end of the shaft is mounted a pulley carrying a belt to a step-up series of countershafts, there being three increases in speed up to the saw spindle. The object of placing a belt on each side of the saw is to balance the strain on the machine by dividing the drive equally between each half of the length of its shafting. In connection with these rolls a collection of auxiliary machinery is electrically driven. Two 11·3 h.p. motors drive straightening machines for bars, while a 50 b.h.p. motor operates a straightener capable of straightening angles, channels tees, girders, and other shapes of sections required. A derrick crane has been converted to electric drive by means of mounting a 12 h.p. motor on the carriage of the crane, and driving the drum by means of worm gearing.

One of the recent additions to the company's plant has been the erection of an up-to-date girder shop, where group driving has been adopted. For example, a 11½ b.h.p. motor drives a group of four radial drills, and one grind-stone. Another motor of similar power drives a specially designed notching machine for work on the ends and flanges of girders. A 5 b.h.p. motor drives a group of three similar radial drills to those above described, while commanding the whole shop is a 3-motor five-ton crane, operated by motors of 12 b.h.p. for the lift and travel motions, and 6 b.h.p. for cross-travel. An electric brake is fitted for each motion in addition to the usual foot-brakes on the hoist and long travel. Other applications of electric power in the shop include a 11½ b.h.p. motor driving a cold saw, and the installation of small fans on the Blackman system for giving blast to the rivet fires. The distribution of power in this shop is typical of the system adopted throughout the works. The distribution board contains a series of switch fuses at the top of the board for controlling the lighting circuits in the shop, while the lower section of the board is reserved for similar gear for the larger capacities required. The wiring is carried out by means of rubber-covered conductors mounted on insulators.

On the bank is to be found a motor driving two cold saws, a 11½ b.h.p. motor driving a straightening machine of the hammer type, and a 25 b.h.p. motor driving a 24 in. straightener. In connection with this machine there is a 3 b.h.p. motor for working up the head of the straightener. A similar 3-ton derrick crane to the one above described has been converted to electric drive by means of the installation of a 12 h.p. motor. The live rolls on the 36 in. mill are operated in the same way as above described by means of a 50 b.h.p. driving 35 rolls of the same size as those on the 27 in. mill, while an 85 b.h.p. motor drives a 5 ft. 6 in. diameter saw, capable of dealing with girders up to 24 in. by 4½ in. and 10 in. rounds. Electric drive is also used for shears and punch. A series of electrically-operated cranes are to be found in this section of the plant, including a 50-ton crane on the 36 in. and 27 in. mill bay, similar cranes being installed for the fitting shop and the cogging mill. Electric drive is used in the pattern and joiners' shop, and in the fitting shop, one motor driving a lathe, circular saw, and band saw for the joiners' use, while a 50 b.h.p. shunt motor operates the machinery in the fitting shop. A 5 b.h.p. motor drives a jib vertical drilling machine, capable of taking up to 3 in. or 4 in. drills, while the portability of electrically-operated tools is shown by a 2-speed portable drill, capable of being used with either flexible or solid shaft, driven by a 1 h.p. motor permanently attached to it.



Space will not permit of the full description of all the electrically-driven plant in these works, but mention may be made of two saws and a straightening machine driven by a 11½ b.h.p. motor on the old 27 in. bank, 12 h.p. series motors driving the racks on the old 27 in. mill, and a 11·3 b.h.p. motor driving a test-bending machine and saw puncher for stamping the teeth in the saws used. In connection with the smaller mills a series of motors drive roller straightening machines, shears, &c., for both the 12 in. and 9 in. bays, and so excellent has been the performance of the electrical plant that it is proposed shortly to instal a 25 b.h.p. motor in connection with an 18 in. mill, in order to drive a circular hot saw by means of belt, this saw depending for its action on an exceedingly high speed, and having a plain edge. As the electric plant is fairly extensive, a repair shop has been erected on the works for the use of the electrical department, in order to undertake armature winding, brass work, and similar functions, which are being operated by a 5 b.h.p. motor. The lighting in the yard and works is carried out by means of electricity, about 140 arcs, ranging from the flame type to enclosed Jandus lamps, being installed, together with a large number of incandescents.

In concluding our description of this electrical equipment, we must acknowledge the courtesy of Mr. John Strain, the chairman of the Lanarkshire Steel Co., Ltd., for his permission for us to examine this equipment.

ENCLOSED OIL SWITCHES

TO meet the demand created by the extending use of three-phase alternating current for industrial purposes for totally enclosed oil switches for pressures up to 3,000 volts, the British Thomson-Houston Co., Ltd. (Rugby), has standardised a series of oil switches which can be fitted with any of the usual automatic accessories, and are designed particularly with a view to safety in the hands of unskilled workmen. A line of standard attachments has been developed, comprising overload trip-coils, with or without time-lag, no-voltage devices, and ammeters or voltmeters, suitable for mounting direct on the switch-cases. The accompanying illustration shows a switch from which the oil-container has been removed.

The contacts, trip-coils, and operating mechanism are all supported from a common frame, from which the oil-vessel is also suspended. The whole of the live parts of the switch are supported on porcelain insulators, and porcelain bobbins are used for trip-coils. The oil-vessel is lined throughout with specially treated wood, and is furnished with barriers of the same material, which are held securely in position between the poles of the switches. The joints between the cover and the frame and between the oil-can and the frame are so constructed that the whole switch is dust-tight and flame-proof. Each contact is made between a wedge-shaped copper blade and a double

B. T.-H. Oil Switch Without Oil Vessel.

set of self-aligning contact fingers. Sparking fingers of solid copper are provided in order to prevent injury to the main contact when opening circuits carrying large currents. These switches are opened or closed by a single motion of the operating lever, which is arranged so that both a quick make and break are obtained. The automatic switch mechanism is arranged so that if the switch opens automatically the operating lever remains in the closed position, thus the switch cannot be held closed on a fault. The tripping device comes into operation immediately contact is made and before the handle is fully closed. An indicator is provided independent of the handle to show when the switch is opened.

The overload release coils of these switches are contained in a separate iron casting bolted to the switch frame. The coils are wound on porcelain spools, and are thoroughly insulated. The overload trip devices can be supplied either with an instantaneous or with a time-lag device. The time-lag devices are of the oil dash-pot type, and are provided with a spherical plunger so as to prevent the possibility of jambing.

Damages Against Electrobus Co.—In the King's Bench Division last week, the London Electrobus Co. were ordered to pay £20 damages to a man named Bendry, who was injured through being knocked down by one of the company's 'buses in Fleet Street in November last.

THE ELECTRIC DRIVING OF PRINTING PRESSES

THE hearing of the action brought by Messrs. J. H. Holmes & Co. against the Associated Newspapers, Ltd., for alleged infringement of their patent for the electric driving of printing presses, was commenced on Friday last in the Chancery Division of the High Courts, before Mr. Justice Neville, and is still proceeding. Messrs. J. H. Holmes & Co. claim damages, an injunction against further infringements, and delivery up or destruction of all infringing machines in the possession or control of the defendants. The Associated Newspapers, Ltd., do not admit the alleged infringement, and further state that two claims of the patent in question are invalid, both on account of anticipation and lack of subject-matter.

Mr. A. J. Walter, K.C., and Mr. J. Hunter Gray are appearing for Messrs. J. H. Holmes & Co., and Mr. Astbury, K.C., and Mr. D. M. Kerly are appearing for the Associated Newspapers, Ltd. Mr. Dugald Clerk has given expert evidence on behalf of the former, and Mr. J. Swinburne was called on behalf of the latter party.

The patent in question is No. 9,802 of April 28th, 1898, and was granted to W. A. Clatworthy and W. H., A., J. H., L. W., and E. Holmes, all of J. H. Holmes & Co., of Newcastle-upon-Tyne. It describes a method of driving printing presses which gives a first slow-running speed, and a gradual acceleration until full speed is reached, without any shock. This is effected by employing two motors, a main motor driving the press direct, and an auxiliary motor connected to the main motor shaft through worm gearing and a free-wheel clutch, so that the main motor can overrun the auxiliary motor. A hand-operated controller causes the clutch to be thrown into gear electrically, and then starts up the two motors in succession. When the main motor overruns the auxiliary motor, the latter is automatically switched off.

The five claims of the patent, the first, second and fourth of which are alleged to have been infringed, read as follows:—

1. A system or method of electrically driving a newspaper printing machine or the like at very diverse speeds, consisting of the use of an auxiliary motor, in addition to, and driving by power gear through, the shaft of a main motor, both for the purpose of driving the printing machine at a slow and steady rate when required, and for starting the printing machine from rest, to enable the main motor to gather up power and drive without shock or excessive current substantially as described.

2. In an electrical driving device, a main motor coupled or geared direct to the main shaft of a driven machine, in combination with an auxiliary light motor, power-geared to the shaft of the main motor, and a self-releasing clutch between auxiliary motor and main motor shaft, disengaging and cutting out the auxiliary motor so soon as the main motor overruns the latter, substantially as described.

3. In an electrical driving device, consisting of the combination of an auxiliary and main motor, the combination with a clutch between the said motors, of an electrically operated device such as the core of a solenoid, to connect up the clutch, and which is adapted at the same time, when the clutch is drawn back by the main motor overrunning the auxiliary motor, to cut off the supply current from the auxiliary motor, and thus bring it to rest substantially as described.

4. In an electrical driving device, consisting of the combination of an auxiliary and a main motor, a combination-switch, operated by a single handle, adapted by one progressive movement to first start the auxiliary motor, and eventually when desired to start and regulate the speed of the main motor, and having electrically-held switches, controlling the supply current to the main and auxiliary motors which are adapted instantly to stop either or both the motors by the operation of stop-pushes, located where desired, or to break the supply circuit to both motors upon the failure of the supply current, substantially as described.

5. The arrangement and combination of parts and devices forming a system for electrically driving a heavy machine at an alternative slow speed with small power, or fast speed with full power, such as a newspaper printing machine or the like, substantially as described herewith and illustrated in the drawings annexed hereto.

To support the allegation of invalidity of the first two claims on account of anticipation, the defendants put forward five previous patents, three British and two American; these are as follows:—

The British patent No. 4,501 of 1879, granted to J. Robson, of North Shields, relates to the starting of large gas engines, and covers the use of a small auxiliary engine driven by gas under pressure stored in a reservoir. The small engine has a toothed pinion gearing into cogs on the main flywheel. No. 48 of 1883, granted to J. Musgrave and R. Gregory, of Bolton, covers a hand-controlled barring gear driven by an auxiliary engine. No. 4,387 of 1890, granted to J. and W. McNaught, of Rochdale, covers a gear by which the driving pinion of the barring engine is *automatically* thrown out of gear when the main engine has attained a certain speed. The U.S.A. patent No. 446,696 of 1891, granted to W. Scott, covers a driving mechanism for printing presses comprising fast and loose pulleys on the main driving shaft, and gearing with a friction clutch for driving the press in the same direction but at a slower speed when the belt is shifted to the second pulley. The other U.S.A. patent, No. 599,600, of February 22nd, 1898, granted to G. W. Dickie, covers a method of electrically operating gun turrets, in which two motors are employed, a small motor being geared through a train of wheels to the main motor. The small motor is switched on first, and current is only supplied to the main motor when it is running at its normal speed. When this is done, the current is simultaneously switched off the small motor, and a clutch is thrown out of gear so that the small motor comes to rest.

In addition to these patents, reference is made to descriptions of printing press equipments in the *Western Electrician* of Chicago, and the *Electrical Engineer* of New York, and to some early presses installed at the offices of the *Daily Mail*, the *Times*, the *Standard*, and the *Daily Telegraph* in London, previous to the date of the patent. These presses are stated to have embodied the idea of the auxiliary engine or other device for starting up. Reference is also made to a barring-engine installed in the works of Messrs. Musgrave & Sons at Bolton in 1893.

The equipments alleged as infringements are those installed about March, 1908, at the offices of the *Daily Mail* in Carmelite Street, and at the *Evening News* premises in Holland Street, Southwark, and also that erected in May, 1908, at the *Daily Mail* kiosk at the Franco-British Exhibition. A later and exactly similar equipment for the *Times* offices was described in ELECTRICAL ENGINEERING of June 3rd, 1909, page 506. These equipments were installed by Messrs. Kohler Bros., of 56 Ludgate Hill, E.C.

In the Kohler system for the driving of large octuple presses, such as those used in the above cases, the equipment consists of two 60 h.p. and two 10 h.p. motors for each press, and a four-motor controller with sixteen push-button control stations at various points about the press. The main 60 h.p. motor is coupled direct to an extension of the press shaft. A worm-wheel runs free on the main shaft, but carries a ratchet-wheel, which engages with pawls pivotted on a disc keyed to the press shaft. The rotation of the worm by the small 10 h.p. motor starts the worm-wheel and engages the ratchet with the pawls, and causes the machine to be driven at a slow speed. When the small motor has attained full speed, the main motor is automatically put in circuit, the pawls leave the ratchet free, and the small motor and worm-wheel are brought to rest. The small motor is used for operating at slow speed when dressing the press and leading in the paper web. The main motor takes up the load and overruns the small motor when operating at printing speed.

After Mr. A. J. Walter, K.C., had opened the case, Mr. Dugald Clerk was examined as the first witness for the plaintiffs. He pointed out how the overrunning of the small motor by the larger one was effected without any back lash of the gears by placing the motors in "mechanical series," that is, by gearing the small motor to the large motor, and the large one to the press. There were also other advantages from this arrangement, including the high ratio of reduction. He said that he did not find the Clatworthy invention described in any of the previous patents or in any previous publication or machine. There was a distinct invention in it, although it was only a small departure from previous knowledge. Mr. Clerk was then cross-examined by Mr. Astbury, K.C., as to the necessity for overrunning of the two motors, and as to whether some previous machines with belt and spur-gear driving respectively could be said to have the "mechanical series" arrangement. Mr. Astbury further referred to the *Western Electrician* of April 16th, 1898, placed in the British Patent Office Library on April 25th of that

Digitized by Google

year, which contained a description of a press driven by two motors, the smaller motor (coupled to the press shaft through worm gearing) being used when the press was required to be driven at a slow speed. The question as to whether the small motor was used for starting up was then argued, as the description included a statement that the large motor had series winding to give a large starting torque. Mr. Clerk agreed that from the description one might infer that the small motor was sometimes running when the large motor was started so that it was overrun by the latter. On Tuesday the cross-examination of Mr. Clerk was resumed, and after evidence had been given by three practical engineers connected with the printing trade as to the importance of smooth acceleration, &c., Mr. Hunter Gray made a statement as to the interpretation to be put upon the claims of the Clatworthy patent. Yesterday morning Mr. Astbury called upon Mr. J. Swinburne to give evidence, and the cross-examination of this witness is proceeding as we go to press.

THE "WULTUN" LAMP

THE British-made metal filament lamp which is sold under the name of the "Wultun" lamp is a tungsten lamp made under patented processes by the British Tungsten Lamp Co., Ltd., at their works at Huyton Quarry, near Liverpool. The company not only turn out complete lamps, but also supply filaments to other lamp-makers. Great care is given to the manufacture and testing of these lamps, and it is claimed that the filament is the strongest and most reliable tungsten filament on the market, with an average life of over 1,000 hours on alternating or continuous current when used in any position. Considerable extensions to the works are being put down to deal with the increasing demand.

The 100-volt lamps from 16 to 25 c.p. are in pear-shaped bulbs $4\frac{1}{2}$ in. by $2\frac{3}{8}$ in., and even the bulbs of the 200-volt lamps, which are made from 30 c.p. upwards, do not exceed $5\frac{1}{2}$ in. overall length and $2\frac{1}{2}$ in. diameter. 25-volt lamps of 10 c.p. and 16 c.p. are made in pear-shaped bulbs, and also a special series of 24 and 30 volt lamps in very neat small round bulbs for train lighting. There is also a series of 50/60-volt lamps ranging from 12 to 32 c.p., and the largest of the high-voltage lamps listed is 60 c.p. An efficiency of 1 watt per candle-power is claimed for all sizes.

WIRELESS TELEGRAPH NOTES

The *Telephone Engineer* (Chicago) states that the Union Pacific Railway are about to erect a large wireless station at their works at Omaha, from which to carry out experiments with a view to the establishment of a service of wireless telegraphy, and more particularly telephony, to and from moving trains.

An article in the *Electrical World* gives some particulars of the wireless telegraph systems used in the United States Navy. Experiments have been carried out with most systems prominent in America except that of Marconi, of which the only example is on a revenue cutter. Shoemaker, De Forest, Fessenden, Stone, and Telefunken apparatus is largely used, and there are a few Pierce sets. The majority of the installations are from 2- to 5-kw. capacity, but a 25-kw. Fessenden outfit is being installed on the *Connecticut* for communication with the high power shore stations, which the Fessenden Company are erecting for the American Navy. Many of the sets are of composite character. Shoemaker and De Forest transmitters are largely used in conjunction with an air blast spark-gap designed in the navy yards. The detector used almost universally now on the battleships is the carborundum or perikon, or both. The electrolytic type of detector, while being very sensitive, is not found to be so suitable for fleet work. The carborundum gives splendid results when properly handled, it being impossible to destroy its sensitiveness by strong sparks or static electricity; on the contrary, it seems to improve: however, for long-distance work it cannot come up to the perikon. The perikon and a very fine wire electrolytic detector are of about the same sensitiveness. The perikon soon becomes dead, however, from strong sparks or static electricity, although recovering by being given a short rest. The best combination seems to be the caborundum for short distance and the perikon for long distance. Flat-top loop aerials of the L-shape are used almost exclusively, the grid being made up from 4 to 10 phosphor-bronze wires strung 18 in. apart.

The P. & O. steamer *Mantua*, which, as we announced last week, is the first of this company's boats to be fitted with wireless telegraphy, has been in constant communication with two of H.M. cruisers during her voyage to Bombay. The Indian Government have erected a wireless station at Bombay, and the *Mantua*, which will be the first steamer to make communication with this, expects to do so two days before arrival.

The Council of the London Chamber of Commerce propose, on the advice of their electrical section, to ask the Government to introduce a short Bill making it compulsory that all ocean-going passenger vessels shall be fitted with wireless telegraph apparatus.

The Admiralty have decided to erect a wireless telegraph station at West Bank, close to Wick, N.B.

ICE-MAKING PLANTS FOR IMPROVING THE LOAD FACTOR

THE supply of power to ice-making works or plant for that purpose in the power station itself during the non-peak hours, has often been suggested as a practical method of flattening the load curve, and has been practically carried out, both in this country and abroad. Some notes on a suitable refrigerating plant for producing the rapid freezing necessary to complete the formation of large blocks of ice during the comparatively short periods of low loads in power stations, were given in ELECTRICAL ENGINEERING, January 7th, 1909, page 13.

American and Canadian power stations, in particular, appear to be putting the idea into practice, and the following particulars from the *Electrical World* of one or two such schemes are of interest:—

The Light, Heat, & Power Company, of Montreal, for example, has announced that it intends to install an ice-making plant in connection with its electricity supply system. The proposed plant will cost between £25,000 and £30,000, and commercial ice will be sold at a much lower price than at present. It is understood that a similar scheme has been proposed to the directors of the Winnipeg Electric Company, at Winnipeg. In the latter city, power is as cheap as in any Canadian city, and ice is as dear as anywhere, despite the cold winters.

In order to encourage the electric working of refrigerating plants in New Jersey, the Public Service Corporation of that State gave a large demonstration of refrigerating and ice-making plant in operation last month. The company has made a special rate for energy supplied for this purpose, and the result of this has been that several large installations are now being supplied from the central stations in the larger cities of New Jersey. Next year further encouragement will be given, and the manufacturers of refrigerating plant will be invited to co-operate in the work. The majority of the present installations are in use 10 hours each day. This load comes on early in the day, and is thrown off just before night. The storage boxes are kept closed all night without undue drop in temperature. An automatic device regulates the apparatus so as to keep an even degree of temperature at all times. While the first cost of an electrical refrigerator is considerable, the owners are said to be satisfied with the saving accomplished over ice cooling.

Another American company which has taken the matter up is the Sterling Consolidated Electric Co. of Sterling, Colorado. This company has just completed a combined ice-making and electric-light plant, but instead of employing electrically worked refrigerating machines, steam-driven machines supplied from the same boilers as the electric generators, are used. Two 175-h.p. water-tube boilers are installed, with space for a third, and an electrically driven fan operates an induced draught installation. The electrical equipment consists of one 150-kw. and one 75-kw. generating set. The steam feed pipes from the boiler-room enter one main pipe steam line, which also feeds steam to a 20-ton refrigerating machine, driven by a Corliss engine. Space is allowed also for another ice machine of the same rating, as well as for another generating unit of the larger rating. The company has installed its own artesian well, and uses the exhaust steam for its distilled water supply. The circulating pump, electrically driven, is used for ammonia condensing and steam condensing.

Certificated Electrical Wiremen.—The Electrical Contractors' Association of Australia and the Electrical Employees' Union have agreed upon making endeavours to secure the appointment of a wages board for the trade, and when this is formed, conditions will be arranged upon which licences will be granted to electrical wiremen.

Manchester Students' Section, I.E.E.—The 1909–10 session of the Manchester Students' Section of the Institution of Electrical Engineers will be opened with a supper and smoking concert at the Mosley Hotel, Piccadilly, Manchester, at 7.30 p.m., on Tuesday, November 9th. The ordinary meetings of the section will be held as usual at the Municipal School of Technology, Sackville Street, Manchester.

Standardisation of Engineering Publications.—Some few months ago we called attention to the formation of the Engineers' Standardised Publications Association, with the object of effecting reform in regard to the standardisation of manufacturers' price lists and other literature. We now learn that the scheme has met with some considerable degree of support, and a list of some of the more prominent men who have joined the association includes the names of the central station electrical engineers of the country. With this encouragement the association proposes to proceed actively with its scheme, and is approaching engineering firms with a view to arranging for the issue of their lists, &c., in the standard size and form recommended, so that they can be collected together, filed, or bound in standard cases. A card index forms a part of the scheme. The association will supply the files and index case to its subscribers, and will undertake the issuing of manufacturers' lists to them. The advisory committee consists of Mr. A. H. Dykes, Mr. T. W. How, Mr. H. M. Savers, and Mr. W. H. Booth. The secretary is Mr. J. D. Barton Innes, and Mr. John I. Hall is technical manager. The offices are at Craven House, Kingsway, W.C.

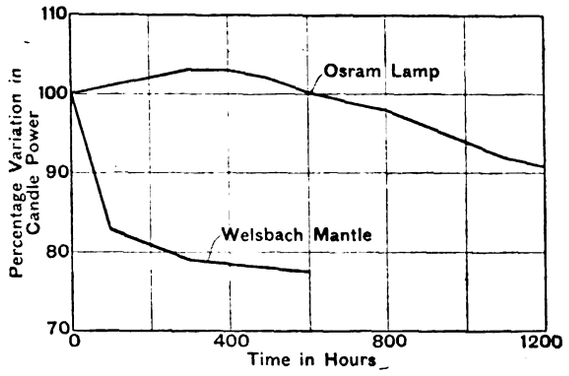
ELECTRICAL MANUFACTURERS AND THEIR AGENTS

A COMPLICATED case of some interest to electrical manufacturers in connection with their agencies was heard before Mr. Justice Ridley and a special jury in the King's Bench Division on Monday and Tuesday. In this, the Armorduct Manufacturing Co., Ltd., sued the General Incandescent Co., Ltd., for the return of moneys alleged to be due to the former, but paid to the latter by a man named Haynes, who was at one time agent to the Armorduct Co. The facts are as follows:—The Armorduct Co. had an agreement with Haynes to act as their agent in Nottingham and district on commission, but in 1906 it came to the knowledge of the company that Haynes was selling the goods on his own account and not in the name of the company. The agency agreement was therefore terminated in December, 1906, and when the accounts between the parties were settled up, Haynes admitted that he owed the company about £160 for goods which he had not accounted for. He was subsequently sued for this, and judgment obtained against him, but the money has never been recovered. In April, 1906, Haynes became district manager in Nottingham to the General Incandescent Co., Ltd., and the terms of his agreement were that he should pay all moneys received by him into the company's banking account at Nottingham. Mr. W. Schmahl, managing director of the Armorduct Co., stated in evidence that during a visit to Haynes at Nottingham a piece of paper came into his hands which showed clearly that Haynes had paid certain sums amounting to £59 into the defendants' bank which were undoubtedly received for the sale of Armorduct goods sent to Haynes on sale or return.



This paper was handed up to the Judge, who, after examining it, expressed the opinion that the account was so made out as to render all defence to the action hopeless, an expression of opinion which called forth protests from the defending counsel, Mr. Thomas, K.C., on the ground that the Judge had not heard their explanation of the document. So emphatic was the Judge on the point that some strong expressions passed between the counsel for the defence and himself, the former eventually being reminded that he was making remarks disrespectful to the Bench. From this point, *i.e.*, on Monday afternoon, it was clear that the Judge had made up his mind; in fact, he frequently remarked that the defence was wasting time in going on. Nevertheless, the case continued until Tuesday afternoon, the defence being that Haynes was entitled to mix the various moneys which he received on behalf of a number of principals for whom he was acting, and to pay one principal, if he thought fit, with the money received as the result of the sale of goods belonging to another principal. Thus each principal had to recover against Haynes. In his summing-up, however, his Lordship said the whole case turned upon the account put in evidence by Mr. Schmahl, and which had been prepared by the instructions of Haynes. This showed the various amounts received for Armorduct goods, and also that in most cases the sums had been paid over to the General Incandescent Co., Ltd., with the knowledge of the latter. The jury returned a verdict for the plaintiffs, and judgment was entered for £59, with liberty to inspect the defendant's books with a view to ascertaining whether any further sums had been so paid over. A stay of execution for seven days was granted.

The "Electron."—The September issue of this monthly, the official organ of Siemens' Stafford Institute, has as a frontispiece a photograph of the large machine shop at the Stafford works. A portrait of Mr. F. E. Read, the Hon. General Secretary of the Institute, is also included. Among the articles is an illustrated description of the sewage disposal plant at Maidstone, and the conclusion of Mr. Read's description of the large Siemens' works in Germany, comprising some notes on the Charlottenburg and Nonnendamm works. A photograph of a group of fifty-five employees who have been in the service of the English firm for fifteen years or more, is accompanied by a few notes on their respective careers, and there is a short article describing some incidents in connection with the recent disturbances in India. Reports of the work in the various sections of the Institute conclude this issue.

Prosecution of Mine Managers.—Judgment was given on Thursday with reference to the preliminary point raised concerning the prosecution of Mr. C. A. Carlow, manager of the Fife Coal Co., and Mr. W. E. Richardson, manager of the Foulford Pit of the company. As stated in our last issue, these two officials are charged with knowingly allowing defective electrical apparatus in the pit in question, but objection was taken to the wording of the charge for the reason that neither of the defendants were directly responsible for the condition of the machinery. Objection was also taken to the want of definite instructions from the local inspector as to what he required to be done under the rules for the use of electricity in mines. The Sheriff, however, found that the objections were on the merits of the case, and fixed November 18th for the hearing of the trial.

METAL FILAMENTS AND GAS MANTLES

IN the course of a Paper entitled "Modern Illumination," by Mr. E. G. Kennard, published in the *Post Office Electrical Engineers' Journal*, are given the comparative curves reproduced herewith of percentage

VARIATION OF CANDLE-POWER DURING LIFE OF AN OSRAM LAMP AND A WELSBACH MANTLE.

variation of candle-power during useful life for a Welsbach gas mantle and an Osram lamp. The author states that the curve for the gas mantle is the average of several tests published by Dr. Bohm. The difference is remarkably striking.

EAST LONDON ELECTRICAL EXHIBITION

THE exhibition promoted by the Metropolitan Boroughs of Hackney, Shoreditch, and Stepney, to encourage the use of electricity for power, lighting, and other purposes, was opened by Mr. W. M. Mordey on Monday last. In declaring the exhibition open, Mr. Mordey referred to the fact that co-operation in the three Boroughs was easy, as the systems of supply were identical. Though the average price paid per unit for the whole of London was, he said, 2·9d. the same figure for these three Boroughs worked out at 1·85d., and under these conditions the development of the supply should be rapid.

The most effective stands in the exhibition are those of Messrs. Simplex, Ltd., and Messrs. Siemens Bros. & Co. The former have an attractive array of electric light fittings, cooking and heating appliances (these being shown in operation), while the whole exhibit is a demonstration of the simplicity and adaptability of the Simplex steel wiring conduit. A number of small motors for industrial and domestic work are shown, and the stand is well illuminated with Simplex metal filament lamps. Switches, fuse-boxes, and other accessories are also well represented. The Siemens' stand comprises a collection of dry cells of various kinds, panels to illustrate wiring on the O.-S. system, motor-driven grinders for fixing to lathes, and a portable vacuum cleaner with a rotary pump driven by a 1-h.p. motor. A 2-h.p. portable and 2 to 5 h.p. stationary cleaners can also be obtained. There is a good show of tantalum lamps, and it is interesting to note that when, by an accident on Monday, over 200 of the 240-volt tantalum lamps were subjected to a pressure of 480 volts for some few seconds, only 21 were burnt out. On a separate stand a representative collection of Siemens' instruments and instrument transformers is exhibited; this includes an instrument for testing lightning conductors by means of a telephone, and a direct-reading ohmmeter for shop use.

The exhibit of Messrs. Marryat & Place (28 Hatton Garden, E.C.) is certain to attract much attention. A 500 amp. Moissan arc furnace, capable of raising the carbon crucible placed between the electrodes to a temperature of over 7,000° F., is being shown in operation, and a demonstration of armature winding is also being given. Other items include a model push-button lift, electric drills with magnetic pillars, and grinders, all shown at work. An electric hoist is used to manipulate the heavy cover of the Moissan furnace. Messrs. G. J. Worssam & Son (Wenlock Road, City Road, N.) exhibit an electrically-driven refrigerating plant suitable for an hotel or a country house. A novelty in the way of electric winches is shown by Messrs. Tyler & Freeman (20 New Bridge Street, E.C.). This is designed for warehouse, marine, or other work, and will lift 12 cwt. at a speed of 150 ft. per minute. The outer frame of the motor field system forms the winding barrel, and the armature revolves at a fairly high speed within it, being geared to the field system through simple epicyclic gear, which reduces the speed of the barrel to about 25 r.p.m. The armature is mounted on a hollow sleeve with ball bearings, and the field system and barrel is also provided with ball bearings, these giving the winch high efficiency. An ordinary crane controller is used to start and reverse the winch. A motor-driven fan,

Digitized by Google

suitable for ventilating or for induced draught for boilers, is also shown.

Messrs. Ferranti, Ltd. (106 Queen Victoria Street, E.C.), have a selection of motor-starters with carbon resistance units which cannot be burnt out, and also show some ironclad fuse-boxes on the "unit" system. Motors, circuit-breakers, and instruments are also exhibited. The National Boiler & General Insurance Co., Ltd. (22 St. Ann's Square, Manchester), show a number of boiler fittings, fusible plugs, &c., and are distributing pamphlets calling attention to the benefits to be derived from insurance against accidents of boilers, engines, and electrical machinery of all kinds, as well as starting switches and controllers. Photographs of some remarkable breakdowns are on view.

Mr. Haydn Harrison (11 Victoria Street, Westminster, S.W.) exhibits a number of lanterns for street lighting with metal filament lamps, including that used in Marylebone. Most of these include the patent switch-fuse described in ELECTRICAL ENGINEERING of June 24th, page 590, and a patent anti-vibration lamp holder comprising a socket supported radially by three spiral springs from an insulating collar of vitrite. The Thorpe Meter Syndicate, Ltd., have a number of electrolytic meters, and an example of the electrolytic time-limit relay on view. These were described in detail in our issue of last week. Messrs. J. G. Ingram & Son (Hackney Wick, N.E.) exhibit a moulded rubber plough base as used on the L.C.C. conduit tramway system, and also a number of rubber gloves. An interesting stand is that of the Reason Manufacturing Co., Ltd. (Brighton), on which can be seen a number of small arc lamps and metal filament lamp lanterns for street lighting. Time switches, of the hand- and electrically-wound patterns, and switch-fuses for use in street lighting, are also shown. A novelty is a combined meter and fuse box, comprising a miniature type electrolytic meter, two house-service fuses, and a sealing trough, all combined in one iron case. The meter has a separate inside cover allowing it to be sealed up separately. Demand indicators and prepayment meters are also exhibited.

Among the other exhibitors are Messrs. Purcell & Nobbs (87 Cleveland Street, Fitzroy Square, W.), who show their "Electroyl" radiators; Messrs. Rashleigh Phipps & Co., who have an example of their new kaleidoscopic sign; and Messrs. Pooley & Austin (25 Victoria Street, S.W.), who exhibit a "Therol" heater, several Mawdsley motors, and some "Direkon" starters. Messrs. Lambie, Wrigley & Co. (116 City Road, E.C.), and Messrs. R. Becker & Co. (53 City Road, E.C.), have representative exhibits of machine tools, and Messrs. Babcock & Wilcox, Ltd., show models of boilers, mechanical stokers, &c.

ELECTROMETALLURGY AND ELECTROCHEMISTRY

THE platinising of metals is one of the most difficult of electro-plating operations, partly because there are few solutions which give satisfactory deposits, and these require very careful watching and regulation. But even when one has a bath which in itself is satisfactory, it is very difficult to obtain deposits of any thickness. Furthermore, electro-deposited platinum shows a very great tendency to scale off, particularly at high temperatures. If a really satisfactory and moderately thick deposit of platinum can be produced upon base metals, then these could be employed in many cases in place of the very expensive platinum. In the *Elektrochemische Zeitschrift* of September a process is described by Max Baum which is said to yield very satisfactory results. In fact, wires of nickel, iron, &c., coated in the manner recommended, can, so the author says, be melted into glass. The usual method employed for plating on iron with platinum is to first coat it with copper, but when so coated the objects cannot be exposed to high temperatures. The new process is to employ mixed baths of salts of the metal upon which it is desired to plate and of platinum. For example, it is desired to deposit platinum on nickel wire. A bath is made up, containing 25 per cent. of platinum and 75 per cent. of nickel; a current of from 0·6 to 0·8 ampere per sq. decimetre (5·6 to 7·2 amperes per sq. foot) at from 4 to 6 volts is employed, and a deposit containing a small quantity of platinum and a large quantity of nickel is obtained. The wire is then taken out of the bath, washed, and dried, and is then heated in an atmosphere of hydrogen to from 900° to 1,000° C. After sufficient heating it is placed in a second bath containing 50 per cent. nickel and 50 per cent. platinum, and the current again passed; it is then again heated in the hydrogen atmosphere. The process is again repeated, employing a bath with 75 per cent. platinum and 25 per cent. nickel. It is now coated with a layer which is chiefly platinum, the heating in hydrogen is repeated, and then the wire placed in a platinum bath containing no nickel. By taking out of the bath at intervals and heating as before, deposits of any required thickness can be obtained. The wire now consists of a centre of nickel coated concentrically with increasing platinum rich alloys of nickel until the final pure platinum deposit is reached. It is claimed that to a certain extent the hydrogen unites with the metal and causes the surface to be slightly roughened: thus the next deposit holds better than on an absolutely smooth surface.

As a rule, electro-deposited iron is extremely hard and brittle, and requires to be very strongly heated to drive off the occluded hydrogen and render it malleable. In the *German Patent* 212,994 (1908) a method is described for producing iron sheets or tubes which gives iron directly in the malleable condition. The chief point about the patent appears to be the addition of large quantities of a hygroscopic salt to the bath, so that its temperature can be raised above 100° C. It certainly strikes one that the employment of a bath at such high temperatures would present considerable difficulties in practice. The following quantities are given:—500 grm. calcium chloride, 450 grm. ferrous chloride, and 750 cubic centimetres of water. Such a bath can be heated to a temperature of 110° C. The current employed is given as 20 amperes per sq. decimetre (182 amperes per sq. foot).

It is well known that for many purposes—for example, the coating of iron with copper—an acid copper bath is out of the question, and generally what is called an alkaline bath is employed—that is to say, a cyanide bath. In the September number of the *Elektrochemische Zeitschrift* the following receipts are given:—

	Cold bath.		Hot bath.	
	For iron and steel, grams.	For tin, cast iron and zinc, grams.	For iron and steel, grams.	For small zinc articles, grams.
Neutral copper acetate ...	1900	1400	2000	1800
Liquid ammonia (sp. gr. 0·96)	1400	800	1200	600
Soda crystals	4000	—	2000	—
Pure sulphite of soda	2000	1200	800	400
Pure potassium cyanide...	2000	2000	2800	2800
Distilled water.....	100 kg.	100 kg.	100 kg.	100 kg.

In Bavaria the Government have been for some time considering the question of the amount of available water-power which can be employed for industrial purposes. It is calculated that 500,000 h.p. can be taken from the rivers without presenting any particularly difficult engineering problems, and without much trouble this could readily be increased to 700,000 h.p. It is intended to first of all tap the 500,000 h.p., and of this 100,000 h.p. is to be used by the various towns for power purposes, lighting and street tramways, or for railway purposes. The remaining 400,000 h.p. to be employed for industrial purposes. It is intended in the first place to utilise the power from the Alz and Lake Walchensee.

From the October number of *Electrochemical and Metallurgical Industry* we learn that negotiations for an electric iron-ore reduction and steel plant in Canada are well advanced. It is intended that the first plant shall have a capacity of 5,000 h.p. The following is taken from an interview with Mr. Assar Grönwell, one of the three inventors of the furnace. The furnace, reported upon by Dr. Haanel, Director of Mines, Ottawa, has been working continuously for three months, until a strike caused it to be shut down. There has been absolutely no trouble with the electrodes. In the three-phase furnace two of the electrodes were at times removed for demonstration purposes, but one of the three was intentionally never removed, and remained in a satisfactory condition for six weeks. At the end of the time it was adjusted, and was able to stand another six weeks' run.

The electrodes are immersed in the charge, but do not dip through into the molten iron at the bottom of the furnace. When the furnace is tapped the ammeter shows no movement, which proves that practically no current passes through the molten iron at the bottom.

One point which Mr. Grönwell particularly emphasised is that the combination of an electric reduction furnace with electric steel furnaces is an important factor, because it is easy to make in the electric furnace a pig-iron with about 1 per cent. of carbon. By transferring the molten pig-iron directly to the electric furnace, the time necessary for getting the desired quality of steel is much less than with the present electric steel refining practice. He says that this is a very important point, because the elimination of the carbon in the reduction furnace is very important, since the comparatively long time necessary in the present electric steel furnace for reducing the carbon content is completely saved. From the three months' running of the furnace they are of the opinion that it will work efficiently on a large commercial scale.

Glasgow Section, I.E.E.—The eighth annual dinner of the Glasgow Section of the Institution of Electrical Engineers will be held in the Banqueting Hall of the "Grosvenor," Gordon Street, Glasgow, on Wednesday, December 1st. The meetings of the section will, as usual, be held on the first Tuesday in the month at 207 Bath Street, Glasgow, and among the Papers which have been arranged for, are the following:—December 14th, "Continuous Current Boosters and Balancers," by W. A. Kerr; January 11th, "The Most Economical Vacuum for Turbine Power Stations," by R. M. Neilson. The Students' Section will hold their meetings at the Glasgow Technical College. Mr. H. A. Mavor, the chairman of the Students' Section, delivered an address to the students last week, and dealt with the question of the electrical propulsion of ships.

AGREEMENTS UNDER THE LONDON ELECTRIC SUPPLY ACT, 1908

THE Highways Committee of the London County Council have reported that two agreements have been made by electric supply companies under the London Electric Supply Act, 1908, but inasmuch as the Committee are not satisfied that the agreements in question are such as were contemplated by the spirit of the Act of 1908, the Board of Trade is asked to make certain amendments in them. It may be remembered that under section 3 of the London Electric Supply Act, 1908, any of the electric supply authorities in London may, with the approval of the Board of Trade, enter into and carry into effect agreements for mutual assistance in regard to the following purposes, viz.: (1) The giving and taking of a supply of electrical energy and the distribution and supply of electrical energy so taken. (2) The management and working of the generating stations or of any part or parts of the several undertakings of the contracting parties. (3) The appropriation and division of receipts arising under and the provision of capital required for carrying into effect any such agreements. (4) Any matters or things incidental to or connected with any of the purposes aforesaid.

The agreements entered into are as follows:—(1) Between the London Electric Supply Corporation and the St. James' and Pall Mall Electric Light Company. (2) Between the London Electric Supply Corporation and the Westminster Electric Supply Corporation.

A third agreement has been entered into between the South Metropolitan Electric Light & Power Company and the West Kent Electric Company, under section 10 of the Blackheath and Greenwich District Electric Light Company's Act, 1903, and this is dealt with later.

By the first two agreements the London Electric Supply Corporation, whose undertaking is purchasable by the Council in 1931, proposes to make certain arrangements with two of the companies whose undertakings are not at present covered by the purchase clause of the 1908 Act. The effect of these agreements is briefly as follows:—The agreement with the Westminster company provides for the London company placing the management and working of that portion of its undertaking which is within the Westminster area in the hands of the Westminster company. The agreement defines the nature of the works to be so transferred, and provides for the London company renewing and repairing the same and carrying out any necessary additional works. The Westminster company is to pay to the London company each year until August 26th, 1931, a sum equal to 86 per cent. of the gross amounts received by the London company from its consumers in the Westminster area for the year 1908. In addition, the Westminster company is to pay the London company for all electrical energy supplied to it in pursuance of the agreement £2,000 a year to meet the standing charges of the London company for the maintenance, renewal, and up-keep of the works which are, under the agreement, placed in the hands of the Westminster company; and also a sum of 0·85d. for each Board of Trade unit of electrical energy supplied. The Westminster company is also to pay to the London company the net cost of labour and materials required for additional works and for maintaining and repairing additional mains, &c., to be provided by the London company, with the addition of 10 per cent. upon such net cost for supervision and use of tools. There is a provision in the agreement for the supply under certain conditions by the London company of electrical energy in bulk to the Westminster company. The agreement is to remain in force until the purchase of the undertaking of the London company and the Westminster company by the local authority or other body authorised to purchase the same; and the amount received by the London company from the purchasing authority as the purchase price of that portion of its undertaking which at the date of purchase shall be within the Westminster company's area, shall be paid over to the Westminster company. The terms of payment by the St. James's company vary somewhat, and there are other minor differences, but, so far as the Council is concerned, these do not appear to affect any action which it may be called upon to take.

The Committee do not think that clause 3 of the Act of 1908 contemplated what is practically tantamount to a transfer by one company of its undertaking to another company. They recommend, therefore, that the Board of Trade be asked to consider whether the proposed agreements fall within the scope of section 3 of the London Electric Supply Act, 1908; and that in the event of the Board deciding to approve the agreements, the following amendments should be made, viz.:—The insertion of a clause to provide for the termination of the agreements in 1915, unless in the meantime legislation shall be passed constituting the Council as the purchasing authority of the undertakings of the Westminster Electric Supply Corporation and the St. James' and Pall Mall Electric Supply Corporation. The insertion of such a clause as may be considered necessary to ensure that the interests of the consumers in the areas affected by the agreements shall be fully safeguarded.

With regard to the agreement between the South Metropolitan Electric Light & Power Company and West Kent Electric Company, this provides simply for the supply by the South Metropolitan Company to the West Kent Electric Company of energy required for the supply to customers of the West Kent Company "within, or for use and distribution within, the West Kent area of supply." The question of purchase, however, arises here also. The South Metropolitan Company's undertaking is purchasable by the Council, and the Committee think there should be provision for the determination of the agreement in 1931 if the Council decides to exercise its powers in that year. There is also the point that, in order to give this supply, the South Metropolitan Company may be compelled to provide works which are not required for the purposes of supply in its London area. The Committee recommend to the Board of Trade in this case the insertion of a provision for the absolute determination of the agreement in 1931 if the Council shall have given notice of intention to purchase the undertaking of the South Metropolitan Electric Light & Power Company in 1931. The insertion of a provision that the South Metropolitan Electric Light & Power Company shall take effective steps to show separately in its accounts all amounts spent in respect of works required for the supply of energy under the proposed agreement is also proposed.

LOCAL NOTES

ABERDEEN: *Supply to Tramway Company.*—We recently announced that the Aberdeen Suburban Tramway Co. had refused to accept the award of Mr. W. H. Patchell as to the price which the company should pay the Corporation for electrical energy. In order to avoid litigation over the matter, the Electricity Committee have appointed a sub-committee to name a price with the object of arriving at an amicable arrangement with the company.

BARNES: *Electric Wiring.*—Maidstone Electricity Department have asked if Barnes will assist in the promotion of a Bill for free, assisted, or hire wiring. It was resolved to reply in the affirmative provided that the contribution of Barnes should not exceed £30. To enable local wiring contractors to advertise electric heating and cooking apparatus they are to be charged in future at the flat rate of 1½d. per unit, provided their displays of fittings are satisfactory.

BRAZIL: *Electrical Imports.*—A British Consular report, dealing with the trade of Brazil, 1908, states that the electrical imports amounted to £543,850, compared with £707,054 in 1907. These two years show a large increase over 1906, when the imports only amounted to £288,036, but this is due, in great part, to the work of the Rio de Janeiro Electric Light & Power Co., although quite apart from this special case there is said to be a large and growing trade in electric lighting and power machinery in Brazil.

BRIERFIELD: *Tramway Lease.*—It has been resolved to offer, without prejudice, to the Burnley Corporation a further lease of the tramways undertaking, on a seven years' lease, at £1,200 per year.

BRITISH COLUMBIA: *Railway Company's Workshops.*—The British Columbia Electric Railway Co. are building a large car shed in New Westminster, above which will be situated the company's head offices. Plans have also been prepared for the erection of a large car-repairing depôt in the same town.

CANADA: *Explosion at Electricity Works.*—It is stated that the municipal electric light and waterworks at Aylmer, Ontario, were completely wrecked last week by a boiler exploding, the damage being estimated at £40,000.

CROYDON: *Electrical Inspector.*—The Board of Trade have appointed Dr. Alexander Russell, Principal of the Electrical Standardising, Testing, and Training Institution, to be electric inspector under the Croydon Corporation Electric Lighting Order, as successor to Mr. H. E. Harrison, who died in August.

EDINBURGH: *Proposed Electric Tramways.*—A proposal has been placed before the Corporation for the construction of electric tramways between Edinburgh and Queensferry, including an offer to make terms with the Cable Tramway Co., in Edinburgh, for the reconstruction of certain of the northern lines for electric traction. Detailed consideration of the proposal has been deferred until the appointment of the new Tramways Committee. Messrs. Buchan & Hogarth, consulting engineers, of Edinburgh, are connected with the proposal.

GRASSINGTON: *Electric Supply.*—The Council's generating station is now complete, and current for street lighting is being

Digitized by Google

supplied. The official opening will take place in the course of a week or two.

HALESOWEN: *Tramways.*—At the last meeting of the Council, the Clerk reported that considerable progress was being made with the scheme for the construction of light railways. In fact, he thought he could say that the work would be put in hand very shortly.

KINGSWINFORD: *Electric Light.*—The Board of Trade have appointed Mr. W. R. Sheldon, of Lincoln's Inn, London, to determine some matters in dispute between the Council and the Midland Electric Corporation for Power Distribution.

LONDON: *London County Council: Heat Coils and Fuses in Telephone Exchanges.*—The Council has approved the payment of £10 to the Tramways and Railways Association as a contribution towards the costs of the recent arbitration to determine whether tramway authorities or the Postmaster-General should bear the cost of installing heat coils and fuses at telephone exchanges.

London County Council: Tramways.—The Highways Committee recommend application to Parliament for an extension of time for the construction of the tramways from Hammersmith to Harlesden, and also the line along Wimbledon Road, authorised in 1903.

At the usual weekly meeting on Tuesday the annual report dealing with the Council tramways accounts was considered and eventually adopted. This report was given in ELECTRICAL ENGINEERING for July 22nd, p. 666. Sir John Benn moved that the report be referred back with instructions to the Committee to amend the accounts in order to show the amount of obsolete capital due to the abandonment of the G.B. system in the Mile End Road, but the amendment was rejected by 60 votes to 37.

City of London: St. Paul's Bridge.—The proposal of the Bridge House Estates Committee of the City of London Corporation for the construction of a new bridge across the Thames from the Southwark Bridge to a point near St. Paul's Cathedral, is to come up for discussion at an early meeting of the Corporation. The proposed new bridge, which will accommodate tramways, is estimated to cost £1,646,983.

Street Lighting.—The Streets Committee propose that they be authorised to carry out further experiments with street lighting, in accordance with the recommendation contained in their report upon this subject (ELECTRICAL ENGINEERING, July 15th, p. 645). The proposal will come before the Corporation to-day.

Stepney: New Power House.—The Blyth's Wharf Generating Station is to be opened by the Mayor on the 27th inst., when any machinery that may be ready for use will be set in motion by the Mayoress.

LOWESTOFT: *Tramways.*—The Town Clerk is to interview the Board of Trade with regard to the possibility of an extension of time for carrying out the East Anglian Light Railway Order, which expires on January 30th next.

MANCHESTER: *Tramway Receipts.*—The Tramways Committee reports that the receipts from the tramways for the half-year to September 30th were £4,000 less than in the corresponding period of last year.

Theft of Electrical Goods.—An employee of Messrs. Baxendale & Co., of Manchester, named E. Wilson, was charged last week with stealing electric lamps, telephone wires, &c., to the value of £500, and three other men were charged with receiving the goods.

MUSSELBURGH: *Street Lighting.*—A few weeks ago, an offer by the Musselburgh Electric Light & Traction Co. to undertake the public lighting, was accepted, but at the last meeting of the Council this decision was rescinded in consequence of the fact that the acceptance of the offer was carried at a meeting of only four members of the Council. The Electric Lighting Co. is to be asked for better terms.

NAVAN (Ireland): *Electric Lighting.*—It has been decided to apply to the Board of Trade for an electric lighting provisional order.

NEWCASTLE-UNDER-LYME: *Electricity Accounts.*—The accounts for the year to March 31st show a loss of £40 after meeting capital charges. This brings the total deficiency on the undertaking to £146.

PORT GLASGOW: *Electric Lighting.*—The Town Council have appointed a committee to ascertain from the Greenock Corporation the terms upon which the latter will supply electrical energy in the district.

SINGAPORE: *Harbour Electric Supply.*—The electric power station which has been erected at the Keppel Harbour will shortly be opened. The works have a capacity of 1,000 kw., and will supply electrical energy for lighting the wharves, godowns, and workshops, in addition to supplying the power for working the pumps in connection with the dry dock. The estimated cost of the power-house is £55,000.

SOUTHAMPTON: *Wiring Powers.*—At the last meeting of the Town Council the Parliamentary Committee's recommendation that Parliamentary powers be sought to carry on the work of "free or assisted wiring, to instal wires, fittings, &c., through a contractor but not otherwise, and to hire out arc lamps, heating apparatus and cookers, either at a rental, or on the deferred payment system," was adopted.

SPALDING: *Electric Lighting.*—The Council's Electric Lighting Order will be revoked on November 28th next, unless evidence is furnished to the Board of Trade that the Order is being put into force. A canvass of the inhabitants is being made to ascertain the likely demand for electricity.

TURKEY: *Electric Lighting.*—A British Consular report states that the electric lighting of Salonica has been taken in hand, current being supplied from the tramway power-house. Distribution will be by means of overhead wires carried on trellis pattern standards. A certain amount of public lighting will also be carried out.

WESTHOUGHTON: *Electric Lighting.*—Mr. C. D. Taite, Chief Engineer of the Lancashire Electric Power Co., attended a meeting of the local Traders' Association last week, and gave a lecture and demonstration upon the use of electricity for lighting purposes. He emphasised the great economy of using metal filament lamps. He also demonstrated how it could be used for heating, and various domestic purposes.

WORSLEY: *Electric Supply.*—The Lancashire Electric Power Co. have agreed to pay the Council 2½ per cent. of the receipts from the consumers in Worsley until the Council's Electric Lighting order is transferred to the Power Company.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BARNES.—Application is to be made to the Local Government Board to sanction a loan of £4,100 for mains and £3,000 for house services.

COOKSTOWN (IRELAND).—A scheme for the erection of an electricity works, costing £3,665, has been placed before the Council by Messrs. T. L. Miller, Wilson & Pegg. The annual income is estimated at £925, and the expenditure at £575. A resolution has been passed in favour of the proposed scheme.

LONDON: *London County Council.*—The Council invite tenders by November 2nd for two water-tube boilers with induced draught, air-heating apparatus, and machine stokers. Particulars from the Clerk to the Council.

Shoreditch.—The Finance Committee of the London County Council recommend the granting of a loan of £4,110 for mains, switch-board, house services, and meetings.

Stepney.—The Finance Committee of the London County Council recommend the sanction of a loan of £12,000 in connection with the equipment of the Blyth's Wharf Power Station.

RADCLIFFE.—The Council require a supply of low tension three-core paper insulated lead sheathed and armoured cable. Particulars from the Electrical Engineer, and tenders by October 27th.

SOUTH SHIELDS.—New generating plant at an estimated cost of £8,500 is to be installed.

SURBITON.—The Local Government Board have sanctioned the borrowing of £1,266 for electrical purposes.

WIDNES.—A proposal has been placed before the Council for the erection of a large generating station at Weston Point, and for the transmission of electricity at high pressure by means of overhead cables across the Manchester Ship Canal. Negotiations are still proceeding, but in the meantime a municipal scheme at an estimated cost of £4,100 is under discussion.

YARMOUTH.—The Local Government Board have sanctioned a loan of £2,000 for house services.

Miscellaneous

AUSTRALIA.—Tenders are invited by the Deputy Postmaster-General at Melbourne by December 7th for the supply of 2,260 incandescent lamps (metal filament and carbon).

CALEDONIAN RAILWAY CO.—Tenders are invited for stores for the year from January 1st next, including electric lighting materials and fittings, telegraph appliances, telephones, &c. Particulars from the Stores Superintendent, and tenders to the Secretary by November 1st.

DUNDEE.—A recommendation by the Lighting Sub-Committee to erect 16 additional flame arc lamps for public lighting has been adopted.

GRAVESEND.—It has been decided to replace all the Nernst street lamps by metal-filament lamps.

LONDON: *London County Council.*—Tenders are invited for miscellaneous stores for one year from January 1st, 1910, including electric light carbons; fittings; insulating materials; cables and wires; and lamps. Particulars from the Clerk to the Council.

MANCHESTER.—The Corporation Tramways Committee invite tenders for steel-girder tramway rails. Particulars from the General Manager, 65 Piccadilly, Manchester, and tenders to the Town Clerk by October 25th.

Digitized by Google

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Domestic economy centre, Nicholay Road, Islington, N. Builder, J. Stewart, 174 West Green Road, Tottenham.

N.E.—Skating rink, Lower Clapton Road, Clapton. Architects, Fair & Myer, 39 Furnival Street, E.C.

S.E.—Adaptation of premises, Orpheus Street, Camberwell, into cinematograph hall. Architect, B. Crewe, 75 Shaftesbury Avenue, W.C.

Cinematograph hall, Church Passage, Camberwell New Road. Architects, F. Matcham & Co., 9 Warwick Court, W.C.

S.W.—Skating rink, corner of Church Street and King's Road, Chelsea, S.W. Architect, A. W. Hudson, 87 Finsbury Pavement, E.C.

Skating rink, High Street, Putney. Architects, Fair & Myer, 39 Furnival Street, E.C.

W.—Skating rink adjoining Bradmore House, Queen Street and Great Church Lane, Hammersmith, W. Architects, Charles Heathcote & Sons, 110 Cannon Street, E.C.

PROVINCES.

ABERDEEN.—Rink. Secretary, Aberdeen Rinking Co.

ANNFIELD PLAIN.—Church (£1,256). Architect, A. T. B. Kell, 61A Front Street, Chester-le-Street. Builders, T. Reynoldson & Son, Dipton.

BELFAST.—Extensions, G.P.O. (£20,000). Architects, Curry, Ltd., University Street, Belfast.

BURY.—Church school (£3,000). Builder, F. Porter, 29 Walmersley Road, Bury.

COATBRIDGE, N.B.—Extensions to works for Waverley Iron & Steel Co., Coatbridge (£3,000).

Extensions to works for Wilson & Union Tube Co., Coatbridge.

CROYDON.—Theatre. Architect, E. Bates, Croydon.

Rink, London Road. Architect, R. M. Theobald, 300 Noswell Road, E.C.

DURHAM.—Rink. Durham Rinking Co.

FELIXSTOWE.—Isolation hospital. Surveyor, U.D.C., Felixstowe.

JARROW.—Entertainment hall. Builders, Weddle & Son, South Shields.

KEIGHLEY.—School (£5,000). Architect, Moore & Crabtree, Keighley.

MANSFIELD.—Additions, workhouse (£1,150). The Guardians, Mansfield.

MOTHERWELL.—Academy (£35.000). Architects, Cullan, Lochhead & Brown, Motherwell.

NORTHFLEET.—Fire station. Clerk to the U.D.C.

NORWICH.—Factory (£2,137). Architects, Morgan & Buckingham, 1 Upper King Street, Norwich. Builder, W. J. Hannant, Norwich.

READING.—Skating rink (£5,000). Secretary, Reading Rink Co., West Street, Reading.

ROTHERHAM.—Small-pox hospital (£3,500). Engineer, E. B. Martin, Rotherham Town Council.

WINCHESTER.—Tenders are invited for the wiring of the County Council's new offices, St. James Street. Particulars from the County Surveyor, The Castle, Winchester, and tenders to the Clerk by October 25th.

TENDERS RECEIVED AND ACCEPTED

BARNES.—The Council has accepted the tender of the Union Cable Co., Ltd., at £413, for 1,760 yards of cable.

BURSLEM.—The following tenders have been received for plant for extensions at the electricity works:—Buildings, Mr. J. Grant, £1,400; boilers, Messrs. Babcock & Wilcox, £1,100; pipe work, Messrs. Babcock & Wilcox, £108; generating set, Messrs. Siemens Bros. & Co. (Belliss engine), £2,922; condenser, Mr. I. Storey, £1,600; switchgear, Messrs. Crompton & Co., £160.

DARTFORD.—The tender of Messrs. William F. Blay, Ltd., has been accepted at £118 10s., for the construction of a condenser pit at the generating station.

GOVERNMENT CONTRACTS.—During the past month the following contracts have been accepted by the Government departments named:—War Office, electric lamps, Edison & Swan United Electric Light Co., Ltd.; British Thomson-Houston Co., Ltd., telephone sets and parts; British Insulated and Helsby Cables, Ltd., General Post Office, paper core cable, British Insulated and Helsby Cables, Ltd., Johnson & Phillips, Ltd.; cables, submarine cables, Telegraph Construction and Maintenance Co.; detectors and leather cases, General Electric Co., Ltd.; generators, International Electric Co.; wire, copper, hard-drawn, T. Bolton & Sons, Ltd., British Insulated and Helsby Cables, Ltd., Elliott's Metal Co., Ltd., R. Johnson & Nephew, Ltd., Shropshire Iron Co., Ltd., F. Smith & Co., Wilkes, Son, & Mapplebeck, Ltd.

LONDON: *London County Council.*—The Education Committee recommend that the British Westinghouse Co., whose tender for the installation of electric lighting, bells, and telephones at the Paddington Technical Institute has been accepted, shall be allowed to sublet the wiring work to Messrs. G. Foster, Curtiss & Co., of Camden Town.

The tender of Messrs. Isaac Storey & Sons, Ltd., of Manchester, has been accepted at £216 for the supply of condensing plant in connection with the electric lighting of the Paddington Technical Institute.

Marylebone.—Hot water is to be supplied to the lavatories in the Town Hall by means of small Spagnoletti "Therol" electrical heaters.

LOWESTOFT.—The tender of Messrs. Aubert, Grenier & Co. has been accepted for the supply of feeder cables at £783, and that of Messrs. Babcock & Wilcox for two chain grate stokers at £330.

MISCELLANEOUS CITY NOTES

NEW ST. HELENS ELECTRIC TRAMWAYS CO.—A dividend of 1½ per cent. on the preference shares on account of arrears is announced.

ORIENTAL TELEPHONE & ELECTRIC CO.—An interim dividend of 3 per cent., free of tax, is announced on the preference and ordinary shares.

DIRECT UNITED STATES CABLE CO.—An interim dividend of 4s. per share, free of tax, is declared for the September quarter.

CUBA SUBMARINE TELEGRAPH.—A dividend at the rate of 6 per cent. per annum is recommended on the ordinary shares for the year to June 30th.

CALLENDER'S CABLE & CONSTRUCTION CO.—An interim dividend of 5s. per share is announced on the ordinary shares.

MEXICO TRAMWAYS CO.—The usual quarterly dividend of 1½ per cent. is declared for the September quarter.

WASHINGTON TRACTION CO.—Subscriptions have been invited for 400.000 shares of £1 each in this company, which has been formed to construct electric railways in the State of Washington, U.S.A., having a length of 88 miles. The company is also empowered, *inter alia*, to supply electrical energy for all purposes.

CUBAN TELEPHONE CO.—Subscriptions have been invited for an issue of £1,050,000 five per cent. first mortgage convertible bonds.

MONTREAL LIGHT, HEAT & POWER CO.—A quarterly dividend at the rate of 7 per cent. per annum for the quarter to October 31st is announced.

MONTE VIDEO TELEPHONE CO.—A dividend of 6 per cent. per annum is announecd on the ordinary shares for the half-year to July 31st.

PRIMITIVA ELECTRIC LIGHTING CO.—An interim dividend of 5 per cent. per annum is recommended on the ordinary shares for the past half-year.

APPOINTMENTS AND PERSONAL NOTES

The proposal recently made to reduce the salary of Mr. J. H. Cawthra, the Borough Electrical Engineer at South Shields, together with the salaries of the heads of some other departments, was defeated at the last meeting of the Council.

Mr. J. F. Gill has opened an office as Consulting Engineer, at Scottish Provident Buildings, 25 Castle Street, Liverpool. Mr. Gill will specialise in power installations, transmissions, and general economy tests.

Mr. K. A. E. Boshell has been appointed private secretary and personal clerk, at £3 17s. per week, to Mr. A. H. Seabrook, general manager to the Marylebone Corporation Electricity undertaking.

Telegraph Traffic and Movements of Cable Ships.—The chief event in the telegraphic world during the past week was the hurricane in Cuba, which, besides doing a great amount of damage in other directions, also disordered the telegraphic service to some extent, the land-line between Havana and Batabano being the connecting link between the cable system to Havana and the rest of the West Indies. However, repairs were soon effected.—The line between Rome and Constantinople was not working on the 11th inst., and on the 16th inst. the line between Bagdad and Bassorah was down.—Some trouble has also had to be faced by some of the Atlantic cable companies during the past week, but as there are so many lines across the Atlantic, little if any inconvenience is experienced.—With the exception of telegrams to Colon and Panama, telegrams for other places in the Republic of Panama can only be accepted at sender's risk, and the same disabilities apply to telegrams for Costa Rica, Nicaragua, and Honduras, where censorship has also been established.—Spanish communication with Morocco is again experiencing disorganisation, the Tangier-Mogador line being down. Telegrams for the latter place have now to be sent by post from Casablanca.—Cable-repairing steamers during the past month have not had much to do. The *Mackay-Bennett* returned to Halifax, N.S., from Newfoundland, and was there on 30th ulto. The French company's cable steamer *Contre-Amiral Caubet* was in port the whole month, and the *Minia* will, it is expected, return to Halifax on the 30th of this month.—She was recently repairing machinery off Bolt Head.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 5s. to £59 15s. per ton (last week, £59 to £59 10s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The last day for receiving proofs in the bankruptcy of Herbert Shuttleworth, electrical engineer, Cross Court, Briggate, Leeds, is October 28th. The Official Receiver, 24 Bond Street, Leeds, is trustee.

The last day for receiving proofs in the bankruptcy of J. G. Cunnington and H. P. Allison, carrying on business as electrical engineers under the title of Messrs. Laing, Wharton & Cunnington, 7 Great Newport Street, London, is October 26th. Mr. A. Page, 28 King Street, Cheapside, London, is trustee.

Before the Registrar in the King's Bench Division of the High Courts last week, Mr. H. P. Allison, who has traded with Mr. J. G. Cunnington as Messrs. Laing, Wharton & Cunnington at Great Newport Street, London, as electrical engineers, applied for an order of discharge. It was stated that the assets were less than 10s. in the £, and that a dividend of 5s. 4d. in the £ had been declared. The Registrar granted the discharge on condition that the bankrupt consented to judgment for £200.

In the High Courts last week an application for the compulsory winding-up of the Electrobus Co., Ltd., was dismissed.

It was stated in the Companies Winding-up Court on Tuesday, that a scheme for the reconstruction of the British Aluminium Co., Ltd., is being matured, and in consequence of this the petitioners for the compulsory winding up of the company have agreed to allow their petition to stand over for a month.

La Capital (Extensions) Tramways Co., Ltd., is to be wound up voluntarily, and Messrs. E. A. Lazarus and F. Thursby have been appointed liquidators. A meeting of creditors will be held at 62 London Wall, E.C., October 27th, and creditors are requested to send in particulars of their claims by November 1st.

A meeting of the Improved Electric Glow Lamp Co., Ltd., will be held at 658 Salisbury House, London Wall, E.C., on November 22nd, at noon, to hear the liquidator's account of the winding up.

ILLUMINATION OF BLACKPOOL FLYING GROUND.—The British Westinghouse Electric & Manufacturing Co., Ltd., are lighting the Aviation Grounds at Blackpool with 36 "Arcturus" flame-arc lamps. These have out-door choking coils for running the lamps four in series on a 200-volt, 83-period circuit.

THE ABBEY ELECTRIC CO.—Mr. J. W. Beswick, of Temple Chambers, 33 Brazenose Street, Manchester, has been appointed representative of this company for the Manchester district.

SOME MAWDSLEY MOTOR CONTRACTS.—Messrs. Mawdsley's, Ltd., of Dursley, Glos., have in hand, or have recently completed, the following contracts:—Nine motors aggregating 510 h.p. for equipment of granite quarry; fourteen motors aggregating 480 h.p. for new rubber factory in Manchester; booster set for Agent-General for the Cape; booster set for the Crown Agents for the Colonies; dynamos and boosters for new generating stations at Tewkesbury and Chippenham; hydro electric installation, comprising turbine, dynamo, and motors for sugar factory in Mauritius.

VENNER TIME SWITCHES.—Among recent orders placed with Messrs. Venner & Co. are 100 time switches for Bedford and 48 for Cork, both of these following on several previous orders. The firm have also received from the North Metropolitan Electric Supply Co. an order for time switches for controlling the street lighting at Hertford.

AGENCY.—Messrs. Mawdsley's, Ltd., of Dursley, Glos., have appointed Mr. S. Mansel Jones, of Western Mail Chambers, Cardiff, and Wind Street, Swansea, their sole agent in South Wales.

Leeds Section, I.E.E.—The first general meeting of the forthcoming session of the Leeds Section of the Institution of Electrical Engineers will be held at the University, Leeds, on Wednesday next, October 27th, at 7.15 p.m., when Mr. W. M. Rogerson will deliver his Address as Chairman of the Section. Mr. A. B. Mountain, Chief Electrical Engineer to the Huddersfield Corporation, will afterwards read a Paper entitled "Notes on Superheated Steam," and will deal with the following points:—Method of superheating steam by separately fired superheaters and other types of superheaters. Practical limits of superheat; the advantages claimed:—Increased evaporation of boilers; increased efficiency of engines; reduced losses in piping, &c.; the danger of applying superheated steam to engines which have not been specially designed; the difficulty of selecting suitable oil, testing the same, and methods of feeding. The following Papers have been arranged for during the session:—November 17th: "Some Experiments on Single and Stranded Fuses," by W. T. Maccall; December 15th: "Metallic Filament Lamps: their Possible Beneficial Effects on Supply Undertakings," by G. Wilkinson and R. McCourt; January 26th: "Equitable Charges for Tramway Supply," by H. E. Yerbury; February 23rd: "Notes on Overhead Lines," by W. B. Woodhouse; March 16th: "Electrical Machinery for Iron and Steel Works," by E. S. Saunders; April 20th, annual general meeting.

COMPANIES' MEETINGS AND REPORTS

SWANSEA IMPROVEMENTS & TRAMWAYS CO.—At the half-yearly meeting last week, the report and accounts were adopted. After placing £1,000 to reserve and depreciation fund, and meeting preference dividends, a balance of £4,552 is carried forward.

UNITED ELECTRIC TRAMWAYS OF CARACAS.—The report for the period of eighteen months from January 1st, 1908, to June 30th, 1909, states that up to March 15th, 1908, the contractors carried on the undertaking. Since then the net receipts amounted to £10,346, and after meeting debenture interest and placing £425 aside for the redemption of mortgage debenture stock, there is a balance of £894, which is carried forward.

METROPOLITAN DISTRICT RAILWAY CO.—A private meeting of the four per cent. guaranteed stockholders and the non-cumulative five per cent. preference stockholders was held on Tuesday, when the Board recommended, we understand, that 75 per cent. of the interest arrears should be funded into a security ranking equally with the guaranteed stock, and the balance of 25 per cent. written off. It has been left to the Board to complete the details of their proposal.

COMPANIES TO BE STRUCK OFF REGISTER.—Notice is given that the names of the following electrical companies will be struck off the register of Joint Stock Companies within three months unless cause is shown to the contrary:—Chitty Dynamo & Motor Co.; Warrington & District Electric Light & Power Co.

CUBA SUBMARINE TELEGRAPH CO.—The report for the half-year to June 30th shows a balance of £17,859 to be dealt with, including the amount brought forward. After adding £3,000 to reserve, and meeting the preference dividend, a dividend at the rate of six per cent. per annum is declared upon the ordinary shares, and the sum of £7,159 is carried forward.

Shipping Rates to South Africa.—The National Electrical Manufacturers' Association has obtained a concession from the South African Steamship Conference regarding the freight of electric lamp glass shades. Hitherto these have been rated in the first class, while gas lamp shades have been carried at the second class rate (a lower rate). The matter was taken up with the Conference by the Association, and the South African lines in the Conference have agreed that in future common glass shades for electric lamps, packed in cases, shall be carried at the second class rate.

CROSBY LOCKWOOD & SON'S NEW BOOKS.

ALTERNATING CURRENT MACHINES: Being the second volume of "Dynamo Electric Machinery: Its Construction, Design, and Operation." By **S. SHELDON, A.M., Ph.D., HOBART MASON, B.S., E.E.,** and **ERICH HAUSMANN, B.S., E.E.** Eighth edition, completely revised. 368 pages, 236 illustrations. Large crown 8vo, **12s.** net. [*Just Published.*

ELEMENTARY ELECTRICAL CALCULATIONS. A Manual of Simple Engineering Mathematics, covering the whole field of Direct Current Calculations, the basis of Alternating Current Mathematics, Networks and Typical Cases of Circuits, with Appendices on special subjects. By **T. O'CONOR SLOANE, A.M., E.M., Ph.D.,** Author of "The Standard Electrical Dictionary," &c. 314 pages, 43 illustrations. Crown 8vo, **9s.** net. [*Just Published.*

ELECTRICITY in FACTORIES and WORKSHOPS: Its Cost and Convenience. A Handbook for Power Producers and Power Users. By **A. P. HASLAM, M.I.E.E.** 328 pages, 70 illustrations. Large crown 8vo, **7s. 6d.** net. [*Just Published.*

DYNAMO, MOTOR, AND SWITCHBOARD CIRCUITS FOR ELECTRICAL ENGINEERS. A Practical Book dealing with the subject of Direct, Alternating, and Polyphase Currents. By **WILLIAM R. BOWKER,** Consulting Engineer and Street Railway Engineer, Professor of Physics in the University of Southern California, Los Angeles. Second Edition, revised and greatly enlarged. 180 pages, 130 diagrams. Medium 8vo, **7s. 6d.** net.

TELEPHONES: Their Construction, Installation, Wiring, Operation and Maintenance. By **W. H. RADCLIFFE** and **H. C. CUSHING.** 180 pages, 125 illustrations. Foolscap 8vo, **4s. 6d.** net.

WIRELESS TELEPHONY IN THEORY AND PRACTICE. By **ERNST RUHMER.** Translated from the German by J. ERSKINE MURRAY, D.Sc., F.R.S.E., M.I.E.E. With an Appendix by the Translator. 258 pages, 145 illustrations. Demy 8vo, **10s. 6d.** net.

Complete Catalogue, Post Free on Application.

PREVENTION OF WASTE DUE TO CONDENSATION IN STEAM PIPES

THE losses in fuel and water due to the condensation in steam pipes are often very considerable, and though there are methods of returning the water of condensation to the boilers, the pipes are generally cleared by means of steam-traps, and much of the heat in the water is lost. As an alternative arrangement, Mr. G. Wilkinson (Borough Electrical Engineer, Harrogate) has developed a new apparatus which is being placed on the market under the name of the "Wilkinson Thermal Column."

The apparatus works due to the fact that directly a body of steam is cut off from the source of supply it cools rapidly, and the pressure drops. It will be noted, on reference to the accompanying diagram, that when there is no water of condensation in the sump *A*, the steam has free access up the rising pipe *C* into the top receiver *E*, which is fixed some five or six feet above the tops of the boilers. Directly sufficient water of condensation drains into the sump from the steam range through the inlets *B*, the bottom of the rising pipe *C* is immersed in water, and then the rising pipe *C* and the chamber *E* are cut off from the source of steam supply. The steam already impounded quickly drops in pressure, and therefore the water rises up the pipe *C* into the chamber *E*. Directly the sump *A* has been drained into *E*, steam follows up the rising pipe *C*, establishing equilibrium of pressure on the top of the

SKETCH TO ILLUSTRATE WORKING OF WILKINSON "THERMAL COLUMN."

water in *E*, when the said water is free to gravitate through the pipe *F* and check valve *G* into the boiler or boilers to which it is connected.

The receiver *E* is of such capacity that the amount of water collected in the sump and entraining pipes during the period of time when the receiver is discharging to the boiler and being refilled is less than it will hold. Should at any time the top receiver and rising pipe become full of water, due, say, to the priming of a boiler, opening out of a length of cold steam pipe, or any other abnormal cause, an automatic relief valve is provided on the receiver, which allows such excess of water to escape until the rising pipe becomes again charged with steam, when the apparatus resumes its normal work. Such flooding will not occur under normal working conditions. The apparatus has, we are informed, been in successful operation in the Harrogate Corporation Electricity Works for nearly twelve months, and has proved itself to be reliable and economical. It is stated that the condensed steam can be lifted from the sump and returned to the boilers with a maximum drop in temperature of less than one degree Fahrenheit per foot of lift. Further, there is no outlet to the atmosphere, and the water is returned at a temperature closely approaching that of the steam. Further particulars can be obtained from Mr. Wilkinson (Beech Mount, Harrogate).

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

SIGNS AND SHOP LIGHTING.—The General Electric Co. (71 Queen Victoria Street, E.C.) have brought out a new list of shop lighting fittings, including lantern reflectors and advertising signs. Since the advent of Osram lamps, which have given so much impetus to this class of lighting for illumination, decoration, and advertisement, a large number of special fittings, signs, &c., have been introduced, enabling full advantage to be taken of them.

TIME SWITCHES.—A booklet from the Reason Manufacturing Co. (Brighton) describes the company's latest form of hand-wound time switches. These are similar in most essentials to the electrically-wound switches to which we referred last week. As in the electrically-wound pattern, the power for actuating the switch is provided by a spring, which is quite distinct from the mainspring of the clock. An important difference, however, between the electrically-wound and hand-wound types is that in the former the switching spring is geared to the main spring, while in the latter it is entirely independent, and is wound up by hand, as is the main spring itself. There is sufficient power in the latter to keep the clock going accurately for 14 days, and the switching spring is of ample strength to perform the operations of "quick-make" and "quick-break" once each per day during this period.

IRON-CLAD SWITCHGEAR.—A list received from Messrs. Parmiter, Hope & Sugden (Hulme Electrical Works, Manchester) deals with a new standard pattern of iron-clad switch embodying some recent improvements. This is a double-pole switch with laminated phosphor-bronze blades, built up in the form of the letter Y, and making contact between solid brass blocks. The base is of block china. To meet the demand for a combined switch and fuse for small motor circuits, a double-pole switch with "Ajax" cartridge fuses, arranged in a box with china partitioning walls has been developed. This can be obtained in two forms, a semi-enclosed and a totally enclosed interlocked pattern, and in two sizes for 25 and 50 amperes respectively. Some neat patterns of iron-clad fuse-boxes are also included in this list.

ARC LAMPS.—The latest leaflet of the Abbey Electric Co. (17 Victoria Street, S.W.) contains details of the Abbey flame arc lamp. This lamp, which is of simple construction, entirely without clockwork, is made in the 12-14 hour and 20-22 hour sizes for one pair of carbons, and the largest of these does not exceed 48 in. overall length. A full description of the mechanism was given in ELECTRICAL ENGINEERING, Vol. IV., Manchester Exhibition Supplement, page 46.

Standardisation in Engineering.—In his presidential address to the Association of Engineers-in-Charge, Mr. Henry Adams summarised the history of engineering standards, and described the work of the Engineering Standards Committee. Referring to illuminating standards, he mentioned the Helium vacuum tube lamp of Mr. Nutting, of the U.S.A. Bureau of Standards. Such a lamp, he said, is free from atmospheric conditions, leaves little to be desired in steadiness, is readily reproduced, is of good colour, and could be probably constructed in 5 and 10 c.p. sizes, with quartz tubes. The standarisation of catalogues and algebraic notation was also referred to.

Birmingham Local Section I.E.E.—The annual dinner of the Section will be held at the Grand Hotel, Colmore Row, Birmingham, on Friday, November 12th, at 7 for 7.15 p.m. Mr. R. R. Morcom will preside.

Electrical Illuminations at the Hudson-Fulton Celebrations.—Our American contemporaries contain numerous photographs of the electrical illuminations in New York and the neighbourhood which played a prominent part in the recent Hudson-Fulton celebrations, and were carried out on an unprecedented scale. Buildings were outlined with a profusion of incandescent lamps, and a double lane of lamps extended the whole five-mile route of the carnival parade; in this alone about 30,000 lamps were used. A conspicuous feature of the scheme was the device known as the Ryan scintillator, consisting of two groups, each consisting of nine 31 in. and one 24 in. arc projector equipped with colour screens. The effect of the beams from these was heightened by the use of numerous jets of steam from a 200-h.p. boiler, upon which the light was directed. Smoke effects from aerial bombs were also employed, and a variety of fantastic effects were produced. The apparatus required a current of about 1,500 amperes.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 14th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

17,461/08. **Iron-clad Switchgear.** V. Hope (Parmiter, Hope & Sugden). Special constructions of iron-clad switches and switch-fuses are described, in which the switch blades act independently of the operating handle. Both quick make and break are obtained, and partial contact is avoided. Three claims, seven figures.

19,482/03. **Trolley Head.** F. G. Holmes. Two pivoted spring-controlled arms with rounded tops are attached to the trolley head. These come over the top of the wire and prevent the trolley wheel leaving it. When passing suspension ears or cross-overs, the arms are forced outwards. A cord attached to the trolley arm rope causes the arms to open when the rope is pulled. Two claims, three figures.

19,847/08. **Lengthening Life of Metal Filaments.** Glühlampenwerk Anker Ges. It has been found that blackening of bulbs can be prevented by admitting a small quantity of phosphoretted hydrogen or arseniuretted hydrogen into the vacuum. The introduction of the gas is effected by coating the leading in wires or glass pedestal with mixtures comprising either one part phosphorous and two parts phosphum or one part phosphorous, one part P_2H_2, and one part phosphum. These yield phosphoretted hydrogen when heated. To obtain arseniuretted hydrogen, a mixture of two parts As_2H_3 and one part phosphum is used. Two claims.

20,098/08 and 72/09. **Continuous-current Generator or Motor.** A. Boeckel, O. Grünberg, J. K. Krukovski, and E. Luxembourg. The armature and field system are geared together and rotate at the same speed in opposite directions, while the brushes remain stationary. The number of commutator segments is twice the number of armature coils, each of which is connected to the two segments at opposite sides of the commutator. For a two-pole machine, four brushes are placed at right-angles, the opposite brushes being connected together. If the field were to rotate at twice the speed of the armature, the commutator would have to be divided into three parts. The second specification describes a construction in which the rotary field is produced by means of a three-phase stationary winding supplied from the armature by means of slip-rings. The armature is connected to the commutator as above, and commutating poles projecting over an extension of the armature are provided. A compensating winding is also provided on the stator. The machine is applicable as a motor or a generator, and the high relative speed effects a reduction in cost of material. Three claims, eight figures.

20,895/08. **Automatic Regulation of Three-phase Load Equalising Systems.** J. S. Peck. This device is for the purpose of reducing the excitation of the flywheel-machine when it commences to supply energy to the mains instead of only to the load. It comprises a rheostat operated by a motor with two windings arranged so that a reverse current alters the direction of rotation. One winding is supplied from a series transformer and the other from a shunt transformer connected across two of the mains. Two claims, two figures.

21,596/08. **Automatic Block Signalling.** British Thomson-Houston Co., Ltd. (*General Electric Co., U.S.A.*). In this system, which utilises the "skin effect," both rails are conductively continuous, and sources of A.C. E.M.F.s are connected at intervals across the rails. Track relays are connected in shunt to short lengths of rail, and these relays operate the signals. As even with low frequencies, the impedance of steel rails is high compared with the resistance, the pressure drop along these lengths will be sufficient with a frequency of 50 or 60 cycles to work the relays. Thirteen claims, eleven figures.

5,717/09. **H.-T. Overload Relay.** Allgemeine Elektricitäts-Ges. A H.-T. trip coil shunted by a safety fuse has been employed, but replacing the fuse is dangerous. To eliminate this danger, the releasing magnet has a primary winding connected to the H.-T. mains, and a L.-T. secondary winding short-circuited through a fuse. When the fuse blows, the circuit of the secondary winding is opened, and the switch tripped. Two claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Rawlings, Handcock, and Dykes [Sheathing of wires] 24,548/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Regulation of power factor in A.-C. systems] 25,556/08; Owen [Machine for insulating wires] 7,531/09.

Dynamos, Motors, and Transformers: Lang, and Johnson-Lundell Electric Traction Co. [Motor control] 20,721/08.

Electrometallurgy & Electrochemistry: Lévy [Manufacture of caustic soda] 20,787/08; Boult (*McNaughton*) [Primary cells] 28,285/08.

Instruments & Meters: Kilroy, and Eversheds & Vignoles, Ltd. [Speed indicators] 20,596/08; Thompson [Speed indicator] 20,852/08; Smith and Phillips [Indicating and recording instruments] 28,522/08.

Switchgear, Fuses, & Fittings: Statter [Time-element device] 20,468/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Lightning arresters] 22,134/08; Lawton and Whatson [Tilting lamp-shade holders] 27,816/08; Wirth and Beck [Apparatus for control of machines at a distance] 5,811/09; Wieckmar [Cut-outs for overhead lines] 9,803/09; Zucker Fabrik Frankenthal [Motor-starter] 12,258/09.

Telephony & Telegraphy: Smith [Telephone systems] 2,151/09; McKenna (*General Acoustic Co.*) [Telephonic stenography] 9,350/09.

Traction: Dawson [Securing doors from guard's van] 20,325/08; McCulloch and Panton [Emergency brakes] 20,394/08; Taylor [Brake blocks and collector shoes] 20,472/08; Wagner [Railless vehicles] 21,490/08; Peter [Emergency signals] 23,286/08.

Miscellaneous: Bigge, Butt, and Webb [Induction coils] 19,885/08; Brandes [Lamp standard] 20,536/08; Appleby and Drew [Boards for controlling time signals] 24,618/08; Murday [Clocks] 26,259/08; Boult (*Jackson and McNaughton*) [Clocks] 28,286/08.

The following Specification is open to Inspection at the Patent Office before Acceptance, but is not yet published for sale.

Incandescent Lamps: Coolidge [Manufacture of metal filaments] 282/09.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

19,866 of Oct. 22nd, 1895. **A.-C. Meters.** R. Belfield (*O. B. Schallenberger, U.S.A.*). This patent describes methods of arranging the pressure and current coils of induction motor meters, so as to obtain two fields at right-angles and in quadrature, including the use of an auxiliary short-circuited coil in the same axis as one of the main coils. Means for compensating for temperature error by a variable air-gap in the inductance, are also covered.

20,028 of Oct., 24th, 1895. **Commutator Brushes.** F. J. and R. Chaplin. A brush composed of a bundle of fine crimped copper wires with or without a copper gauze covering.

20,243 of Oct. 26th, 1895. **Gutta-percha Substitute.** E. Hornung. Glue is precipitated from an aqueous solution by means of tannic acid, alum or other material. The product is mixed with a small quantity of india-rubber and pulverised cork or fibrous materials, and dried.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Boron carbide electrodes] 13,381/05.

Distribution Systems, &c.: H. G. Osburn [Flexible wiring conduit] 11,597/00; J. Pfister [Impregnating wooden poles] 14,518/02; F. Everhart and J. Dossert [Cable coupling] 14,520/04; H. Hirst and C. E. Gunner [Conduit fitting] 14,767/04.

Dynamos, &c.: C. Wüst-Kunz [Multiple-speed A.-C. induction motor] 13,239/01; Siemens Bros. & Co. and H. Berry [Commutators] 13,588/05.

Electric Ignition: A. J. Boult (*H. C. Mueller, U.S.A.*) [Multiple coil apparatus] 13,148/05.

Incandescent Lamps: H. Birkbeck (*Phelps Co.*) [Two-filament lamp with thermal flasher] 13,156/05.

Instruments and Meters: W. L. Wise (*Union Elektricitäts-Ges.*) [Induction motor meter] 11,695/00.

Storage Batteries: I. Kitsee [Regenerating plates] 13,427/05; H. W. Cox, Ltd., and A. C. Mitchard [Plates] 13,471/05.

Switchgear, &c.: S. Jevons and C. H. Offord [Automatic time-switches] 13,266/01; P. H. Thomas [Circuit-breaker with mercury-vacuum tube break] 4,663/04; Siemens Bros. & Co. and H. Berry [Motor starter] 13,587/05; Siemens Bros. & Co. (*Siemens Schuckertwerke*) [Switches] 13,590/05.

Telephony and Telegraphy: W. J. Hancock [Receiver for wireless telegraphy] 13,327/05.

Traction: A. J. Boult (*F. H. Daniels, U.S.A.*) [Rail bonds] 13,526/99; P. M. Justice (*American Automatic Switch Co.*) 14,741/03; J. Maudet [Rail joint] 14,691/04; P. J. Pringle [Rail cleaner] 13,120/05; Siemens Bros. & Co. (*Siemens Schuckertwerke*) [Haulage of ferry boats] 13,591/05.

Miscellaneous: T. A. B. Carver [Electric jacquards for looms] 14,345-6/96; J. J. Meldrum [Refuse destructor] 14,614/96; Clarke, Chapman & Co., and H. Walker [Lifts] 13,577/05; B. H. Thwaite [Electric treatment of plants] 13,607/05.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

Mr. W. C. Goodchild writes to say that the principle of Mr. George Wilkinson's method, decribed in our last issue, of returning the condensed steam in the pipe-range to the boilers is the same as that of the "Automatic Steam Loop" known since 1891. Mr. Wilkinson replies that the "steam loop" is quite incapable of draining a steam-pipe range. (Page 926.)

Tests of a new Howden (Zoelly)–Siemens 6,000-kw. set at Manchester show a steam consumption (excluding excitation and auxiliaries) of 13·8 lbs. of steam per kw.hr. at full load with 28 in. vacuum and 140° F. of superheat. The tests also show exceptionally good results at lower loads. We also publish a well-illustrated description of the machine. (Page 927.)

The new Blyth's Wharf generating station of the Stepney Borough Council was opened yesterday. The building is principally of ferro-concrete, and already contains one 1,000-kw. double-current turbo set which was moved from the old station, and a new 2,000-kw. turbo-alternator. A feature of the station is the 6,000-volt switchboard on the Reyrolle ironclad system, and the use of the Merz-Price protective system throughout. Continuous current at 2×240 volts is provided for, as well as a high-tension supply. (Page 931.)

Recent developments and improvements in the O.S. wiring system are described on page 931.

Action is being taken by the Wolfram (Tungsten) Metal Filament Lamps, Ltd., and the General Electric Co., Ltd., to restrain the Welsbach Incandescent Gas Light Co., Ltd., from using the words "Welsbach Aur" upon their metal filament lamps. It is alleged that this is a false trade description under the Merchandise and Trade Marks Act, 1887, inasmuch as the lamps in question were not invented by and are not manufactured by Baron von Welsbach. (Page 935.)

The hearing of the action brought by Messrs. J. H. Holmes and Co. against the Associated Newspapers, Ltd., for alleged infringement of the Clatworthy patent for the electric driving of printing presses, was concluded on Thursday last. Evidence was given on the Wednesday by Mr. Swinburne and Prof. Boys on behalf of the defendants. Mr. Justice Neville has dismissed the action on the ground that the patent is invalid. (Page 935.)

Digitized by Google

At the meeting at the Court of Common Council last week, it was decided to authorise the Works Committee to undertake further experiments in connection with street lighting. (Page 936.)

A wireless telegraph station on the Balsillie system has been erected in Darley Dale, Derbyshire.—The Australian Postmaster-General is calling for tenders for the erection of wireless telegraph stations.—It is announced that the South African Government have decided to establish wireless telegraph stations at Cape Town and Port Elizabeth. (Page 936.)

On Thursday last the King was enabled personally to open the new Tuberculosis Institute at Montreal by transmitting from Chichester a current impulse which was automatically relayed over land lines and an Atlantic cable to work a relay in the Institute. This relay controlled a motor mechanism which opened the doors of the Institute and hoisted the national flag. (Page 937.)

Mr. S. J. Watson's inaugural address as Chairman of the Manchester Section of the Institution of Electrical Engineers took the form of a survey of various points of interest in connection with the development of electric supply undertakings during the past fifteen years. (Page 937.)

Two new flame arc lamps have recently been placed on the market; one is a converging carbon lamp, and the other a vertical carbon lamp, especially suitable for street lighting. We also describe a combined oven and hot-plate, which is a development of the "Bastian" quartz tube radiator. (Pages 937 and 938.)

The Beckenham Council have declined to join in a proposal to promote a Bill for securing electric wiring powers.—Brighton Corporation recommend that the Board of Trade should seek powers to grant licences for the use of trolley 'buses.—The annual accounts of the Kingston-on-Thames Corporation Electricity Department show a deficit of £1,251.—The Highways Committee of the London County Council report against the use of trolley 'buses in the Blackwall and Rotherhithe tunnels.—A proposal by the County of London Electric Supply Co. to link up their Wandsworth and City Road stations is disapproved by the City Corporation and the London County Council. (Page 939.)

A turbo-generator set is to be installed at Brighton, and condensing plant at Eastbourne. Mains are to be extended at Sheffield; flame arc lamps are required at Epsom and Ilford; arc-lamp lowering gear at Warrington, and feeder cables at Walthamstow. Tenders are required for a public lighting scheme at Lucknow. (Page 939.)

In the House of Lords on Tuesday, an amendment was made in the Electric Lighting Acts (Amendment) Bill by which railway companies may take a supply from unauthorised distributors, but not for the purpose of traction. (Page 940.)

The net profit on the past year's working of the Edison & Swan United Electric Co. was £421. No dividends will be paid. The accounts of Messrs. Ferranti, Ltd., show a net balance of £307. The accounts of the Clyde Valley Electric Power Co. show a net profit of £4,084, and those of the Cleveland & Durham Electric Power Co. a loss of £3,667. (Page 941.)

Mr. F. H. Medhurst was found shot in a hotel at Croydon on Tuesday. (Page 941.)

Among the specifications published by the Patent Office on Thursday last was one by P. McCullough and J. A. Panton for air-operated track brakes in which the shoes have carborundum ribs. J. G. Statter protects improvements in the "Statter" time-element relay by which an adjustable time-lag is obtained and the temperature error is automatically corrected. A method of covering insulated wires with a uniform metal sheathing which will not easily buckle is described by J. J. Rawlings and others, and the British Thomson-Houston Co. have protected a method of automatically regulating the power-factor of A.-C. systems by employing a synchronous motor taking a leading current, the excitation of this motor being controlled by a modified Tirrill regulator. W. O. Smith and W. Phillips protect a construction of dash-pot for the indicating arms of recording instruments. The time-lag can be adjusted to any desired amount, and a thin oil enabling small variations to be registered is used. Eight patents taken out by L. Renault and relating to automobiles have been revoked on the ground of inadequate manufacture in this country; two of these relate to sparking plugs. A patent by W. Claypoole for an insulating material has been revoked under Section 26 of the Patents Act. (Page 942.)

ARRANGEMENTS FOR THE WEEK

FRIDAY, OCTOBER 29th.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, Clerkenwell. Paper to be read:—"The Development of the Marine Steam Engine," by A. T. Barber.

MONDAY, NOVEMBER 1st.

P. and O. Batti-Wallahs' Society.

8 p.m. Smoking Concert at the Holborn Restaurant, London.

TUESDAY, NOVEMBER 2nd.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Meeting at the University. Paper to be read:—"The Electric Ignition of Internal Combustion Engines," by J. W. Warr.

Institution of Civil Engineers.

8 p.m. Ordinary meeting at 25 Great George Street, London. The President, Mr. J. C. Inglis, will deliver an Address, and afterwards distribute the medals and prizes awarded by the Council.

WEDNESDAY, NOVEMBER 3rd.

Institution of Electrical Engineers: Birmingham Section.

7.30 p.m. Opening meeting of the Session at the University, when the Chairman, Mr. R. K. Morcom, will deliver his Inaugural Address.

THURSDAY, NOVEMBER 4th.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster, London. Paper to be read:—"Technical Popular Fallacies," by A. S. E. Ackermann.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London. Mr. C. E. S. Phillips will deliver his Presidential Address.

CORRESPONDENCE

PREVENTION OF WASTE DUE TO CONDENSATION IN STEAM PIPES.

To the Editor of Electrical Engineering.

Sir,—Referring to the description on page 923 of your last issue, it may be of interest to record that a model apparatus to demonstrate the return of condensed steam to boilers, on the same principle as that adopted by Mr. Wilkinson, was shown at the Taunton Electrical Exhibition in 1891 under the name of the "Automatic Steam Loop."

11 Mill Hill Road, Derby. October 22, 1909.

Yours truly. W. C. Goodchild.

Mr. Wilkinson has sent us a copy of the following letter he has received from Mr. Goodchild, and also his reply:—

Sir,—Since writing to the Editor of Electrical Engineering (copy of my letter enclosed), I see the description of your apparatus also appears in the *Mechanical Engineer* and *Mechanical World*. It therefore occurs to me that I should communicate direct with you as to the absence of novelty in your invention.

Yours truly, Derby. October 22, 1909. W. C. Goodchild.

[*Copy of reply to above.*]

Sir,—In reply to your letter of the 22nd inst., the "Steam Loop" has been well known for the last thirty or forty years. It is a device, however, which is quite incapable of draining a steam-pipe range, and has never been successfully applied for that purpose.

Believe me, Yours faithfully, Harrogate. October 23, 1909. Geo. Wilkinson.

THE NEW 6,000-KW. GENERATING SET AT THE MANCHESTER CORPORATION ELECTRICITY WORKS

Extremely Low Steam Consumptions.

THE 6,000-kw. Howden (Zoelly)–Siemens turbo-generator, which is the latest addition to the Stuart Street electricity supply station of the City Electricity Department at Manchester, was started up in the early part of September, and since then has been running on full load about eighteen hours a day. The tests, made three weeks ago, have given results exceeding all anticipations, and they show steam consumptions even less than the very low figures obtained with the Willans-Siemens 5,000-kw. set at Stuart Street, which was completed in May last year. By the courtesy of Mr. S. L. Pearce, the Chief Engineer of the Manchester Corporation Electricity Works, we are enabled to publish the results of these tests, and also to give a complete description of the machine, which is the largest turbine of the Zoelly type yet constructed

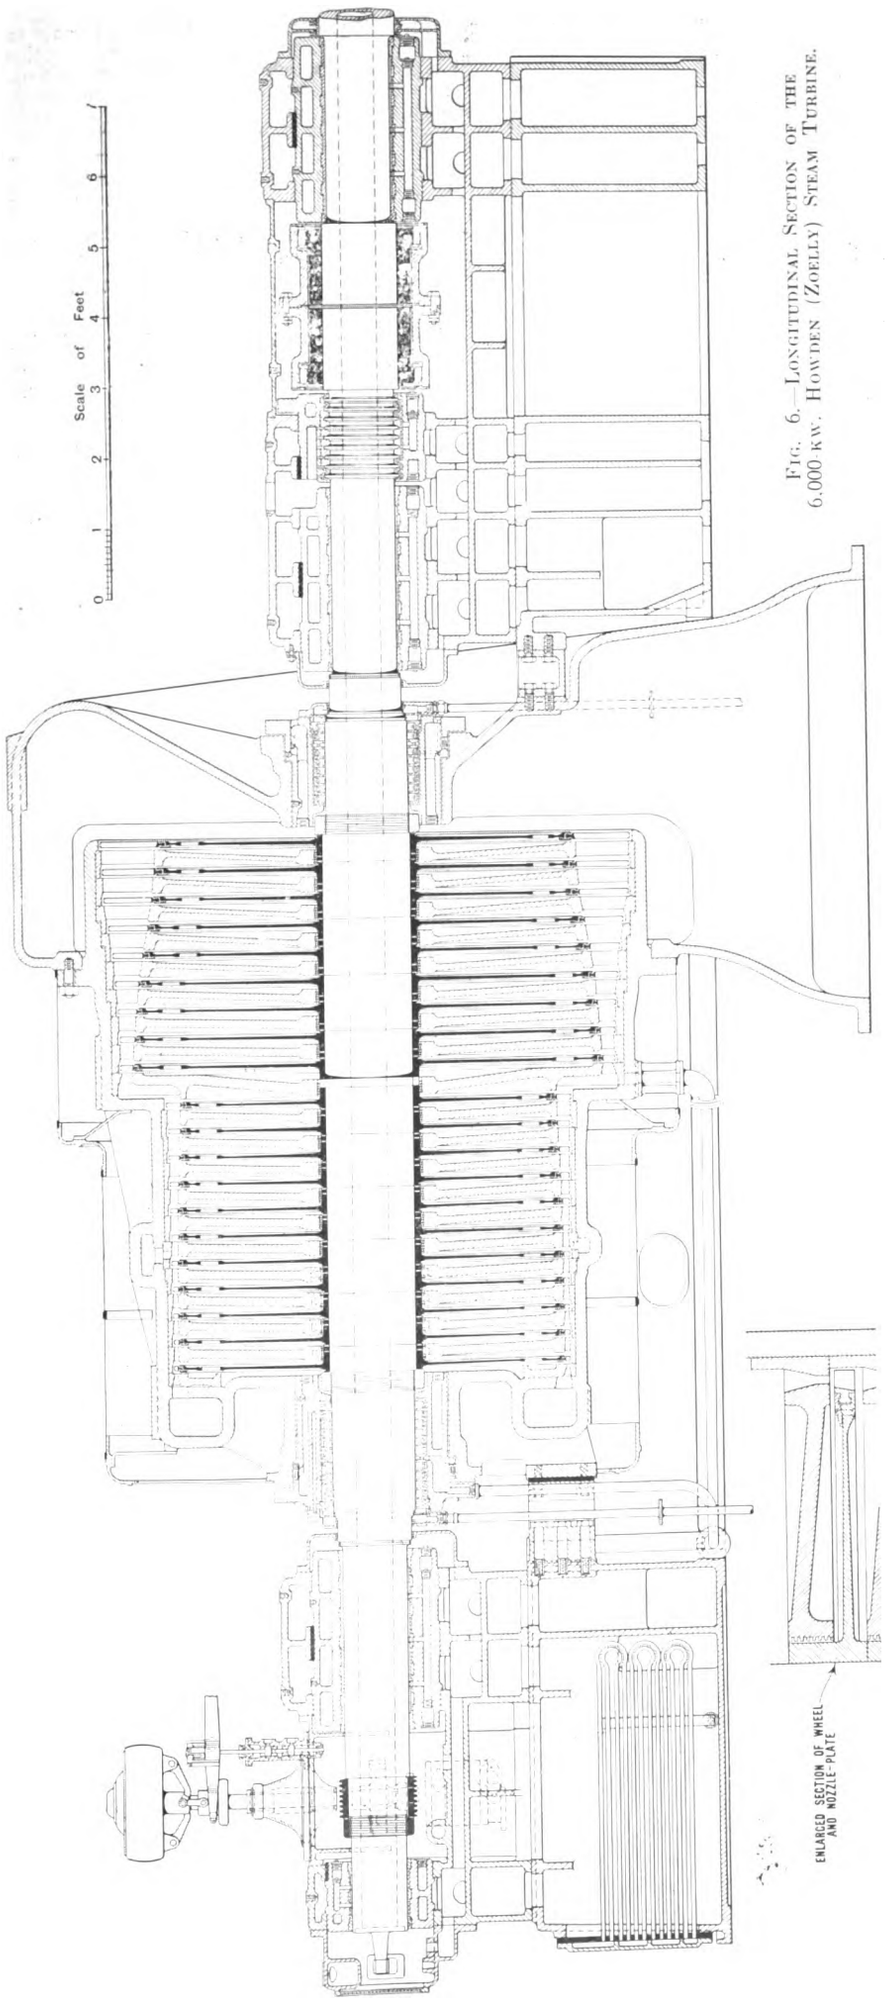

FIG. 6.—LONGITUDINAL SECTION OF THE 6,000 KW. HOWDEN (ZOELLY) STEAM TURBINE.

5,000-kw. machine already mentioned; the alternator efficiencies as obtained on the test-bed at Messrs. Siemens' works; and, lastly, the thermo-dynamic efficiencies of the turbine after allowance has been made for the alternator efficiencies. It is seen that the extremely low figure of 13·8 lbs. per kw.-hour was obtained at full load with a 28-in. vacuum and 140° F. of superheat, and the excellent results at quarter-load should also be noticed. It should be added that the figures in the table do not include the power required by the auxiliaries or for excitation, which was as follows:—

	Condenser Pumps.	Fan Motor.	Field Excitation.	Total.
25% overload	360 kw.	21·4 kw.	22·9 kw.	404·3 kw.
Full Load.....	376·2 kw.		25·6 ,,	401·8 ,,
¾-Load	356·6 kw.	18 kw.	25 ,,	399·6 ,,
½-Load	333·3 ,,	16·8 ,,	23·3 ,,	373·4 ,,
¼-Load	346·6 ,,	18·1 ,,	18·2 ,,	382·9 ,,

The duration of the tests was six hours at full load, and three hours at the other loads.

Fig. 3 is a series of curves, which Mr. Pearce has plotted to show the steam consumption of the new set, and he has also corrected the results so as to be comparable with the 5,000-kw. Willans-Siemens set. The turbine of the Willans-Siemens set was originally rated at 5,000 kw., but it was found that it would run at 6,000 kw. continuously with but a slight loss in efficiency, and the alternator coupled to it is a 6,000-kw. machine practically identical with that of the later set.

Although the construction of the Zoelly type of turbine is probably familiar to a large number of our readers, this article would hardly be complete without a description of the machine itself. The Zoelly is an impulse turbine, and the steam is expanded through the fixed guide blades instead of by the moving blades as in the Parsons or reaction type, and the velocity only is employed in the moving blades. This enables a far greater clearance to be employed between the rotor and the stator, and also diminishes the end thrust on the bearings. The radial clearance is about $\frac{3}{16}$ in. (5 mm.), and the clearance in the axial direction about the same. The cylinder is divided up into a number of stages, twenty in the case of the Manchester turbine, and the steam is expanded down from stage to stage; as the pressure gets lower in the successive stages the number of blades has to be increased, and the diameter is therefore larger at the low-pressure end. A detail drawing at the bottom left-hand corner of Fig. 6 shows the method of dovetailing the blades into the rotor, which is one of the features of the Zoelly turbine. With the exception of a few blades in the high-pressure stages, where they are short, they taper from the root to the tip, this giving great rigidity. The balancing

Digitized by Google

is very perfect, and we found the vibration of the machine barely noticeable. A photograph of one of the guide-wheels is given in Fig. 4. These are in halves, so that the upper portion of the guide-wheels can be removed with the upper half of the casing, as seen in Fig. 2.

The following are the main dimensions of the machine:—

Diameter of high-pressure turbine over blading ..	67¾ inches.
Diameter of low-pressure turbine over blading ...	90 1/16 ,,
Diameter of turbine shaft	11 ,,
Revolutions per minute.....	1,000
Overall length of turbine and alternator	40 feet.

The usual bye-pass arrangement is provided, by which high-pressure steam can be fed into the lower stages if an emergency load is required, and with this it is possible to increase the output of the machine to even 10,000 kw. if necessary. Without the pass-valve

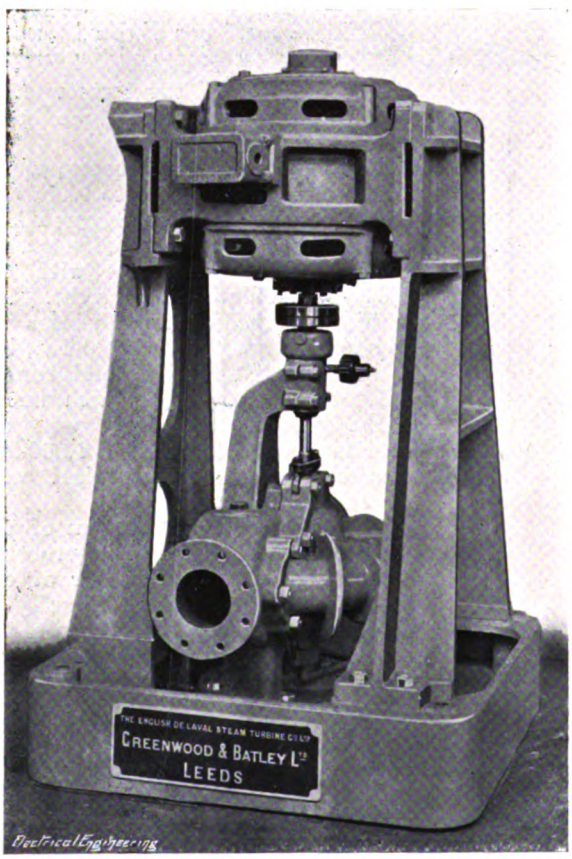

Fig. 7.—The De Laval Centrifugal Hot-Well Pump.

being opened the turbine will comfortably develop 8,000 kw.

The makers claim the following advantages for their turbine:—

The turbine has only from one-third to one-fifth the number of blades of the ordinary multistage reaction turbine for the same power and speed, and the average velocity of the steam being low, the wear on the blades is practically negligible.

There is ample clearance between all the moving and stationary parts, and no adjustment is necessary either in the thrust or the main bearings.

As the principle of the turbine entirely eliminates the axial thrust, balancing pistons are not required, and the leakage incidental to such pistons is avoided.

The greatest advantage can be taken of superheat, as, owing to the form of casing adopted, there is no danger of warping. The turbine is not affected by great variation of temperature, and will work quite satisfactorily with steam at a temperature as high as 700° F.

The lubrication is entirely automatic, and the cost of oil is very little on account of its being used over and over again.

The governing is exact and instantaneous, and the speed practically remains constant under widely varying loads; as steam is not admitted in gusts, as in the case of most reaction turbines, the paralleling of alternators is very much simplified.

As no part of the turbine except the bearings is lubricated, the exhaust steam is pure, and may be condensed and used as feed water.

Each running wheel is separately balanced, and after erection the whole of the rotating system is balanced, the result being that the turbine runs dead true, no vibration whatever being perceptible.

The steam consumption does not increase after running some time, as is the case with other types of turbines, and is independent of the attention and skill of the engine-room attendants.

The alternator is an almost exact duplicate of the machine on the Willans-Siemens set already referred to, the only difference being slight alterations in detail. It is a 6,000-kw. machine generating three-phase current at 6,500 volts between phases and 50 cycles per sec., and is of the salient pole type. It was made by Messrs. Siemens Bros. Dynamo Works, Ltd., at their Stafford works. The machine has forced ventilation, as its sister machine, and the plant for this is installed in the same small room adjoining the engine-room, in which the fan and dust filter of the other machine are running. Details of the method of ventilating and of the construction of the alternator were published in Electrical Engineering of May 14th, 1908.
